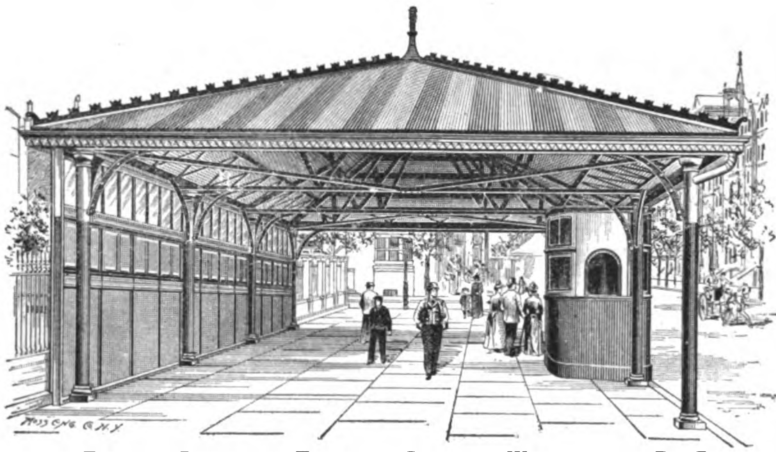
The side adjacent to the Treasury Department, or what would ordinarily be called the side next to the fence, is made of glass and iron so that it can be removed at pleasure. On the curb side there is a small transfer station made of sufficient size to accommodate one person, and at the same time a small stove, to furnish heat in severe cold weather. The building is open at all other points. The view shows the construction of the building so well that little need be said. The only obstruction to ordinary traffic is the small house or transfer station, and this is located so near the curb that it practically amounts to no obstruction at all. There is not a particle of woodwork used in the building, the construction being entirely of iron and glass, so that there is no fire risk whatever. The roof is covered with the Berlin Iron Bridge Company's patent anti-condensation corrugated iron, with corner cresting, which with the round supporting columns with ornamental caps and bases, gives the building a very ornageneral surrounding, and at the same time forms a very comfortable and convenient shelter for transfer passengers.



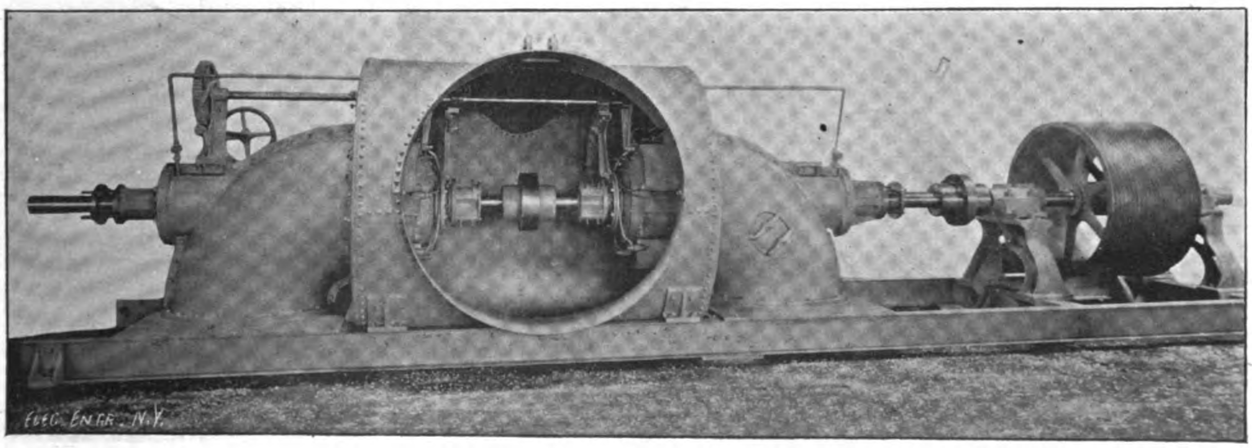
TROLLEY PASSENGER TRANSFER STATION, WASHINGTON, D. C.

NEW AMERICAN TURBINES FOR THE MARQUETTE, MICH., CITY LIGHT PLANT.

The accompanying engraving illustrates the water wheels and flume which were recently installed in the City of Marquette, Mich., in its new city lighting plant. The outfit was designed and manufactured by the Dayton (O.) Globe Iron Works Company, and consists of a pair of 22-inch special new American turbines to operate under 80-foot head and to develope 900 horse-power. The wheels are placed in a horizontal flume, made with castiron heads, with wrought steel shell. The flume is mounted on steel I-beams and cross girders, which are placed on solid masonry. The water is conducted to the turbines in a wrought steel supply pipe 6 feet in diameter, and is discharged from the wheels through the castiron quarter turn at each end of the flume and steel draft tubes into the tail water. The feeder pipe is furnished with a revolving valve to shut off the water when desired. This feature, however, is not shown in the illustration.

The power is transmitted from the wheels to a countershaft by means of a gearing of twenty ropes 1⅓ inches in diameter, which travel at a speed of 7,000 feet per minute, and from thence the power is transmitted to the dynamos The driving sheave is shown on the water wheel shaft.

The whole power plant is first class in every detail, designed and constructed to give perfect satisfaction and to stand



DOUBLE TURBINE, BUILT BY THE DAYTON, O., GLOBE IRON WORKS CO. FOR THE MARQUETTE, MICH., CITY LIGHTING PLANT.

the immense pressure due to a head of 80 feet. The manufacturers feel justly proud of this and other plants which they have constructed to meet the requirements of these very high heads.

We may add that the entire power-plant was furnished by the Dayton Globe Iron Works Company.

THE LITTLE GIANT TRACK CLEANER AND RUSSELL SNOW PLOW.

ONE of the most annoying things which electric railroads have to contend with in winter is snow and sleet on the tracks, and at other times, as well, dirt is frequently a bar to quick traffic. It is not an easy matter to design a track-cleaner which shall be thoroughly adapted to its work and at the same time operate smoothly, but an excellent example filling both these requirements is the Little Giant Track Cleaner, built by the W. E. Austin Manufacturing Company, of Norway, Me., and illustrated in Fig. 1.

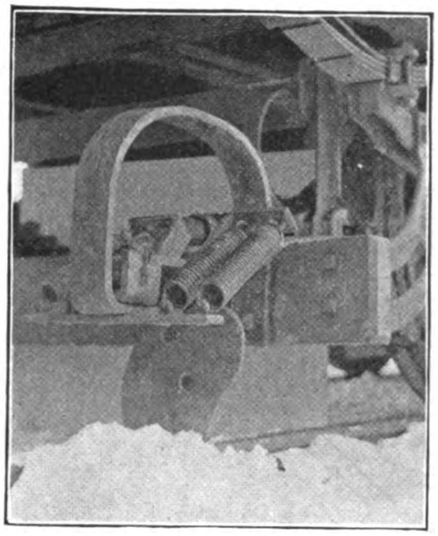


FIG. 1.—THE LITTLE GIANT TRACK CLEANER.

One of the essential features of this apparatus is the constant pressure exerted by the scraper on the rail. The arrangement is such also that one or both scrapers can be run, so that if one rail is salted, the scraper over the opposite rail alone need be used.

As the scraper is attached to the truck and not to the body of the car, it makes no difference how much the car oscillates or how rough the track is. In the case of low rails, one or two inches below the roadbed, the narrow blade of the scraper always finds the track.

Fig. 2 illustrates a cheap snow plow designed and constructed by Mr. F. B. Russell, and in use on the electric railroad at Norway, Me., during the present severe winter. The whole apparatus weighs only 2½ tons and requires only one man to operate it. Its cost did not exceed $250. The scraper at the rear of the plow is another application of the track-cleaner shown in Fig. 1.

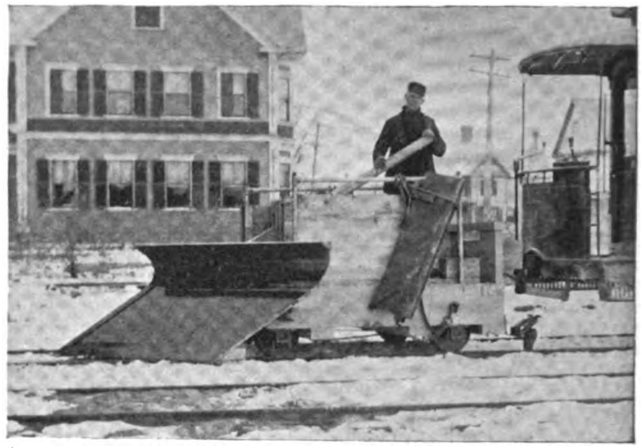

FIG. 2.—THE LEE SNOW PLOW.

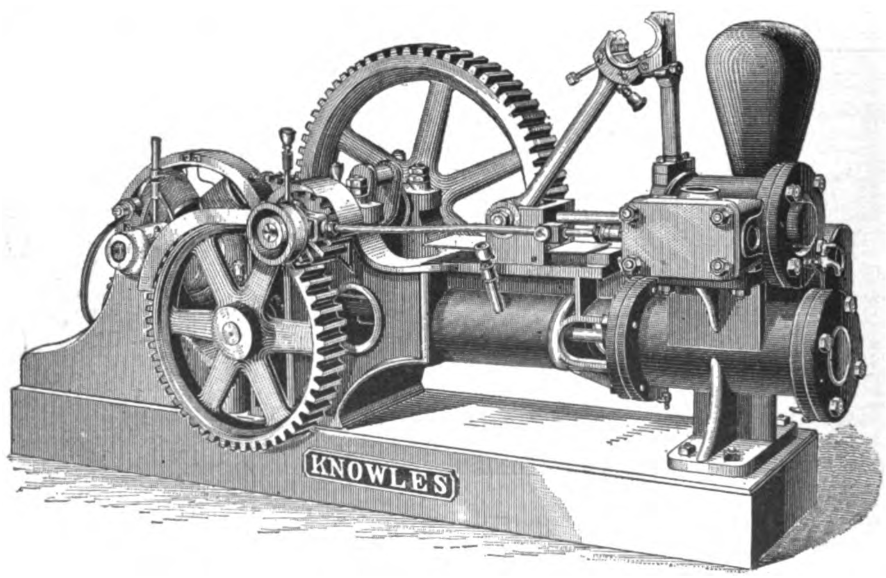
KNOWLES ELECTRIC POWER PUMPS.

The special catalogue of electric power pumps of the Knowles Steam Pump Works, 93 Liberty street, New York, with offices in Boston, Chicago and London, will be perused with much satisfaction by the trade. It is compiled from knowledge of apparatus already built in the shops of the company, and well tested in actual service in many countries. Such types have been selected for description and illustration as are likely to meet the needs of the largest section of buyers and users of pumps by various classes. The pamphlet has been written with great discrimination and intelligence, and is confessedly suggestive rather than arbitrary in its general bearing. Various points on which the two great essentials of pumping machinery, economy and effective work, depend are discussed. It is shown that, starting from the coal pile, a direct acting steam pump of the ordinary commercial type will require a greater coal consumption for a given service than a power pump of similar capacity, electrically operated, in spite of the intermediate efficiency losses in engine, generator and motor.

Another point of weight, which has often to be considered, is the compactness and flexibility of the connecting elements between the pump and its source of power supply. Properly insulated wires may be located in cramped spaces or imbedded in walls, where steam pipes would be entirely out of the



THE KNOWLES COMBINATION STEAM AND ELECTRIC PUMP.

question. Attention is called to many other advantages of electric pumping machinery for architects, waterworks, manufacturing processes and for general purposes. Each and every pump made by the Knowles Steam Pump Works is fully guaranteed.

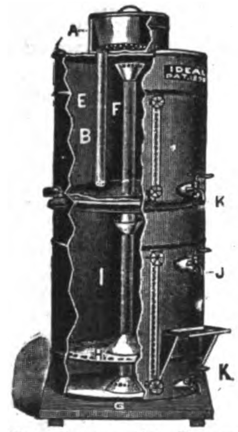
The catalogue, which covers forty-four pages, includes much special and miscellaneous information, more particularly on the various forms of pumps and their successful installation. Specially deserving of notice is the combined steam and electric power pump, which is illustrated in the accompanying engraving. This apparatus is particularly adapted to locations where steam is required only part of the time for heating or power purposes, while pumping must be carried on continuously and electric power is available for use in the intervals. The connecting gear is designed to be quickly connected or disconnected. Cut gears are used throughout, and the crossheads are made with a special take-up for lost motion. Crank shafts are carried in large babbited bearings. The size illustrated has a steam cylinder 4½ inches in diameter, the water cylinders being 3¾ inches and stroke 6 inches.

THE IDEAL IMPROVED STEAM OIL REFINER.

The accompanying engraving illustrates the "Ideal" improved steam oil refiner manufactured by the Purity Oil Filter Manufacturing Company, of 900 Water street, Pittsburg, Pa.

The waste or drip oil is poured into the receiver A, where all coarse articles are arrested by a fine strainer. The oil passes down through pipe B and is discharged in water that has been warmed to a temperature of 150 degrees, by a steam coil that is directly under the water, but not in it. All the heat is by radiation. It is consequently impossible to get the oil or water so hot that it will boil. The waste oil gathered each day is poured in the same way until the chamber E is filled, which will take four or five days; the next day's oil will displace the oil poured in the first by overflowing it into the pipe F passing out in water the second time in chamber I. Here it cools. When the oil rises so that it can be drawn from faucet J it is cold and ready for use again.

A glass gauge is on each chamber that indicates the amount of oil and water that may be in each. The faucets K are for



THE IDEAL OIL FILTER.

regulating the water and for drawing off the sedimentary matter that may accumulate in the refiner. The pan H catches the refuse that may settle on it. It is the full diameter of the shell. This can be withdrawn at any time without drawing off the oil and water, by lifting off the refining chamber E and taking hold of the pipe in the center and pulling up slowly. When out it can be emptied, cleaned in a few minutes, then replaced and allowed to gravitate to its original position, which will not disturb the oil. The refining chamber may then be replaced and steam connections made as before.

The steam coils are ½-inch diameter pipe. Only enough opening in the discharge valve to free the coil of condensation is required. Very little steam is used. It will be seen that the oil has passed through no filtering material or substance. Consequently there is nothing that will require to be renewed except the water.

THE EDISON ELECTRIC COMPANY, New Orleans, La., have increased their power plant by the addition of a 300-horse-power Ball engine, manufactured by the Ball Engine Company, Erie, Pa.

THE FUCHS DRY CELL BATTERY COMPANY has been formed by H. J. Katz, J. V. Falvey, A. Barrington, T. T. Ryan and C. D. Jearance, with a capital stock of $100,000.

LAIRD'S POCKET TOOL.

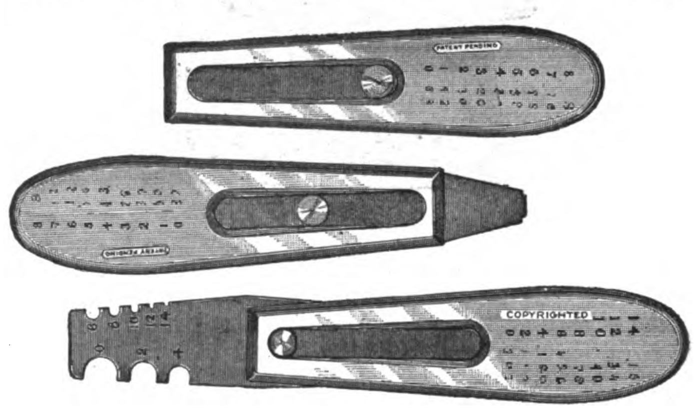
This tool is designed for that class of workmen who need a wire gauge occasionally, who have to carry a screwdriver all the time, and especially those that have wiring calculations to perform.

The wire gauge is the standard Brown & Sharp, ranging from No. 0 to No. 14, a new form of slot being used that reduces the cost of manufacture without impairing the accuracy or utility of the gauge.

The screwdriver is made from the best steel, finely tempered, and is a good emergency or pocket tool from its peculiar shape, which adapts it to anything from the large screws in a main cut-out or switch to the small ones in a key-socket or rosette.

The gauge and screwdriver are on one piece of steel, which is provided with a handle of aluminum, and when the blade is closed the whole outfit is only the size and weight of a common pocketknife, perfectly smooth and neat in appearance.

The flat surfaces of the handle are stamped with figures representing sizes of wires and decimals of ampere feet, and



LAIRD'S ELECTRICIAN'S POCKET TOOL.

by this system, wiring calculations that by the area or resistance method are considerably complicated, are reduced to a single multiplication, and the process is so plain that any one can understand the principles and application. The tables may be learned and then any problem can be solved mentally, something that can hardly be done by any of the present methods.

Through the years of electrical progress, the men that were able to make their own wiring computations have been the exception rather than the rule, and one reason for this is that men who are good mechanics are seldom very handy in the higher mathematics. To provide for this wiring charts by various authors are used and are of great value.

They practically agree in their figures, and electricians that follow them carefully get good results. This method of ampere feet is so arranged that the result agrees with standard rules, and the calculation can be made quicker than it can be looked up in a chart.

These tables are copyright, and are furnished only with the combination pocket tool shown. They are stamped on the handle and are also printed on a neat sheet, together with other valuable information, and the whole will be mailed prepaid to any address for $1 by Laird & Bowers, Montpelier, Vt.

NEW ENGLAND NOTES.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., have just completed for the Citizens' Gas Company, at Bridgeport, Conn., two large buildings, one 63 feet wide by 171 feet long, comprising a purifier house, a meter house and a valve house, and the second building, 44 feet wide by 122 feet long, comprising a generator house, a scrubber house and engine room. The side walls are of brick and the roof trusses of steel covered with corrugated iron.

REMINGTON & HENTHORN, of Providence, R. I., have dissolved by mutual consent. The business will be continued by Geo. H. Remington & Co., at 210 Westminster street, where they will attend to securing United States and foreign patents, and prosecute allied branches of their profession.

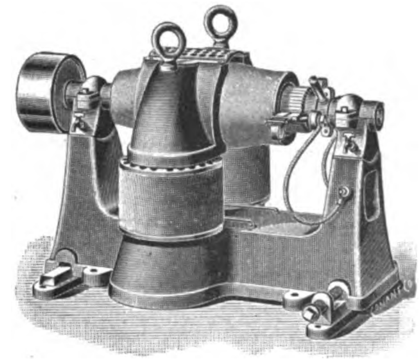
THE AMERICAN ELECTRIC COMPANY has been organized at Kittery, Me., with a capital stock of $20,000 to manufacture electric gas lighters and burners. E. H. Brocke, of Quincy, Mass., is President and W. E. Thomas, of Somerville, Mass., is Treasurer.

THE NEW BATES ELECTRIC MOTOR.

The H. N. Bates Company, of 240 Congress street, Boston, Mass., have been long known in the electrical business as manufacturers of friction clutches and shafting and have now gone into the direct electrical business by getting out a line of electric motors which they are manufacturing themselves, under the superintendence of Mr. L. I. Fletcher, for years associated with the Lowell Electric Light Company, Lowell, Mass.

Particular attention has been given to the production of a medium speed motor of high efficiency, and at the same time the speed is very much less than is common in bi-polar machines.

Every motor is provided with a pair of sliding rails and necessary belt tighteners, and is also fitted with lugs in case it



BATES ELECTRIC MOTOR.

is ever desirable to attach it rigidly to the floor or foundation. The frame of each machine is so built that it can be adapted to 110, 220 and 500 volts, all parts being interchangeable.

All motors above one horse-power are provided with fireproof automatic starting boxes of the latest design so made that if, from any cause, the current is shut off, the switch closes and prevents accident to the armature.

The Bates Company believe that the method of insulation used in both their armature and field coils is so perfect that the danger of burn-outs is reduced to a minimum, especially in the 500 volt type, where the most danger exists. The company is prepared to manufacture at short notice special motors for any speed or voltage.

A DISCUSSION OF THE ARC CARBON QUESTION.

Mr. Hugo Reisinger, of 38 Beaver street, New York, who is the sole importer of the "Electria" Nuernberg carbons for arc lights, as well as other specialties in the carbon line, has just addressed the following argument to central station managers and others interested in the successful operation of arc lights:

The necessity of using the best grade of carbons obtainable wherever not only a really efficient but also an economical arc light service is required, has repeatedly been pointed out by eminent electricians. While in many cases much money is expended for dynamos, arc lamps, etc., in order to insure the above-mentioned advantages, it is difficult to account for the tardiness of some station managers in adopting the best grade of carbons, as a means to get the best return for the money invested in an arc light plant.

Since I introduced the "Electra" High Grade Nuernberg Carbons to the trade, the leading electrical stations have certainly shown their appreciation of their uniform high quality and efficiency by adopting them for their arc lighting, and I am pleased to say that the sales of the "Electra" carbons have been rapidly and continually increasing.

Yet I feel that some station managers have not given enough importance to the carbon question, and that a great many of them are still satisfied with fairly good results in the matter of illumination; and while they think that the price they pay for carbons of lower grades is reasonable, they are under the impression that they are operating economically.

There is no doubt that in many cases the apparent higher price of the best grade of carbons has had the effect of deferring their adoption; but as with machinery and other articles, the first cost should not be the only consideration, quite apart from the fact that all points considered, the best grade of carbon obtainable will always prove the cheapest.

I am convinced that if consumers of arc light carbons will only make a careful test of the carbon they are using against the "Electra" carbon, they will discover that taking the candle-power produced at an expenditure of a certain amount of current, the life, steadiness and dust as important factors, the high grade "Electra" carbons will be by far more economical than any other carbon, foreign or domestic manufactured, or, putting it more plainly, the "Electra" carbon will cost less per given hours of burning than any other carbon which may be listed at a lower price.

There are other carbons in the market for which highest efficiency is claimed, but the many tests to which the "Electra" carbons have been submitted by leading stations, conclusively show that the "Electra" carbon will furnish more light for the same power expended on the lamp, or the same light for less power, that they will burn steadier and produce less dust than any other make, either foreign or domestic, the difference in the efficiency of the "Electra" carbons and other imported carbons being from 10 to 25 per cent.; while the difference in the efficiency between the "Electra" carbons and the best make of domestic carbons, is from 25 to 30 per cent.

While, therefore, the question to be determined by consumers of carbons resolves itself into the relative cost of the carbons, and of the power and fuel they will save, I feel that managers of electric light stations cannot fail to see that my "Electra" carbons are worthy of a trial, and I am sure that after having placed their first order with me, they will use no other carbons thereafter.

In order to enable you to make your own tests of the "Electra" carbons, I shall be very glad to send you samples of any sizes you may desire, free of charge, and also quote you my very best discount on orders for large quantities, or on contracts for yearly requirements.

It would seem that these statements as to the net economy and higher efficiency of a higher-priced article are well worthy consideration, especially as Mr. Reisinger wants every manager to try it for himself.

THE NATIONAL UNDERGROUND CABLE CO.

We learn that the National Underground Cable Company has just received from the Central Union Telephone Company a very large contract for telephone cable for the City of Toledo, the contract covering also the laying, jointing and connecting of the cables, etc.

This is about the largest single telephone cable order given out in the year 1896, and the National Company is to be congratulated upon the receipt of it. This progressive and enterprising company has booked during the week also several large orders for electric light and street railway cables; and is rapidly making itself felt in the line of telegraph cables, for the manufacture of which it has a special department in its factories at Harrison, N. J.

WESTERN NOTES.

W. D. BALL & CO., Consulting Electrical and Mechanical Engineers, 1625 Monadnock Block, Chicago, is the style of the firm succeeding the partnership of Ball & Allen, which has been dissolved, Mr. Allen retiring. The new firm is composed of Mr. W. D. Ball, who has been well known in engineering circles for several years, and Mr. F. E. Drake, formerly the general agent and assistant manager of the Standard Electric Company. The new firm will continue to do consulting and engineering work, Mr. Ball taking the technical end, while Mr. Drake will have the management, caring for the general business.

MR. F. E. DRAKE, who has for years been identified with the Standard Electric Company in the capacity of general agent and assistant manager, has entered the firm of W. D. Ball & Co., Consulting Electrical and Mechanical Engineers, with offices No. 1625 Monadnock Block, Chicago. Mr. Drake's long experience in the commercial field of the industry and his practical knowledge of the requirements of central station, isolated plant and general practice will be of much value to the new firm and its clients.

THE PACKARD MOGUL LAMP is slowly but surely working its way into public favor for large lighting. The Electric Appliance Company, the general Western agents for this specialty, has closed several large contracts for these lamps during the past few months. The Ravenwood platforms and station on the Milwaukee division of the Chicago and Northwestern Railway are lighted by these lamps, and their superiority for this kind of work is plainly apparent. The Electric Appliance Company furnish special shades and street hoods for these lamps, which largely increase their efficiency.

MR. S. F. B. MORSE, of the Marquette Building, Chicago, has returned from a short trip which he recently made to the West, taking in Colorado Springs and the gold region. Mr. Morse, who had not been well for some time, was very much benefited by his little vacation. He also visited Cripple Creek, and although there was quite an exodus of fortune-seekers from Chicago to that region, Mr. Morse was quite pleased to return to Chicago, and his many friends are glad to see him back again.

THE "BABY" KNIFE SWITCH has, it is said, leaped into public favor with about the same rapidity that the new "baby" usually does. The Electric Appliance Company is meeting the demand for this new specialty by carrying a large stock at very low figures. It is furnished in round or square bases in 15 and 25 ampere single and double pole.

THE ELECTRIC SPECIALTIES COMPANY, of 1351 Broadway, Oakland, Cal., report business as excellent, and say that they are three months behind their orders.

Department News Items will be found in advertising pages.

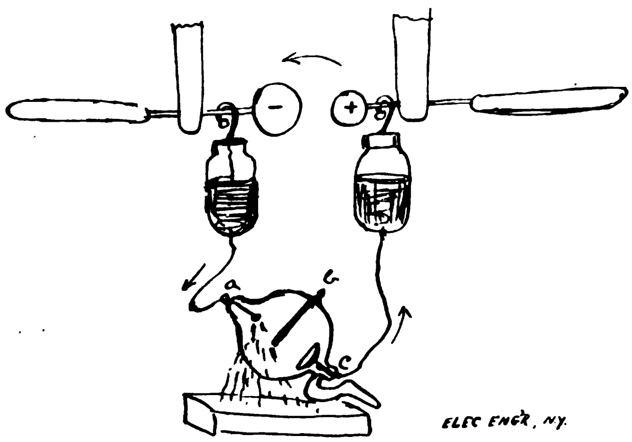
ELECTRIC LIGHTING.

ROENTGEN RAYS FROM THE ANODE TERMINAL.

Elihu Thomson

IN a recent note published in your journal concerning some experiments I made in tracing the Röntgen rays to their source at the metal terminal within the Crookes tube, from which they proceeded in straight lines, this terminal was spoken of as the cathode. I find that Professor Rowland has recently made some experiments which would point to its being the anode which evolves the rays, and on going over the polarities of the Wimshurst machine which I used in my experiments and the direction of the discharges I find that the terminal is indeed the anode from which the rays emanate.

There can be no question about it in the tube which I have used. Before reading Professor Rowland's observations I had been led to doubt its being the cathode which gave the rays and had, in fact, noticed that the terminal on the negative side of the Wimshurst machine is the one which gives the rays. During the discharge of the jars, however, this is not the cathode, but really the anode. These observations of Professor Rowland confirmed by my own would seem to at least point to the fact that the rays are not the same as what are



PROF. ELIHU THOMSON'S ROENTGEN RAY TUBE.

called cathode rays, but that the Röntgen rays are, properly, anode rays.

I have used a fluorescent screen of barium platino-cyanide enclosed within a dark tube with a sight hole at one end, and I find that by having a patch of metal on the side of the Crookes tube, as soon as this metal piece comes between the anode and the screen all fluorescence of the screen ceases, but the slightest displacement either way produces fluorescence on the border of the screen.

This observation shows without doubt that the rays proceed in straight lines from the terminal within the tube, which turns out to be the anode. Experimenting with the Wimshurst machine enables one to be quite positive as to the direction of flow, while with a Ruhmkorff the tendency to oscillatory currents may disturb the observations, and, of course, with high frequency apparatus the anode and cathode are rapidly interchanged.

I enclose a sketch of the arrangement which I have used. I have found that one of the tubes I have is particularly active, and its history is, briefly, this: It was a tube having an aluminum cap as terminal c, an iluminum disc as terminal a, and between the two a platinum sheet mounted on a stem at the side of the bulb, b. It was used on high frequency currents, terminal c being left disconnected for fear of melting down the platinum piece by concentration of the cathode rays or radiant matter of Crookes thereon. During the use the vacuum gradually improved and finally the tube became insulating so that a three-inch spark would not send any discharge through the vacuum. At the same time, the terminal a, or aluminum disc, was melted down into a confused mass. The improvement of the vacuum was doubtless due to the carriage of metallic platinum from terminal b to the sides of the bulb, which absorbed the residual gas. It remained in this condition for a few days.

It was then decided to heat the tube for the purpose, if possible, of driving out the gas which had been taken up by the platinum deposited on the sides of the bulb. This was carefully done, and it was found that the tube became conducting once more and remained so. It, indeed, became, apparently, just in the right condition of exhaustion to give the best results.

I have endeavored to get Röntgen pictures with other Crookes tubes, but none have appeared so satisfactory as this one, and some which are apparently all right for exhibition of the Crookes phenomena give no Röntgen rays. I think it would be desirable in constructing such tubes to seal in a small flat or slightly convex surface of aluminum as an anode and a somewhat extended cathode disc of aluminum, and a third terminal of sheet platinum for the sole purpose of adjusting the vacuum, as by the use of the third terminal, with discharges passing therefrom such an amount of platinum may be deposited on the glass as will carry the vacuum up to the desired point, which is just short of that which makes the vacuum insulating in character.

MR. EDISON'S RESEARCHES ON ROENTGEN RAYS.

BY E. J. HOUSTON AND A. E. KENNELLY.

MR. THOMAS A. EDISON, after numerous experiments on Röntgen rays with about 150 different glass vacuum tubes, has communicated the following information to us for publication:

1. There is no apparent advantage in obtaining very high vacua in the Crookes tubes employed for photographing the shadows of metal gratings. The effect of a very high vacuum is to require a greater voltage to produce fluorescence. The best degree of vacuum is that at which the internal luminescence or striae in the tube just disappears and fluorescence of the walls remains. The Röntgen rays are still produced even when internal striae are observed but are enfeebled.

2. Thin walls are preferable to thick walls in the glass vacuum tubes. A thick wall will fluoresce very brilliantly and become very hot. A thin wall will emit rays having greater photographic power, but may scarcely fluoresce visibly, and will remain very cool. This is proved by a number of experiments, of which the following is one: A tube of the shape roughly indicated in the sketch, Fig. 1, has its walls blown thick in the zone of A C, but thin at B. When this tube is exhausted and excited, the thin part B, which is in the most actively excited area, remains cool and photographically very active, while the glass becomes hot in the ring A C. If B be made thick and A C thin, the glass at B may become melted by the heat, but its photographic power is reduced, although its visible fluorescence is greater. Walls ⅛ inch thick become unmanageable by excessive heat and rapid melting.

3. For any given tube in a given condition of exhaustion, the photographic power of the tube; i. e., the swiftness with which it produces a developable image is roughly proportional to the square of the fluorescent candle-power or total visible fluorescent light given out by the tube.

4. The duration of exposure has been found to be as follows: With the most sensitive plates in an ordinary plate holder having a light vulcanized fiber cover of about 1-32 inch thickness, the time necessary for obtaining a good shadowgraph of a metal grating or grid is less than one second, when the tube

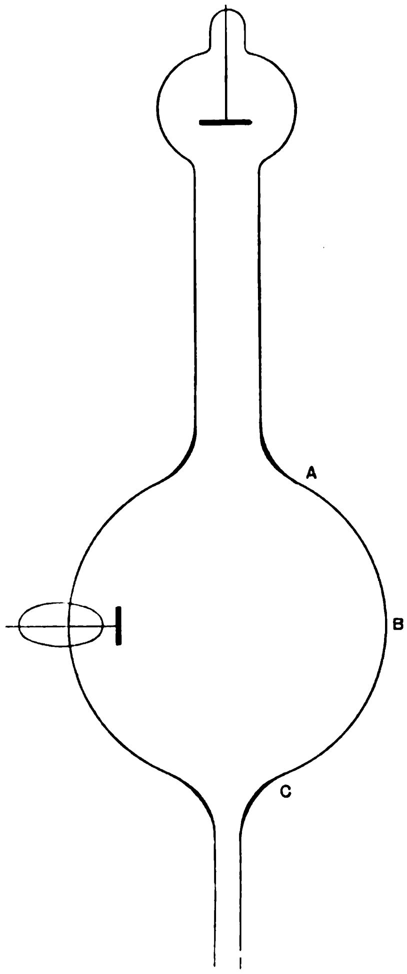


FIG. 1.

is within a quarter of an inch of the grating, and, therefore, about ⅜ inch from the sensitive plate. At two feet distance the time for an equally good shadowgraph is approximately 150 seconds, and at three feet distance the time increases to about 450 seconds. Roughly the duration of exposure may be reckoned as proportional to the square of the distance.

5. Of the photographic plates as ordinarily employed for photographic purposes, the medium rapid plates appear to be the most suitable for Röntgen rays, i. e., to require least duration of exposure. Rapid plates and slow plates appear to be equally unfavorable in regard to sensitiveness for Röntgen rays compared with medium plates. To test this a composite sensitive plate was made from five strips, cut from plates of different photographic sensitiveness, and the shadowgraph of a series of metal bars was taken with the bars at right angles to the strips of the composite plate. For the same exposure and same development the depth of the shadowgraph images produced did not bear any apparent relation to the photographic sensibilities of the strips or their sensitometer numbers. The medium rapid plate gave much the deepest images in every such experiment.

6. The power of a tube having a given degree of exhaustion and disposition of electrodes, increases with the surface area of its fluorescent walls. Thus a large vacuum tube exposing a large total fluorescent surface has a more rapid action on a sensitive plate, i. e., requires less exposure, but will require more voltage and more electric power to excite. On the other hand, for a given distance of the tube from the plate, the image is sharper and less distorted as the tube diminishes in size. Consequently, for a given tube, used without a diaphragm, a fairly great distance and long exposure produced the sharpest photographic effects. A small tube will produce a sharp image at a lesser distance, and for rapid exposure, a very small tube at a very short distance is the best. The smallest tubes experimented with have been about one inch in diameter and with about two inches between electrodes, and with thin glass walls. A small tube requires a small e. m. f., so that tubes can be made to suit almost any induction coil.

7. For a given thickness of glass wall, German glass appears to give better results than lead glass. The German glass employed gives a yellowish fluorescence, while lead glass gives a greenish fluorescence. These glasses phosphoresce visibly for at least ten minutes after the cessation of discharges through the tubes. A particular quality of Scotch boiler water-gauge glass gives apparently equally good photographic results, but does not appreciably phosphoresce after the cessation of the current. The residual phosphorescence has not yet been found to produce a visible photographic image. All phosphorescence yet observed is pale white, whatever the color of the preceding flourescence under excitation.

8. The form of tube arrived at by a gradual process of selection is shown in Fig. 2. The length is about three times

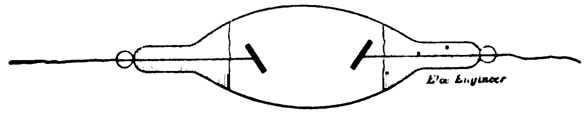

FIG. 2.

the diameter. This tube is made in various sizes. When the glass walls are made thin for producing the best photographic effect a spark is apt to pierce the wall and destroy the vacuum. Partly on this account, tinfoil caps are placed over the extremities of the tube, as indicated by the shaded areas in the sketch. These tinfoil caps are in connection with the electrodes and are cemented to the external surface of the tube by shellac.

9. It was found by repeated trials with many tubes that the fluorescent and photographic power of all the tubes without caps was greatly increased, roughly doubled, in fact, by bringing two metallic discs connected with the respective electrodes to the opposite points, as represented in Fig. 3. The supposition is that the tubes then become at once an ordinary and an electrodeless tube combined. The metallic caps above mentioned were the outcome of these experiments, and not only have all these capped tubes remained unperforated, but their fluorescent and photographic powers have been enchanced by the caps.

The caps serve three purposes: (a) To stop piercing by permitting excessive sparking to escape over the external surface. (b) To increase photographic and fluorescent power. (c) To prevent undue heating of internal electrodes and a consequent change of vacuum.

10. The exciting apparatus consists of a large Ruhmkorff coil capable of giving a 12-inch spark, although such a length of spark is rarely required.

The coil is usually excited from a 120-volt continuous-current circuit through a lamp bank of from eight to twenty 16-candle-power incandescent lamps arranged in parallel, with rapidly rotating wheel interrupter, driven by a small motor. About 400 interruptions are made per second, and the duration of closure in the circuit is twice that of opening. An air blast is directed upon the spark over the periphery of the interrupting wheel, through a fine nozzle. This tends to produce a sudden breaking of the circuit. It has been found that greatly improved results have followed the removal of the usual condenser and the substitution of the airblast. The resulting secondary e. m. f. is almost symmetrical like an alternating e. m.

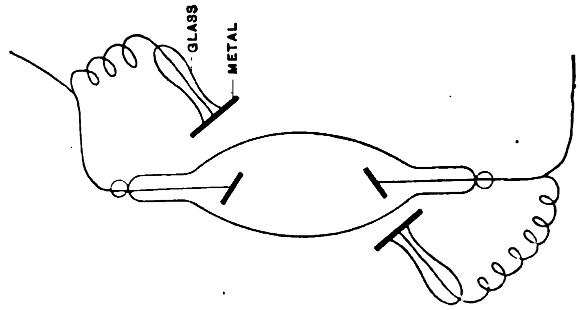

FIG. 3.

f., and the two electrodes in the tube are apparently equally active. The secondary terminals of the induction coil are led directly to the vacuum tube. If the airblast is removed and the condenser substituted, the fluorescent and photographic power of the tube is greatly diminished. The coil is sometimes excited directly through an interrupter from a battery of storage cells.

We believe that these observations of Mr. Edison cannot fail to be valuable to many practical workers with Röntgen rays. We hope to communicate further experimental results at some future time.

DO ORDINARY ILLUMINANTS GIVE OUT X-RAYS?

BY R. K. DUNCAN.

IT has been discovered by several investigators that a Welsbach burner or even an ordinary paraffin flame may be made to affect a covered sensitive plate and to give a shadow picture.

With the object of ascertaining whether this action was due to Röntgen rays, the writer made the following experiments:

1. We first obtained a shadow picture of a coin by placing both coin and plate in a carefully covered plate holder and exposing to the action of a Welsbach burner for seven hours at a distance of five inches. The result was a fairly good shadow picture. It was then apparent that if it took seven hours to obtain a picture from a Welsbach having a glass chimney over the incandescent mantle, it should take much less time if aluminum displaced the glass as a chimney, providing that the effect was due to X-rays, to the action of which aluminum is quite transparent.

2. A second experiment was made precisely similar to the first in time and method, except that aluminum was substituted for glass. After development, no image whatever was found upon the plates.

3. A third experiment similar to the second was tried and verified. This seems to dispose, then, of the idea that the effect is due to X-rays.

4. A fourth experiment was carried out with acetylene as the illuminant. A coin inside a watch glass was placed within a carefully covered plate holder and exposed for two hours to the action of two acetylene flames. After development an image of not only the coin, but the watch glass also, was found upon the plate, while a key wrapped up in aluminum gave nothing whatever.

Now, if the plate holder had been exposed to the action of X-rays from a Crookes tube we should have had a shadow of the watch glass without the case and a picture of the key in the aluminum.

The conclusion, therefore, which the writer draws from these experiments is that shadow pictures obtained from ordinary illuminants are not due to the action of X-rays. A fifth experiment shows that if the plate holder be placed within three inches of the Welsbach, so that it becomes hot, a very well defined shadow may be obtained in forty minutes. One may suspect, therefore, that the entire action is due to heat rays, or leakage of light through the cover of the sensitive plate.

ON RADIANT MATTER.—IV.

BY WILLIAM CROOKES, F. R. S.

IT is of great interest to ascertain whether the law governing the magnetic deflection of the trajectory of radiant matter is the same as has been found to hold good at a lower vacuum. The experiments just described were made with a very high vacuum. Fig. 16 represents a tube with a low vacuum. . When the induction spark is turned on, it passes as a narrow line of violet light joining the two poles. Underneath is a powerful electromagnet. On making contact with the magnet, the line of light dips in the center towards the magnet. On reversing the poles, the line is driven up to the top of the tube. We notice the difference between the two phenomena. Here the action is temporary. The dip takes place under the magnetic influence; the line of discharge then rises and pursues its path to the positive pole. In the high exhaustion, however, after the stream of radiant matter had dipped to the magnet, it did not recover itself, but continued its path in the altered direction.

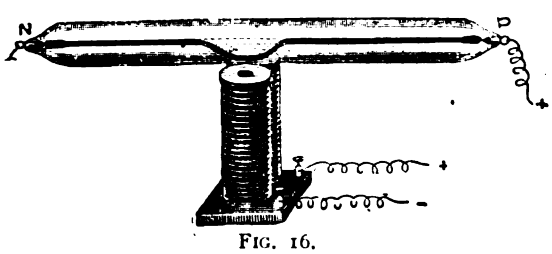

FIG. 16.

By means of the little wheel (Fig. 17) skillfully constructed by Mr. Gimingham, Mr. Crookes was able to show the magnetic deflection in the electric lantern. The negative pole (a, b) is in the form of a very shallow cup. In front of the cup is a mica screen (c, d), wide enough to intercept the radiant matter coming from the negative pole. Behind this screen is a mica wheel (e, f) with a series of vanes, making a sort of paddle wheel. So arranged, the molecular rays from the pole a b will be cut off from the wheel, and will not produce any movement. A magnet, g, was now put over the tube, so as to deflect the stream over or under the obstacle c d, and the result was rapid motion in one or the other direction, according to the way the magnet was turned. The image of the apparatus was thrown on the screen. The spiral lines painted on the wheel showed which way it turned. The magnet was arranged to draw the molecular stream so as to beat against the upper vanes, and the wheel revolved rapidly as if it were an overshot waterwheel. On turning the magnet so as to drive the radiant matter underneath, the wheel slackened speed, stopped, and then began to rotate the other way, like an undershot water wheel. This reversal can be repeated as often as the position of the magnet is reversed.

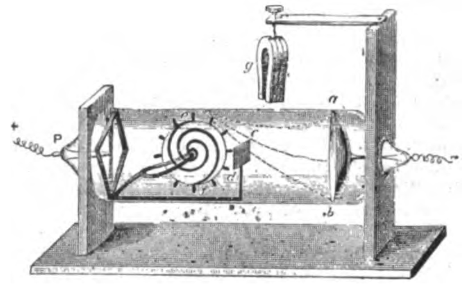

FIG. 17.

We have mentioned that the molecules of the radiant matter discharged from the negative pole are negatively electrified. It is probable that their velocity is owing to the mutual repulsion between the similarly electrified pole and the molecules. In less high vacua, such as that shown in Fig. 16, the discharge passes from one pole to another, carrying an electric current as if it were a flexible wire. Now it is of great interest to ascertain if the stream of radiant matter from the negative pole also carries a current. Fig. 18 is an apparatus which decides the question at once. The tube contains two negative terminals (a, b) close together at one end, and one positive terminal (c) at the other. This enables two streams of radiant matter to be sent side by side along the phosphorescent screen, or by disconnecting one negative pole, only one stream.

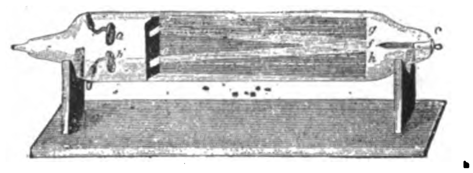

FIG. 18.

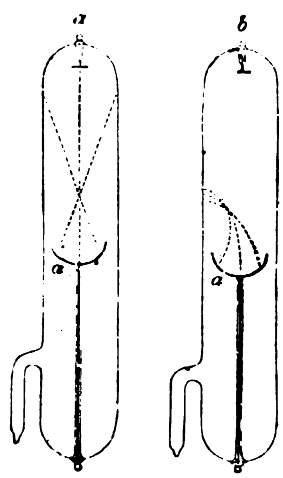

FIGS. 19 AND 20.

If the streams of radiant matter carry an electric current, they will act like two parallel conducting wires and attract one another; but if they are simply built up of negatively electrified molecules, they will repel each other.

The upper negative pole (a) was first connected with the coil, and the ray was seen shooting along the line d, f. The

lower negative pole (b) was then brought into play, and another line (e h) darted along the screen. Instantly the first line sprung up from its first position, d f, to d g,, showing that it was repelled, and the lower ray was also deflected downwards; therefore the two parallel streams of radiant matter exerted mutual repulsion, acting not like current carriers, but merely as similarly electrified bodies.

Another property of radiant matter is that the glass gets very warm where the green phosphorescence is strongest. The molecular focus on the tube (Fig. 8) is intensely hot.

An apparatus was exhibited by which this heat at the focus was made visible to the audience.

A small tube (Fig. 19) was prepareu with a cup-shaped negative pole. This cup projects the rays to a focus in the middle of the tube. At the side of the tube is a small electromagnet, which can be set in action by touching a key, and the focus is then drawn to the side of the glass tube (Fig. 20). To show the first action of the heat, the tube was coated with wax. The apparatus was put in front of the electric lantern, and a magnified image of the tube was thrown on the screen (Fig. 21). The coil was set to work, and the focus of molecular rays was projected along the tube. The magnetism was turned on, and the focus drawn to the side of the glass. The first thing seen was a small circular patch melted in the coating of wax. The glass soon began to disintegrate, cracks shooting starwise from the center of heat. The glass softened, next the atmospheric pressure forced it in, and then it melted. A hole (e) was perforated in the middle, the air rushed in, and the experiment was at an end.

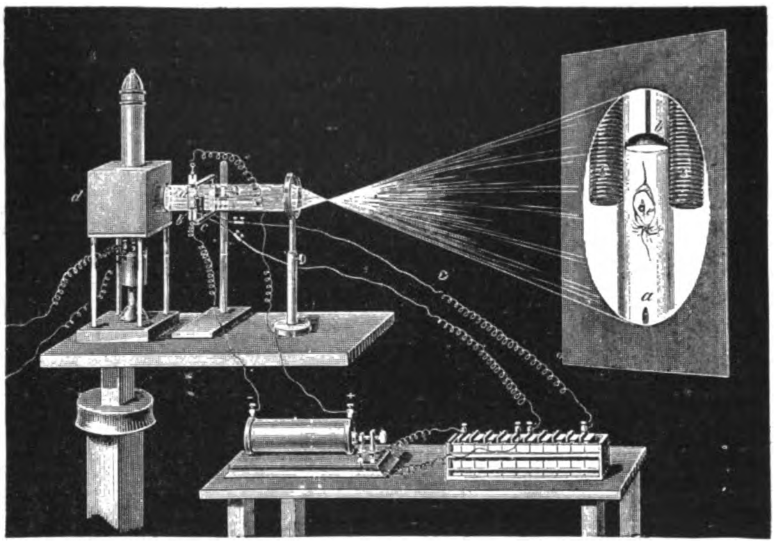

FIG. 21.

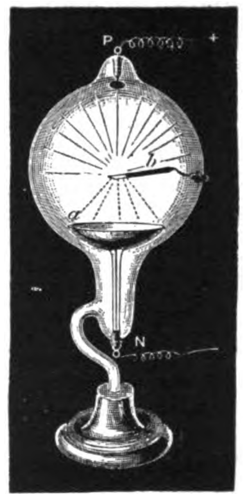

FIG. 22.

We can render this focal heat more evident if we allow it to play on a piece of metal. The bulb (Fig. 22) is furnished with a legative pole in the form of a cup. The focus of heat was deflected just as was the luminous focus in platinum (b) supported in the center of the bulb.

The induction-coil was first slightly turned on so as not to bring out its full power. The focus played on the metal, raising it to a white heat. By bringing a small magnet near, the focus of heat was deflected just as was the luminous focus in the other tube. By shifting the magnet the focus can be driven up and down, or drawn completely away from the metal, so as to leave it non-luminous. On withdrawing the magnet so as to let the molecules have full play again, the metal became white-hot. On increasing the intensity of the spark, the iridio-platinum glowed with almost insupportable brilliancy, and at last melted.

RED GLASS.—Photometrists and others interested in optical research will be glad to know that the firm of Putzler Bros., of Penzig, in Germany, have succeeded in making red pot glass, which is very clear and bright, but is opaque to the whole of the blue side of the spectrum, down to the line of the wave length 628. There has hitherto often been trouble in obtaining good samples of red glass for optical testing work and for obtaining non-actinic illumination.

STUDIES IN HYDRO-CARBON FLAMES—III.

BY DR. W. H. BIRCHMORE.

IT seems quite probable that the extra academic discussion of the nature and action of chemical rays which has begun since the announcement of the experiments of Professor Röntgen will bring about the diffusion of knowledge as to the actinic character of the Bunsen flame, but it has already shown a tendency to limit the field of inquiry.

The Bunsen flame is known of all men; it is a hydro-carbon-gas flame maintained at the most intense possible heat, which heat is limited only by the conditions of supply. This Bunsen flame is usually spoken of as being "faintly luminous," it is commonly called blue, but the color is well known to vary with the pressure and the amount of gas admitted to the burner. Any number of explanations of this "blue color" have been offered, some of them rather far-fetched, but few, if any, discussions of this flame have mentioned that the "blue flame" is not so hot by much as the "lavender" one. This lavender flame is a strictly neutral one, the spectrum is not continuous, but the gas and air must be so nicely balanced that the least possible derangement of the relation between them will precipitate the carbon and produce a continuous spectrum.[1]

THE SPECTRUM OF THE BUNSEN FLAME.—The spectrum of the Bunsen flame varies with every change in the composition of the hydro-carbon burned; not that there are any characteristic spectra in the sense that such belong to nickel, iron, sodium and copper, but the Bunsen flame from a lamp burning alcohol has not the same spectrum as that burning common illuminating gas, but has one which differs from the other in many suggestive ways.

The spectra seem to be a combination of the spectra of carbon at different temperatures, absorption spectra of various sorts, and the spectra of hydro-carbon and air gases, such as are produced under diminished pressure by electrical stress.

Notwithstanding the immense number of individual spectra, there are but three type forms, and these may be parted each from the other, not easily, but by reasonable effort, and these type form differ much in their temperature and actinic efficiency. These spectra may be called: (a) The phosphorescent spectrum, with bright lines. (b) The continuous spectrum, without carbon precipitation. (c) The continuous spectrum, with carbon precipitation.

The first of these is the one usually intended when the Bunsen burner spectrum is spoken of. It is a wide band which may be said to begin at the edge of the green, extend across the blue and enter the violet.[2]

[1]Technically a flame is said to be neutral when it is in just the balanced state described, if the oxygen is in excess it is called an acid flame, if the carbon is in excess it is called a reducing one.

[2]As it is probable that most of the spectroscopes to which my readers have access are those of small dispersion, the description of the spectrum given here is that of the one displayed by a single prism instrument, dispersion 12°, of the Kirchhof and Bunsen pattern, usually called the "large model," made in Geneva and sold by J. W. Queen & Co. The map of the spectrum referred to is the one from Schellen and is to be found in the front of Ganot's "Physics" and many books on chemistry and astronomy.

This band spectrum is not continuous, but has spaces in which the light is wanting, and it is unsteady. While under observation it will be seen to move, now in one direction and now in another. Against this band are projected bright lines.

When oil-enriched water gas is the fuel these lines may be described with sufficient exactness as a green, blue, and a violet line. These lines give a character to the flame and will always arrest the attention of any one examining.

If now the pressure of the gas is increased considerably a

FIG. 1.—PHOTOGRAPH BY BUNSEN BURNER, NON-LUMINOUS FLAME.
(Copyright, 1896, by W. H. Birchmore.)

continuous spectrum makes its appearance. Beginning in the yellow at a mid-distance between D and E, it extends through the entire visible spectrum, and with suitable precaution and apparatus it can be demonstrated far beyond it. The previously mentioned lines are still visible and in addition a line between G and H, which, when present is only less intense than the green line, but this line is unsteady, flashing into intense brilliancy and fading away as suddenly as it appears.

If the gas pressure be increased so that the supply of air aspirated just equals the consumption demand of the gas a new order of phenomena begins.

Up to this point the spectrum has been that of an incandescent gas, under pressure, of course, but now if the gas is in the least excess the spectrum of an incandescent solid is made evident; the bright lines are still there, however, and they are proportionately just as vivid as before. If now the supplies of gas and air are carefully manipulated and the "solid spectrum" be suppressed, and the yellow of the gas spectrum be made equal to the yellow of the same wave length from the sun, a number of differences can be distinguished.

There being no red in the gas spectrum, the solar red as

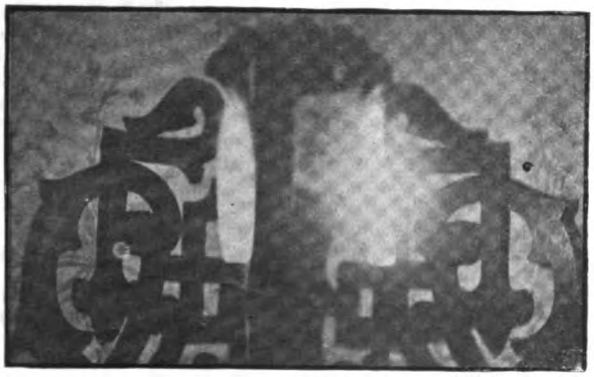

FIG. 2.—PHOTOGRAPH OF BUNSEN BURNERS, ONE LUMINOUS, OTHER NON-LUMINOUS.
(Copyright, 1896, by W. H. Birchmore.)

compared with the red of the gas spectrum is infinite, but when compared by suitable means it is apparent that the violet of the gas spectrum is vastly greater than that of the sun. Using a Bunsen photometer with a suitable screen, and proper precautions, the sun light may be compared directly with that of this gas flame. Under these conditions the sun light shows bright orange, almost red on a violet ground.

ACTINIC EFFECT.—Still more remarkable is the fact that candle-power for candle-power, the Bunsen burner radiation has a much greater photographic efficiency than has the sunlight. The luminous radiation of the particular Bunsen flame with which the photograph, Fig. 1, was taken, was about 0.003 of a candle equivalent, while its actinic effect appears to have been between 112 and 125 candle equivalent. This statement is near enough for my present purpose, and it is accurate within an error of 2 per cent., and may be less. I have

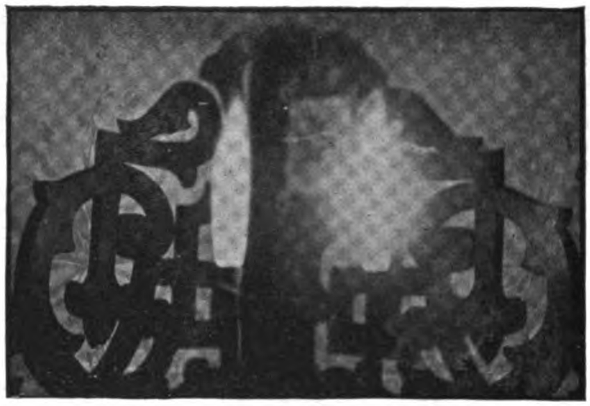

FIG. 3.—PHOTOGRAPH OF BUNSEN BURNERS, ONE LUMINOUS, OTHER NON-LUMINOUS.
(Copyright, 1896, by W. H. Birchmore.)

as yet made no direct efficiency measurements, have only calculated them from other data and it may appear that the actinic efficiency is even greater than this. If the above statement is reduced to a single proportion it makes the actinic efficiency of the Bunsen flame 40,000 times its luminous efficiency at the distance of ten feet.

The essential difference in the photographic action of a Bunsen flame and that of a candle is well shown by the photographs of the two flames side by side in Figs. 2 to 5. These two flames differ in no respect except that one is a Bunsen flame and the other is not. The burner with the wire tied about it is a Bunsen burner, burning with a Bunsen flame. The other is a Bunsen burner identical in every respect, gas supply from the top and all, except that the air is turned off so that it burns with a "candle flame." It has all the characteristics of a candle flame, produces the same electrical phenomena (these will be discussed in another chapter) and it produces a normal radiation.

THE HALO.—Attention is particularly desired for the halo which is seen to surround the central portion of this flame, and which is wanting about the Bunsen.

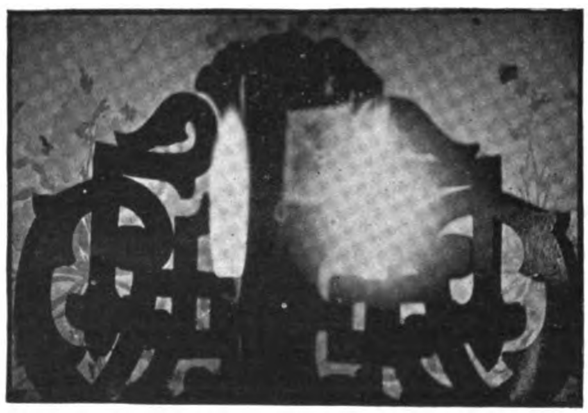

FIG. 4.—PHOTOGRAPH OF BUNSEN BURNERS, ONE LUMINOUS, OTHER NON-LUMINOUS.
(Copyright, 1896, by W. H. Birchmore.)

The halo is shown in Fig. 2 after an exposure of 20 seconds, and in Fig. 5 after an exposure of 120 seconds. I have a variety of plates between these two, but they only serve to emphasize the facts shown in these. The particular points of interest about this halo are: (a) The fact that it exists at all. (b) The fact that the Bunsen flame has none. (c) The fact that it belongs to the area of maximum luminosity. (d) The

fact that it is an invariable accompaniment of the continuous spectrum.

There is one common method of distinguishing between the stars and planets known to every one who interests himself at all in the notions of men uncorrupted by "college" training falsely so called. The cowboy on the plains or the tracker in Canada will alike point out to you the planets by the lack of twinkle. This "sparkle"—twinkle is the same word—of a star is the phenomenon we are studying when we study the halo of this flame. The disappearance of the twinkle and the star's appearance as a point of light, when examined by a telescope, has led to the belief that it was a subjective phenomenon. Lamps are seen to twinkle in a cold, clear night if at a distance from the observer, and when they are examined by a telescope this twinkle disappears. But it must be something real or the camera would not record it. The density and extent are known to bear a definite relation to the time of exposure, and the shape has to do with the flame only.

Examination of Fig. 2 shows that this halo is less dense on the side towards the other flame, and this inequality of density is seen in every one of the pictures which I have taken; the matter forming the cloud, be it what it may, is so acted on by the force set in motion in the other flame focus that it is repelled by it.

The flame of the Bunsen burner burning non-luminous never has this halo. But let the flame become luminous for never

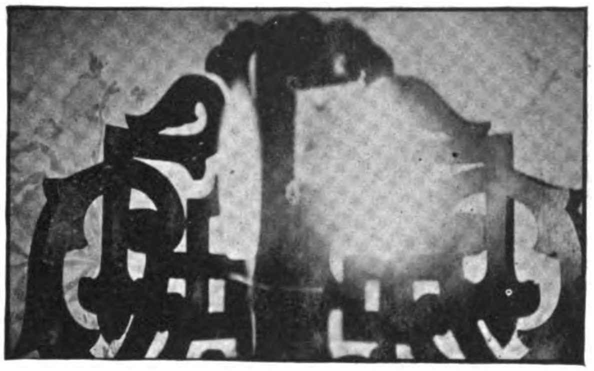

FIG. 5.—PHOTOGRAPH OF BUNSEN BURNERS, ONE LUMINOUS, OTHER NON-LUMINOUS.

(*Copyright, 1896, by W. H. Birchmore.*)

so short a time, let the spectroscope show even for a second the continuous spectrum of a solid, just so sure the camera will show the halo. I have made a large number of pictures of the Bunsen flames under various spectral conditions, and I have never found that the halo appears about a flame which has not shown a continuous spectrum at some time in its life, and I have never found it wanting about a flame which has shown such spectrum. This total absence of the halo around the Bunsen flame, its invariable presence about the luminous one, its greater density on the side away from the fellow burner, are phenomena invariably present under the given conditions. It is still further peculiar that the basis of the two flames are both incandescent gas, the spectra are both discontinuous, as if the gas was heating to precipitate its carbon atoms which, leaving the hydrogen, were either to fall into the grasp of oxygen atoms and burn to gases of combustion, or to grasp each other and go whirling off into space in rings of six atoms. In other words, around each luminous flame a little nebula of carbon exists. Is the combustion center of each flame surrounded by unburnt and unburning molecules of carbon, held near the flame by currents of air yet able to fly away from the center? It seems hardly likely that the radiant energy of the flame can account for all of this disturbance, and yet it must be one of the active factors.

The confined area considered in relation to the length of the flame is peculiar. The resolute refusal to show the center of radiation photographically and the influence of the time of exposure are also suggestive. If the halo were a continuous and persistent radiation then the strength would depend on the life of the flame and it would grow larger and larger, and if two exposures of the same duration are made one at three minutes after the flame begins, and the other at thirty minutes, it is plain that the flame with thirty minutes' life should have ten times as dense a halo as the one from that with a life of three minutes, if the action on the plate were due to the size of the halo. On the other hand, if the halo is of equal and very slight density throughout the flame life, or of increasing density, but of more feeble action from center to edge, the size and relations will depend on the time of exposure.

As was noted, the plane of the halo-equator coincides with the plane at right angles to the axis of the flame. Were this true of the zodiacal light it would present a startling analogy, and one cannot but wonder if the theory that this cosmic halo is produced by the sun as it shines on cosmic dust is true, and that this halo is caused by light shining on the dust in the room. But if it were chemical, actinic light should produce it, and this should come from the Bunsen, and as the disturbance in air dust by the Bunsen is greater, as well as its actinic action, it follows that the pictures of the halo should be larger and more dense.

I think, therefore, that the proposition that it is caused by the precipitated carbon has locus standi, and I invite the attention of students to it as an interesting problem. I think this is still further proved by the continuous spectrum association previously mentioned.

Some time ago I drew attention to the number of classes of rays of the same wave length given off by heated carbon, and stated that, as evidenced by carbon heated by the current, there were at last two kinds making themselves evident by photographs which had no direct action on the eye in producing color sensations or even light sensations. Somewhat similar action appears in reference to these flames. The actinic rays given off by the luminous and non-luminous flames produce substantially the same results, differing only in degree, when reflected from the surrounding objects, but when photographed directly, many divergent phenomena are seen. There is a notable difference, however, when the rays of a luminous flame separated by prismatic action are thrown on a phosphorescent screen. These influences of heated carbon, be they what they may, cease the instant a discontinuous spectrum appears. From these photographs it seems evident that the reverse is true, and that the instant hot carbon is precipitated from a gas a series of waves of some sort are started which it is not possible to produce by the action of heated gases at all.

ARE ROENTGEN RAYS LONGITUDINAL VIBRATIONS?

Professor J. J. Thomson has investigated the question of longitudinal vibrations in connection with the recent discoveries. In a paper read before the Cambridge Philosophical Society he discussed the theory of longitudinal waves from the the point of view of the electro-magnetic theory of light, and showed that on that theory longitudinal waves can exist (1) in a medium containing moving charged ions; (2) in any medium, provided the wave-length is so small as to be compared with molecular dimensions, and the ether in the medium is in motion. It was shown that it follows from the equations of the electro-magnetic field that the ether is set in motion in a varying electric field. These short waves would not be refracted, but in this respect they do not differ from transverse waves which on the electro-magnetic theory would not be refracted if the wave-length were comparable with molecular distances. The properties of the longitudinal waves were developed in the paper. Professor Thompson exhibited a number of photographs which had been taken at the Cavendish Laboratory by Professor Röntgen's method, and experiments made on the Röntgen rays were described. In one of these experiments the photographic plate was placed inside the vacuum tube so as to intercept the rays between the cathode and the walls of the tube; in this case the plate was not affected, showing that the fluorescence of the glass is necessary for the production of these rays. Other experiments were made to see if they could be excited by fluorescence without a cathode; the ring discharge was produced in bulbs, and caused a vivid phosphorescence; a plate protected by cardboard when exposed to the bulb for an hour was not affected, nor was any greater effect produced when the bulb was filled with a gas such as oxygen, which phosphoresces under the discharge. It thus appears that both a cathode and a phosphorescent substance are required for the production of these rays, and that one without the other is inoperative. A series of experiments were made by taking photographs through tourmaline plates, (1) with their axes parallel, (2) with their axes crossed; it was hoped by this method to get some evidence as to whether the rays were longitudinal or transverse. A considerable number of photographs were taken in this way, but no difference could be detected in the obstruction offered to the rays by the tourmaline plates in the two cases. Another method of investigating the same question was described, based on Elster and Geitel's discovery of the influence of the plane of polarization of light on its power to discharge electricity from a metallic surface. The experiments, which were not concluded until the day after the meeting of the society, show that these rays exert the most

powerful effect in discharging electricity whether positive or negative, from an insulated electrified metal plate exposed to their influence. A bulb separated from the charged plate by a board three-quarters of an inch thick covered with several layers of tinfoil exerted a most powerful effect, and it was not until the thickness of the metal between the bulb and the electrified plate was nearly a quarter of an inch that the effect ceased to be perceptible. The electrified plate is a much more delicate detector of these rays than the photographic one, and is more suitable when measurements are required. These results, though by no means conclusive, are in favor of the vibrations being longitudinal.

THE DE LAVAL TURBINE AND DESROZIERS DYNAMO IN THE EDISON STATIONS, NEW YORK.

IN the article describing the stations and work of the Edison Electric Illuminating Company, of New York, in "The Electrical Engineer" of Jan. 8, we noted the contemplated installation in the 12th street station of that company of a 300-horse-power DeLaval steam turbine, coupled direct to a Desroziers dynamo, both machines being manufactured by the Maison Breguet, of Paris.

The DeLaval turbine has been described in "The Electrical Engineer," but in view of this first instance of its application to electric central station work in this couuntry, it may be well to recall the salient features of that extremely interesting engine. The combination of turbine in dynamo is shown in perspective on this page, while Figs. 2, 3 and 4 show details which will explain its operation.

The principle of the DeLaval turbine is exactly similar to that of the Euler water turbine. It is so arranged that the steam only attains momentum when it reaches the turbine wheel. The expansion of steam takes place in diverging conical nozzles, shown in detail in Fig. 2. The smallest sectional area determines the quantity of steam which passes through a nozzle, and the proportion between the areas at each end of the nozzle determines the velocity of steam. If the end of the nozzle is too small, the steam is not quite discharged, and if it is too large the speed is too small. As the steam has lost its pressure when it gets into the buckets of the turbine wheel, this wheel does not require to be tight near the point of arrival of the steam and this is one of the great advantages of the DeLaval steam turbine.

As in the case of water turbines, to obtain the greatest efficiency the disc must run at a speed about half that of the steam. There were many difficulties to overcome to reach such speeds. However carefully the turbine may be manufactured it is impossible, on account of non-homogeneity of materials, to get the center of gravity exactly on the geometrical axis of revolution. Dr. DeLaval finally conceived the bold idea of providing the turbine with a flexible shaft. This flexible shaft allows the turbine to adjust itself and revolve around its true center of gravity while the shaft describes a surface of revolution. At one end the shaft is povided with a ball bearing, G, Fig. 4, to allow it to adust itself. On the shaft of the disc is a pinion, T, Fig. 3, engaging in one or two gear wheels, E, of ten times their diameter, to reduce the speed.

The governor is a centrifugal one, the rings being movable on knife edges with the least possible friction. When the speed becomes too high the weights diverge, their inner parts push a pin, which pin causes the cut-off of steam by the valve S.

The practical advantages which characterize the steam turbine are simplicity of fitting, small frictional resistance, small weight and absolute regularity of speed. The consumption of steam in these turbines is nearly the same as those of condensing compound engines. Numerous tests made in London, France and Belgium have shown that a 75-horse-power turbine requires 20.2 lbs. of steam per horse-power hour, with a boiler pressure of 140 lbs. A 100-horse-power turbine requires 19.1 lbs. of steam per horse-power hour, with 113 lbs. boiler pressure. A 200-horse-power running half load with 70 lbs. boiler pressure required 19.5 lbs. of steam per horse-power hour. A 300-horse-power with -±1 lbs. at the boiler requires only 16.5 lbs. of steam per horse-power hour.

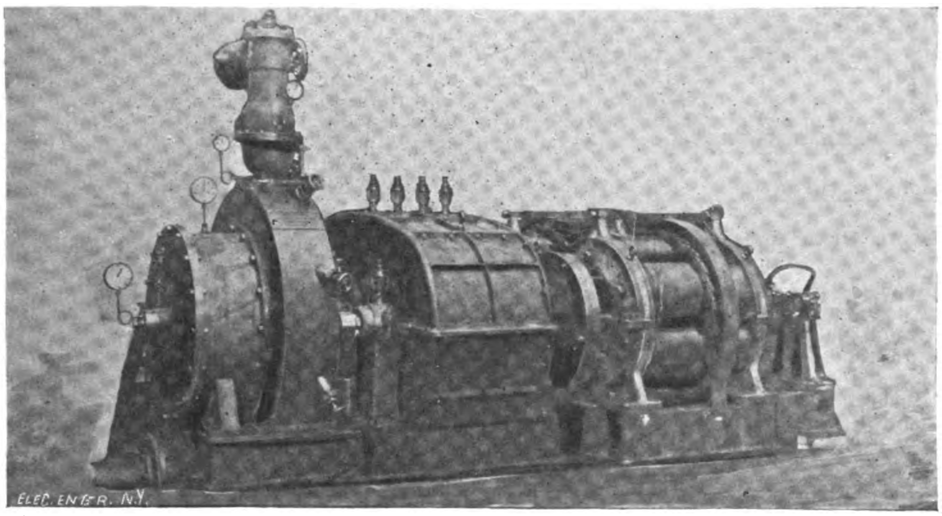

FIG. 1.—DE LAVAL STEAM TURBINE AND DESROZIERS DYNAMO, IN EDISON STATIONS, NEW YORK.

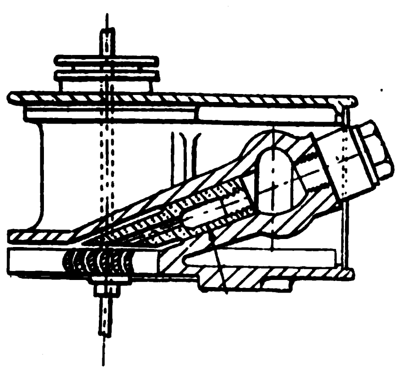

FIG. 2.—DETAIL OF NOZZLE AND DISC.

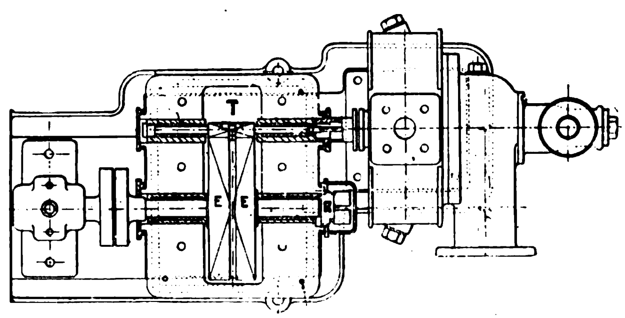

FIG. 3.—DE LAVAL STEAM TURBINE.—PLAN.

The Desroziers dynamo, to which the DeLaval turbine is coupled, is now so well known that no extended description is necessary. A full account of the construction of this machine

will be found in "The Electrical Engineer" of Sept. 20, 1893. We may recall to our readers, however, that the Desroziers dynamo is a multipolar disc machine, the armature conductors being wound on bare cardboard discs. Owing to the absence of iron in the construction, Foucault currents are entirely eliminated, and thus the main cause of heating in the armature is removed. Added to this is the weak reaction on the field, which gives a smooth characteristic curve and a constant efficiency, exceeding in the 100-horse-power machines, 93 per cent. Owing to the absence of iron in the armature, also, the weight of the machine is greatly reduced. Thus, at normal speeds the machines weigh only from 55 to 65 pounds per horse-power of output, and one pound of copper produces 160 watts.

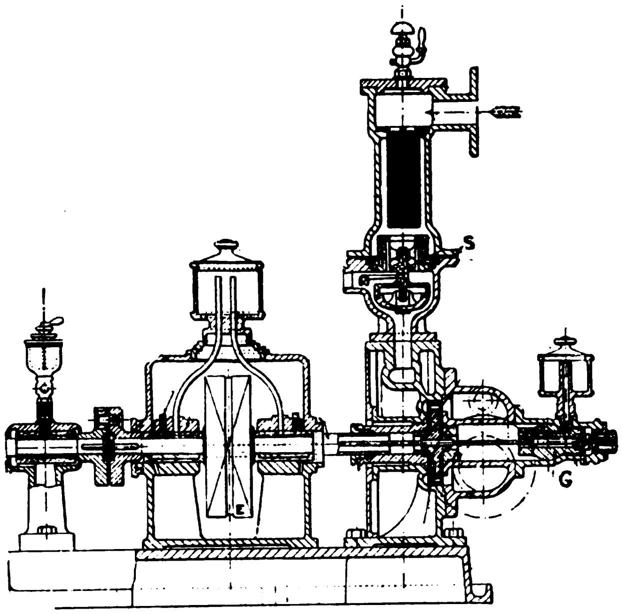

Fig. 4.—De Laval Steam Turbine.—Section.

Two of these steam turbine combinations are now in shape for steam connection, one in the 12th street station and the other in the 39th street station of the Edison Company.

THE SOUTH NORWALK (CONN.) MUNICIPAL LIGHTING PLANT.

BY A. E. WINCHESTER, E. E.

This plant[1] was started Oct. 13, 1892, and has been in continuous successful operation ever since, as will be seen by the following comparison of yearly reports from which it will be seen that each successive year shows a marked improvement over the previous one:

Price paid to the original company for 81 lamps previous to Oct. 13, 1892, when the municipal plant was started, was per 800 c. p. lamp per night on moon schedule, dusk to 1 A. M., about .... 22c.

Cost per lamp averaging 1,400 c. p. per night for year ending Oct. 12, 1893, supplied from city plant, 90 lamps in use, 311 nights per year lighted; no lights on bright moonlight nights. Lighting time from dusk to 1:30 A. M., later when necessary, on special occasions all night; interest on bonds $22,500, at 4 per cent., and depreciation of apparatus at 2½ per cent. on $15,000, value included .... 20¾c.

Cost per lamp averaging 1,400 c. p. per night for year ending Oct. 12, 1894, supplied from city plant, 98 lamps in use, 309 nights per year lighted, no lights on bright moonlight nights; lighting time from dusk to 1:30 A. M., later when necessary, on special occasions all night; interest on bonds, $22,500, at 4 per cent. and depreciation of apparatus at 5 per cent. on $15,000, value included .... 19 2-10c.

Cost per lamp averaging 1,400 c. p. per night for year ending Oct. 12, 1895, supplied from city plant, 98 lamps in use, 317 nights per year; no lights on bright moonlight nights; lighting time from dusk to 1:30 A. M., later when necessary, on special occasions all night; interest on bonds, $22,500, at 4 per cent. and depreciation of apparatus at 5 per cent. on $15,633, value included .... 19c.

The Electric Light Commissioners are continually receiving requests from municipal governments from all parts of the United States and Canada for reports and information regarding the South Norwalk Electric Works, which, though a very small plant, has become widely known as an example of an unusually successful municipal electric light plant, so much so, that many experts, some of them skeptical, have visited it for the purpose of personal investigation as the station register, a book in which all guests are requested to place their names and addresses will show; but without exception all have expressed themselves as convinced of the plant's practical success, and have congratulated the city on its valuable possession, the economy of which they have attributed not only to high efficiency of apparatus, but to careful business management. The distribution of light is said to be unsurpassed by any of the larger cities of this country, it being possible to tell the time from a watch without difficulty at the darkest spot between any two lamps.

Some time ago the city voted to establish a commercial plant in connection with the present street lighting system, the revenue from which it is believed would in a large measure, if not entirely, defray the expenses of the entire plant, and make it self-sustaining, thus reducing the tax assessment to a considerable degree. An appointed committee, including the Board of Electric Light Commissioners, is now carefully investigating the subject, and will soon report to a city meeting the result of their efforts, which will include a plan embodying the latest ideas and improvements in the method of electric lighting. The concentration of the lighting district is such that the low tension direct current is deemed most suitable for all purposes and a storage battery outfit will be considered to take care of the day load, and the maximum night load, so that the generating plant will only operate during the evening, when it will work under full load throughout the run.

The intention is to make the plant a model of practicability and economy in every way, from which all electric light, heat and power required by the inhabitants of the city can be supplied at a reasonable rate, which will return a self-sustaining revenue, as does the present water works.

The very efficient operating force of the plant is composed of three men—Superintendent W. L. Bonnel, Engineer Wm. H. Mosher, Jr., and Lineman Edward Laidlaw—all experts of long experience, as is evidenced by the extremely low rate of running expenses, the neatness of the plant, and the careful and systematic manner in which it is operated.

The plant is in charge of three commissioners, who serve without salary.

[1]For a detailed description of this plant see "The Electrical Engineer," Jan. 30, 1895.

A LIGHTING PLANT WASHED OUT.

The recent storm in Manchester, N. H., and vicinity caused much damage. The most serious blow was at Kelley's Falls, where a part of the dam went out and the ice in the basin behind the dam broke up and went over. The Kelley's Falls Electric Light Works were almost wiped out of existence. Seven men, including Superintendent Whitney and Machine Expert W. R. Smith had close calls for their lives. The crash came unexpectedly. Smith was standing on the canal flume, which was swept into the stream. He floated down the river for a mile, being buffeted by cakes of ice, and reached the shore more dead than alive. The others were caught in the torrent and narrowly escaped with their lives.

The damage to the Kelley's Falls electric light plant is estimated at $50,000. Much of the machinery is in the river.

VIBRATION AND CONDUCTIVITY.

Signor Murani, in "L'Elettricita," describes experiments on the influences of vibration on the resistance of wires. To avoid the heating due to friction, the vibrations in a series of metallic wires were induced by an electromagnetic tuning-fork, wires of hardened iron, platinum, hard steel, hard copper, German silver, and manganin being tested, and in no case was any variation in the electric resistance detected by the most delicate methods. It is consequently concluded that the resistance of metallic wires is not altered by vibrations, all results to the contrary obtained by other observers notwithstanding.

THE CAMPBELL & ZELL COMPANY, through their agent, Mr. A. W. Weller, have sold to the New London (Conn.) Street Railway Company 500 horse-power of Zell water tube safety boilers.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—IV

BY

Wm Baxter Jr

THE data presented in the foregoing sustain the claim that the substitution of electricity for steam would effect a saving of 55 per cent. of the coal bill, and this would be 5.5 per cent. of the total operating expenses, the coal bill being 10 per cent. of the whole. A saving of 5½ per cent. of the total expenses is not a small matter by any means and a road would be justified in going to considerable expense to effect it.

This, however, is not all that can be saved of the 10 per cent. now required to cover cost of fuel. The saving so far shown only represents that due to difference in amount of coal consumed per unit of energy expended on the track. As will be shown later on, there are sources of loss in the operation of a road by steam that would not exist if electricity were the motive power, and the elimination of these losses would raise the saving in coal consumption considerably above 55 per cent.

The saving in coal alone, however, is not the all-important factor upon which hangs the future destiny of electricity in the steam railway field. There are other directions in which fully as great, if not a greater, saving can be made. This, however, is not all; electricity's claim for a hearing is not based wholly on the question of economy. The comfort and safety of the traveling public, as well as more rapid interurban transit, are paramount factors which must be considered in deciding upon the merits of a system, and in these respects it can be easily demonstrated that electricity is far ahead of steam.

Before going into a consideration of the questions of comfort, safety and greater speed, it will be well to point out briefly the various ways in which electricity can reduce the operating expenses other than the one already given.

In the first place, we have the very important fact that the electric motor does not depend upon the skill of the man who handles it for its efficiency, while the locomotive does. No matter what the intelligence of the motorman may be, the energy absorbed in doing a given amount of work with the same motor will always be the same. This is by no means the case with a locomotive. There are two ways by which the speed of a locomotive can be regulated, one by the movement of the link motion lever, and the other by opening and closing the throttle. If the link motion lever is used, the steam will be expanded in the cylinders and the highest efficiency obtained. By using the link motion the throw of the valve is shortened, in precisely the same way as it is in the various types of high-speed engines that have a single valve, the motion of which is regulated by the governor. Under these conditions the locomotive becomes a variable cut-off engine, and works at a high rate of efficiency. But when the throttle is used to regulate the speed, it becomes simply a slide valve engine, and uses a much greater amount of steam to do the same work. Therefore, the amount of coal consumed to do the work will depend upon the way in which the speed is regulated.

The amount of coal used to generate steam will further depend upon the skill and care of the fireman. It may not be supposed that the difference in coal consumption, due to the way in which the locomotive is handled, amounts to very much, but actual records show that it is as much as ten to fifteen pounds per train mile. This is one point in which steam is at a decided disadvantage when compared with electricity. It may be said that what is true of the locomotive is true of the engine in the power station of an electric system, but such is not the case. The engines regulate themselves by the action of the governor, and so far as the efficient use of steam is concerned, are no more dependent on the skill of the engineer than the motor is. As to the wastefulness of the fireman, it is not at all likely to be as great in the station as on the locomotive.

Another direction in which electricity has an advantage over steam is in the weight of locomotives required to haul a given load. A locomotive weighing, say, 60 tons, will have about 45 tons on the drivers, possibly 50 tons. The tender will weigh about 30 tons, and coal and water about 10 tons more. Therefore, out of 100 tons of engine, tender, coal, and water, from 45 to 50 tons only rests on the drivers. At slow speeds, the capacity of a locomotive depends, not on the amount of work the steam in the cylinders can do, but on the adhesion of the wheels to the track, or, in other words, on the weight on the drivers. As only half the weight rests on the drivers, the other half is useless, and is just so much dead weight that has to be hauled over the road to supply the motive power.

An electric locomotive of half the weight will do just as much work, at low speeds, because all the weight would be on the drivers. A locomotive not only has to exert enough energy to draw the train of cars behind it, but must also draw its own weight. It follows, therefore, that the lighter the locomotive the less power that will be required to draw the train. In high-speed passenger service, the weight of locomotive and tender is a very large portion of the entire weight of train. The Empire State Express train on the New York Central Railroad weighs on an average 340,000 pounds, while the engine, including tender, weighs 200,000 pounds, which is about 37 per cent. of the entire weight. This, it must be admitted, is an exceptional case, but in all high-speed work, the ratio of engine to train weight will not fall very far below this figure.

With local passenger trains this percentage will drop considerably, and will be still lower in freight trains, but, whatever it may be in any given case, it is evident that it would be lower with electric locomotives, from the fact that all the weight would be on the drivers. Any reduction that may be made in the total weight of train, by a reduction in the weight of motive power portion will represent just so much gain in favor of the electric system.

There is another direction in which a considerable saving in coal can be made, and that is in the operation of switching engines. This point has not heretofore received much attention in discussions on this subject. It no doubt has been considered of not enough importance to be considered as a factor in the general operating expenses of a road; but such is not the case. A few figures taken from the reports of a large number of roads will show its bearing on the subject.

Take, for example, the total of all the roads in the State of Ohio, Illinois, and New York. According to the reports the train mileage is as given in the following table:

Table 9.

Total Mileage in Ohio—Eighty-Seven Roads Reporting.

Total mileage of passenger trains	24,182,674
Total mileage of freight trains	32,901,611
Total mileage of mixed trains	912,925
Total	58,004,210
Total mileage of switching engines	14,935,541
Total mileage of construction engines	1,339,635
Total of switching and construction	16,275,176
Grand total	74,279,386

Percentage of switching and construction mileage of passenger, freight, and mixed equals 28 per cent. approximately.

Total Mileage in State of New York—One Hundred Roads Reporting.

Total passenger mileage	65,922,703
Total freight mileage	95,914,305
Total	161,837,008
Total all other mileage	42,809,169

Percentage of switching, etc., of passenger and freight equals 26 per cent. approximately.

Total Mileage in State of Illinois.

Total passenger mileage	29,235,262
Total freight mileage	37,801,675
Total	67,036,937
Total switching mileage	17,496,226
Total construction mileage	1,017,412
Total	18,513,638

Percentage of switching, etc., of passenger and freight mileage equals 27 per cent approximately.

If these figures, which are taken from the official reports, are correct, then the mileage of switching engines amounts on an average to about 27 per cent. of the revenue earning mileage. It is but fair to say, however, that a close inspection of the reports leads one to believe that the mileage of switching engines, as estimated, is possibly based upon the time the engines are in service, it being assumed that a unit of time represents a certain number of miles run. This conclusion is strengthened by the fact that the miles run per year by switching engines is in some cases greater than that of freight locomotives. Inasmuch as switching engines are most of the time standing on the track waiting for trains to be made up, and, when in motion, only go a short distance at a time, it is quite evident that the total distance covered in a year must be far below the average of engines in regular service.

A more accurate estimate of the relation between work done by switching and revenue-earning locomotives can be made by comparing the coal consumption in both cases, and also the number of engines used in each class of service. According to the Illinois State report, the total amount of coal consumed by all the locomotives in the State engaged in passenger and freight service for the year 1894 was 3,076,978 tons. The consumption by switching and construction engines was 596,-927 tons, of which 30,228 tons, or a trifle more than 5 per cent., is allotted to construction work. These figures show that the coal consumed by switching engines amounts to about 19 per cent. of that used by freight and passenger locomotives combined.

Taking the relation between the number of locomotives in service, we find that in the State of Ohio there are 1,252 passenger, 2,953 freight, and 899 switching engines. In Illinois there are 2,083 passenger, 4,797 freight, and 1,455 switching engines. Taking the sum of these two States we find that the number of locomotives in the passenger and freight service is 11,085, while those used for switching purposes amount to 2,354, or something over 17 per cent. of the entire equipment.

When we consider the character of work performed by switching engines it at once becomes evident that this is a field in which the saving that can be effected by electricity will be relatively very great. A little reflection will show that the coal consumption per horse-power in this class of work must be very high, because the engines are in motion only a small portion of the time, and then, in most cases, only run short distances. Sometimes an engine may be engaged for hours, hauling a few cars at a time, first in one direction and then in the other, in the process of making up trains. The actual work done in this kind of service is very small, and if reduced to an average for the entire time over which it is spread, would perhaps not amount to more than 25 or 30 horse-power continuous output. But, although the engine is only required to do work for a few minutes at a time with intervening periods of rest of more or less duration, the fire has to be kept bright and a full head of steam on so as to be ready to move at a moment's notice. It is plain to be seen that under such conditions more coal is consumed keeping the locomotive in readiness than that required to do the actual work.

Electric motors would do this kind of work at a very much higher efficiency than locomotives, for the very simple reason that no energy would be drawn from the power station except when the motors were in motion.

ELECTRIC TRACTION BY POLYPHASE CURRENTS.

What we believe to be the first application of polyphase currents directly to electric traction, says the London "Electrician," is now being made by Messrs. Brown, Boveri & Co., at Lugano, in Switzerland. At this place an electric railway is being equipped with polyphase plant, and will, it is hoped, shortly be ready to start work. Preliminary trials have already been made with successful results.

The power for this railway is derived from a waterfall, where a power house has been installed with a 300-horse-power turbine, driving two 150-horse-power three-phase alternators. The power is generated at 5,000 volts, and a portion of it is used by a chocolate factory near the power house. The three-phase generators are of a special type in which the only moving parts are the iron star-shaped pole cores. Both the field coils and the armatures are stationary.

Three-phase current for the railway is conveyed at 5,000 volts, overhead, over a distance of 12 kilometers (7½ miles) to Lugano, where it is transformed down to 400 volts by ordinary transformers. The power is there distributed to the cars by means of two aerial or trolley lines, the third conductor being supplied by the rails. Three-phase motors on the cars receive power through a double trolley-wheel apparatus; and a special form of controller is used when varying the speed or reversing the car. The motors are designed to give a normal speed of 15 kilometers (9⅜ miles) per hour.

The advantages which attend the use of polyphase currents for electric traction are, principally, in enabling power to be derived from a distant source, and in allowing the use of motors which require no commutator, collector, nor bare electrical conductor upon them. On the other hand, a double trolley line and the duplication of the trolley collector wheels are rendered necessary. Of the modifications in the controller which are involved, we cannot now speak particularly; though it seems probable that a more complicated construction than where the current is continuous would be essential, this need not, however, necessitate additional complexity in the manipulation of the controller. The use of two overhead conductors must also present a disadvantage from the increased risk of breakdown due to a telegraph or telephone wire falling across them.

A NEW METHOD OF TESTING RAIL BONDS.

THE beautiful "Gorge Road" at Niagara Falls was equipped with the plastic bond, which was applied when the road was built last August. Although Mr. J. K. Brooks, the superintendent of the road, never had the slightest trouble from a single joint, and although he had once a month removed angle plates and examined the bonds, always finding them in perfect condition, the president determined to have a test made of every bond on the line now operated from the Whirlpool Rapids to Lewiston.

With seven miles of track and rails 30 feet long, it was thought to be a difficult matter to get an accurate reading of the current and drop at each bond. But a novel method suggested by Mr. Harold P. Brown enabled the superintendent to complete the work in two hours. The test was a great triumph for the plastic bonds, since it showed that not a single bond was defective and that the drop on each joint with 100 amperes current was but 0.005 volt, or ⅛ that of a new copper bond 8 inches long and 0.42 of an inch in diameter.

Two large double truck cars were placed 20 feet apart and on their projecting bumpers was laid a strong wooden beam 21 feet long and 6 by 8 inches in section. This was firmly lashed in place with ropes; the drawbars were then joined together and a strain put on their springs with a block and tackle so as to take up any lost motion between the cars and the beam. This arrangement left just 28 feet between the rail contacts of the rear wheels of No. 1 car and the front wheels of No. 2 car.

These trucks were then connected by an insulated wire in which was interposed a very low reading voltmeter. A high reading voltmeter was placed between trolley and rail and an ammeter put in series with the motors. Then the motors of No. 1 car were started and brake set on No. 2 car until 100 amperes were required to run the cars at about 3 miles an hour. It is evident that as the train moved away from the power house, the low reading voltmeter would indicate the drop in pressure due to the resistance of the rails and joints between the cars.

The rail joints are placed in the center of the opposite rail, and therefore during a movement of 2 feet the rear truck of No. 1 car and front truck of No. 2 feet were on the same rail, while there was a joint between them on the other rail.

During the next 13 feet there was a joint in each rail. The consequent variation in the voltmeter's reading represented the increase of drop due to one joint. At its lower point, which would be held for about one-half a second, the reading represented the drop due to 28 feet of unbroken rail, in parallel with a similar length of rail having one joint and a pair of plastic bonds. For the next 3¼ seconds the reading would be higher since there was a joint in each rail. Knowing the drop per foot of rail with a given current, the readings were easily verified by calculating the total drop and comparing it with the indications of the high reading voltmeters on the car at the end of the line and at the power house.

This is believed to be the first time that a test has been made of each bond on an electric railway and the results are certainly remarkable. An interesting feature of the test was the performance of the Westinghouse motors, which pulled the two heavy cars up the hill at the Lewiston end with only 20 amperes.

JERSEY TROLLEY TO CONSOLIDATE.

The combination of all trolley companies of New Jersey, which has been under consideration for over a year, is practically completed, it is stated, and the incorporation may be recorded any day.

The proposition was definitely decided on at a recent meeting of representatives of the interests involved. Among those present at that time were: E. F. C. Young, president of the Consolidated Traction Company; David Young, the general manager, and Joseph Coult, the counsel of the Consolidated Traction; Frank Bergen, representing the Elizabeth lines controlled by John Kean; Gen. Bird W. Spencer, of the lines running through Bergen and Passaic counties; Garret A. Hobart, counsel of the Paterson lines; President Moore and Thomas C. Barr, of the Trenton lines; President Tierney, of the North Bergen Traction Company, of Hoboken; Edward Ambler Armstrong, counsel of the Camden corporations that conduct the street car systems in that city; Elias S. Ward, president of the South Orange line, and one of the promoters of the North Jersey Traction Company, and Andrew Radel, representing the New Brunswick system.

OPERATING EXPENSES OF ENGLISH ELECTRIC ROADS.

The recently published accounts of the Liverpool Overhead Railway and the City and South London Railway Companies, which have been recently noted in these columns, are quite worthy of a more detailed consideration than they usually receive. It is hardly necessary to point out that the only point of semblance between the two lines is the electrical propulsion. True, they have many characteristics in common which appertain to ordinary railway practice, but to illustrate the difference between running trains through underground tunnels, which are unaffected by climatic changes, and propelling trains on an overhead structure, subject to many changeable conditions, it is only necessary to refer to cost of maintenance of way, work, etc. For a train mileage of 321,417 the Liverpool line spent £3,619 in the latter half of 1895, while the City and South London with 227,350 train miles cost £462; it is true that the South London line is just about half the length of the Liverpool Overhead; but that would not account for the difference of eight times the cost. As a matter of fact, very considerable sums are spent by the Liverpool Company in operating swing bridges across the docks; the repairs of structure and opening bridges alone absorbing £1,240. Before proceeding further it would be as well to give a table setting forth the cost per train mile on the two lines for corresponding periods.

Cost Per Train Mile.

	City and South London Ry. 1894.	1895.	Lvpl O'head Railway. 1894.	1895.
Maintenance of way, works, etc..	.54	.48	1.99	2.68
Locomotive and generating power	6.02	6.0	3.23	3.64
Traffic expenses	5.95	5.85	5.07	4.94
General charges	1.73	1.71	1.52	1.53
	14.62	14.51	11.98	12.92

It will be seen that the cost of loco and generating power is very much less on the overhead than on the underground line. The sum spent in this department by the Liverpool line stands at £4,921, against £5,707 on the South London system. The lower cost per train mile is, of course, partly accounted for by the heavier train mileage on the overhead line, for certain charges under this heading would not be increased on the South London line if more trains were run. The principal sum is in connection with wages for working generating engines and motors, the difference between the two systems being only about £13. We may always expect coal to figure somewhat largely in running expenses of London lines, and it is doubtful whether they will ever be quite as low as at Liverpool, although it may be expected that there would be, occasionally, greater losses of power on an electric railway worked in the open. But all things considered, we may reasonably doubt whether an increased train mileage on the city line would have brought down the cost to anything like the favorable figure obtained at Liverpool. What we have said about the power expenses applies equally to "traffic expenses." This item on both lines is very much the same, and there would be probably a slight reduction in the case of the City Company if more trains were run. In justice to the company, however, it should be mentioned that a considerable amount is included in this item for hydraulic power for lifts.

It is not easy to discover the number of passengers carried per train mile on both lines, but the receipts are a little curious.

	1894.	1895.
Liverpool Overhead	18d.	22d.
City and South London	24d.	25d.

While the city line obtains a considerably higher sum per mile, the increase in receipts per train mile on the Liverpool system are most marked. It would be difficult to understand if the city company's receipts were not higher than those at Liverpool, for a comparison between the two neighborhoods would show that while the Liverpool Company traverse occasionally somewhat thinly populated districts, the South London line passes through densely populated neighborhoods; but, as we have often said before, the city line will not be worked to the best advantage until the line is extended much beyond its present limits.

Notwithstanding the fact that the total expenses of operating the Liverpool overhead line is 12.92d., the economical nature of electric propulsion is placed beyond a doubt. The cost of working the line will compare favorably with the best managed steam locomotive system. It is not easy, of course, to apply the figures to tramway practice, indeed, conditions are so absolutely foreign to what obtains in ordinary streets that it would be useless to make the attempt, but it is not too much to say that the figures relating to cost of generating power would form no bad argument for electric traction on ordinary tram lines.—London "Electrical Review."

THE WINTER'S EXPERIENCE ON THE LENOX AVE. CONDUIT ROAD, NEW YORK.

The underground road which the General Electric Company installed on Lenox avenue, New York, has emerged successfully from the tests to which the recent severe snowstorms have subjected it. During the violent snowstorm of the 11th of March, the operation of the road did not cease for an instant. The snow began to fall about 8 o'clock in the morning and the snow-sweeper was started out over the line, but before it could make the complete trip the sprocket wheels of the broom broke, and it was necessary to push the sweeper back into the barn for repairs. Not until 4 o'clock in the afternoon was it ready to go out on the tracks again. Meanwhile the service of the road was conducted without any stoppage, and the cars ran over the unswept tracks with no greater delay than would be ordinarily caused by considerable slipping of the car wheels on the snow-covered rails; it took about eight or ten minutes longer to make the trip.

At some points on the line the snow was swept by the wind into drifts, making it necessary for the motorman to back his car to get the necessary momentum to push his vehicle through the drifted snow. At 4 o'clock the snow-sweeper cleared the line of the snow and regular schedule time was again resumed.

About 8 o'clock the storm turned to sleet and hail and as it fell covered the rails with ice. Notwithstanding this, the cars ran under their usual headway.

On the Lexington avenue electric conduit road a gang of men swept the tracks and on this line the cars made schedule time while the bad weather prevailed. Throughout the duration of the storm no electrical trouble of any kind was developed either in the conduit or in the cars. The rolling stock of the electric conduit lines of the Metropolitan Traction Company is now undergoing a large increase. Equipment has been started on a number of new cars and they will be put into service as soon as they are ready.

LETTERS TO THE EDITOR.

AN EXPLANATION WANTED.

Kindly ask your readers as to their ideas concerning the following experiment:

If an incandescent lamp of 16 c. p. on a 110-volt circuit is screwed in its socket loosely, so that it does not light, but by gentle tap would light, be struck at the socket suddenly with a piece of wood, a glow of light is seen for about an instant similar to that of a phosphorescent glow? The glow is only visible at the base of the lamp. At one time it was so bright that it was visible in the sunlight. J. M.

New York.

SOCIETY AND CLUB NOTES.

NEW YORK ELECTRICAL SOCIETY.—ROENTGEN RAYS.

A meeting of the society will be held at Columbia College, Madison avenue, and 49th street, on Thursday, the 19th inst., at 8 P. M. Mr. Max Osterberg will lecture on "The Röntgen Ray; a Record of Experiment and Speculation." Mr. Osterberg will review carefully and thoroughly all the developments that have been made up to date in the investigation of the remarkable phenomena to which attention was first drawn by the interesting work of Professor Röntgen. The lecture will be supplemented by a display of apparatus used in photographing through opaque objects, and illustrated by lantern slides, and there will be shown various Crookes tubes, especially designed for this class of work. The meeting promises to be one of the most interesting and important held by the society, and that is saying a good deal.

UNDERWRITERS' RULES CONFERENCE.

As already announced, the conference under the auspices of the National Electric Light Association, of electrical, insurance and allied interests, looking to the adoption and enforcement of a national code of rules for electrical construction and operation, will be held this week, on Wednesday and Thursday, at the headquarters of the American Society of Mechanical Engineers, 12 W. 31st street. Its deliberations will be watched with much interest.

VOL. XXI. NEW YORK, MARCH 18, 1896. No. 411.

CONTENTS.

A TIME OF TRUCE.

WE print elsewhere in this issue the official statement of the terms upon which the compact so long and assiduously worked for has at last been arrived at between the General Electric and Westinghouse Companies. The lawyers have had their way for some years past, but just now the bankers are on top, and propose to see that some of the money which has hitherto been spent in litigation shall go in dividends, or at least in supporting the value of the stock by tangible assets and bank reserves. At least, this is the first superficial view of the situation, for it may prove that after all, having agreed to let each other alone, the two great companies may turn their legal artillery on the common outsiders. As things stand, the arrangement ought easily to save the two companies $500,000 a year in legal expenses, all told; and to that extent should be better able to pay dividends; but if the two Catholic powers should now combine to crush out the Protestant schismatics and heretics by a joint war of inquisition and extermination, more money than ever may be needed for belligerent purposes.

Broadly considered, the arrangement is sagacious and worthy of commendation. The electrical industries need peace, if but for a time. The cutting of prices; the uncertain value that has begun to attach to patents, whether sustained or not, and the demoralization of warfare, have brought about a state of things that no one desirous for the solid growth of electric light and power could regard with pleasure, or with anything but feelings of regret and anxiety. We believe both parties to be sincere in their desire for peace, and honest in their determination to maintain it. We would be glad also to know that the principles to which they now give limited application were accepted by them and others as worthy of adoption throughout, so that the revenues squandered in fighting might not only be conserved but increased by judicious agreement upon terms of royalty along many lines. During the great contest over the incandescent lamp, we ventured to urge a policy of conciliation which would have respected patents, protected prices, and brought prosperity. The victory that was won is perhaps the hollowest on record. It cost a magnificent fortune and there is absolutely not a cent to show for it.

Whether the General Electric Company can now rehabilitate itself financially remains to be seen. Its capitalization is enormous, and it owes not far short of 20 per cent. on its preferred stock. The common stock is quoted at prices around 40, but it is doubtful whether it would have any value under any proper plan of reorganization. One of the New York papers in discussing the theory that since the preferred stock sold at 71 and the common around 37, one of the two stocks was not at a normal price, says: "The price of the preferred stock carries cumulative dividends at 7 per cent. for over two years and a half, so that the stock was really selling around 53. Those who worried over the relative prices of the two stocks overlooked the fact that while the preferred stock cannot pay over 7 per cent. dividends, the amount of possible dividends on the common stock is unlimited." The idea of dividends being "unlimited" on General Electric common is nothing short of deliciously comic. The savings on litigation and labor, as well as the gains due to better prices, will have to be abnormally large before the dividends on the common can even be "limited."

As to the feasibility of a control by this new alliance of the vast domain of electric light and power, we have no belief in it whatever. Each attempt in that direction is a more gigantic failure than its predecessor. The fact is, there never was a time of better opportunity for free development in different directions. The very fact that the patents of Mr. Tesla constitute the main basis of the 37½ per cent. of the Westinghouse Company's part in the pool shows how rapidly times change. A few years ago, Mr. Tesla's name was known only to a few, and his work in power transmission is a recent development, the practical part of which all lies in the last three

or four years. If a newcomer can thus revolutionize a field of work so swiftly and so radically, it is in itself an evidence of further and far-reaching changes, perhaps by himself, most assuredly by somebody. The age of great inventions in electricity is not past; it has only just begun, and the whole drift of electrical work to-day is away from monopoly.

INVENTION IN ELECTRICAL DETAILS.

ONE cannot but feel that justice has been done by Judge Coxe in his decision, the text of which is printed in this issue, awarding due credit to Mr. Stieringer for his early work in the invention of the combination fixture and the insulating joint. A previous decision directed against a broader patent had held that the improvements shown would have suggested themselves to any intelligent mechanic; but on the reissue Judge Coxe takes a fitting opportunity to praise work which lies at the bottom of the real success of electric lighting, and which it seems to us differentiates the inventor very distinctly from the mechanic. There are broadly two classes of inventors, one of which grasps the underlying philosophical principles and gives the world a wealth of broad, new ideas. Electricity to-day is suffering from an embarrassment of riches in this respect, having all the ideas it can use for a century to come. The other class of inventors comprises men of a mechanical turn of mind who see how the new ideas can be adapted to old conditions, or can be carried out in novel but operative devices. Occasionally a great inventor comes along who has a place in each group, but as a general thing, the work of the first class depends greatly on the work of the second, and without it would often fail to materialize in public benefits. Mr. Stieringer and other men of insight like him have placed the arts under great obligations by the inventive mechanical faculty of high order brought to bear on the weighty problems of smelting true metal of practicable forms out of the crude ore of fundamental inventive conceptions; and we are only sorry there are not more like him. The electrical business to-day stands sorely in need of men who will improve, perfect, cheapen, and simplify hundreds of its existing devices and invent others without which many of the new arts limp along in immaturity.

THE SOUTH NORWALK MUNICIPAL LIGHTING PLANT.

A LITTLE over a year ago we published a description of the municipal electric lighting plant at South Norwalk, Conn. This plant has been pointed to as a model of its kind, and this year's report, by the commissioners having it in charge, shows a still further reduction, from 19 2-10 to 19 cents per lamp per night. Advocates of municipal plants are so prone to seize upon the figures of plant operating expenses without inquiring into the details by which given results are reached, that it may be well to remark here that the South Norwalk plant is operated on the moonlight schedule, and ran last year 317 nights, shutting down regularly, between 1:30 and 2 A. M. It will be noted, therefore, that the city is not lit all night. In calculating the cost per lamp the report very properly includes the interest on bonds, and all apparatus subject to wear and tear has been charged at 5 per cent. for depreciation. Accepting these figures as they stand they show excellent management, and just what one might expect from a private plant with an owner alive to his own best interests. But the conditions which so nearly approximate private ownership in South Norwalk are just those which cannot be counted on to exist in other cities, as a rule. To begin with, the Electric Light Commissioners at South Norwalk serve without salary, and one of them, an electrical engineer himself, has the plant constantly under his professional eye, and volunteers his professional services free. Adding as small a sum as $1,000 as salary of the Commissioners or for professional services to an outside consulting electrical engineer, would increase the total present yearly operating expenses ($5,902.25) close on to one-sixth, bringing the cost up to 22½ cents per lamp. Taking all the conditions into consideration, therefore, and not even including loss of city revenue from water and real estate tax which a private plant would have to pay, we do not see that the results reached at South Norwalk are remarkable. Indeed, they go to prove what we have all along contended, that the conditions for successful municipal plants are just those which, sad to say, are thus far wanting in American cities. It would, we believe, be a difficult matter to find another such patriotic commission as that having in charge the municipal electrical work at South Norwalk, and we extend to that commission our congratulations on their excellent work. But we would like to utter a friendly note of warning as to the contemplated extension of the city's plant for the purpose of furnishing light to private customers. The revenue obtained from private consumers, it is expected, will eventually pay the expenses of the public lighting, so that the city will be in the lighting business for actual profit. This is in direct opposition to the fundamental principles of the "municipalites," and we think the days of the commission's happiness would soon be over. If we are not greatly mistaken, electric light consumers would "kick" vigorously against being compelled to pay for street lighting which is intended for the benefit of all citizens and to which all should contribute alike. But aside from this consideration, the business of private electric lighting, as a business, is so entirely different from that of public lighting that to make it successful requires a combination of elements which cannot be reasonably hoped for under municipal management. For the sake of the commission's past good record and for their future peace of mind, we would urge them strongly to stick to their present restricted public lighting only.

WHAT WE ARE COMING TO IN TELEGRAPHY.

WITH a view to ascertaining the highest speed at which telegraphic characters can be legibly recorded, Mr. P. B. Delany, in some recent experiments, succeeded in transmitting by his machine system 8,000 words per minute, and obtained a plain reproduction of the signals by electrolysis on the chemically prepared receiving tape. The circuit was an artificial one of 650 ohms, 2.95 microfarads, and the electromotive force was 115 volts. This is about the equivalent of an ordinary telegraph line of 100 miles in length, or, say, New York to Philadelphia. At this speed the perforated tape upon which the messages were composed passed through the transmitting machine at the rate of 27½ feet per second, and the impulses comprising the letters traveled at the rate of 2,500 per second or 133 words, equal to six ordinary telegrams of 22 words each in a single second. At this rate the next few years must bring about great changes in methods of correspondence, and, inevitably, a large portion of the ninety millions now annually expended on wheel transportation of the mails will be diverted to the telegraph. Why not?

CAN THE ARC BE SUPPRESSED?

PROGRESS in the electrical arts has done much to lessen the danger and destructiveness of arcing at switches, but with the constantly increasing potentials employed and the heavy currents now called for in lighting and railway service, the arc still possesses sufficient obnoxious qualities to make its removal well worth study and experiment. Mr. A. J. Wurts, whose classical work in suppressing arcing in lightning arresters is well known to our readers, has recently turned his attention to the arcing at switch contacts and on another page gives the results of his experiments thus far conducted. One cannot read this record without recognizing that, though scarcely begun, Mr. Wurts' work will end in the development of a practical method of arc suppression at all station switches; and that the time is not far distant when that manifestation will be considered a relic of barbarism.

TELEPHONY AND TELEGRAPHY.

CHAROLLOIS MILITARY TELEPHONE SYSTEM WITH SINGLE UNINSULATED WIRE.[1]

AMONGST the resources that modern science places at the disposal of armies in campaign, certainly telegraphy and telephony, notwithstanding their modest position, constitute most important aids to victory in modern warfare. With their aid, commanders of armies can centralize almost instantly all the information required, and thus arrange their forces as advantageously as possible. By their means remarkable precision and rapidity are imparted to military operations. In

FIG. 1.—THE CHAROLLOIS ARMY TELEPHONE SYSTEM.

short, they enable orders to be transmitted in all directions with the precision and promptness of direct commands. It was by endeavoring to impart to the telephone, as used for campaigning, all the practical qualities that it lacked, viz., simplicity, lightness, solidity, facility and rapidity of installation, convenience in communication, and to render the very valuable auxiliary easy of manipulation that Captain Charollois, of the French Army, was at first led to use only a single wire for his telephonic transmissions, using the earth as a return.

This first point is of great importance in itself; but its value is enhanced by the proof of the uselessness of insulation in the wire. In fact, as the result of numerous experiments, Captain Charollois showed that a metallic wire, unwound along the ground, without any precaution as to insulation, had the property of conducting to comparatively great distances—20 kilometers at least—the induced currents circulating between two electric, or even simply magnetic, telephones, placed at the extremities of this single wire, considered as a line, the return being made through the earth. After many experiments and trials, Captain Charollois has been led at last to use a compound wire of pure copper, with a steel core. This wire possesses all the qualities for the purpose, conductivity, solidity, lightness, flexibility; it does not become oxidized, and is inexpensive.

Captain Charollois has also brought out a microphonic transmitter and receiver, so sensitive that conversations can be exchanged in the ordinary voice, at a distance, without having to lean over the apparatus, as we generally have to do with ordinary telephones. To obtain greater precision in communication, and, above all, to render the call bells more distinct, small dry batteries are used, attached to the transmitter, and enclosed with it in a sheet iron case for protection.

The telephonic post thus formed is carried on the back, and communication is obtained by uncoiling the wires by means of a special reel, the return being effected through the earth by the employment of rods, or even bayonets buried in the ground and connected with the post by earth terminals. Fig. 1 shows the soldier provided with an electrical telephonic apparatus fixed on his back by means of straps, like the ordinary knapsacks, and holding in his hand an unwinding spool. The engraving represents the traveling post at work, with the bayonet buried in the earth for the return circuit. Fig. 2 shows the transmitting apparatus.

Organization of the Regimental Telephone Service.—This organization comprises two distinct services: 1. The regimental services, entrusted to the sappers. 2. The company service, entrusted in each company to four soldiers and a corporal appointed by the captain.

The Regimental Service.—The object of the regimental service is to establish telephonic communication between the regiment and the brigade or division, and also for all operations requiring lines of great length. On fields for shooting practice, these movable telephone lines are also used, and they are of the greatest service in artillery practice and regulation shooting. These lines, which consist of wires 6-10 of a millimeter in diameter, may be 20 kilometers in length, and must often remain in position for several days without being taken up. They have, therefore, to be laid with a certain amount of care; the apparatus required is as follows:

Regimental Apparatus.—Six unwinding reels, 6 kilometers of wire; six magnetic telephones, three hooked bamboo rods, four earth terminals, four hooks for suspending the telephone. The weight of the reel, when wound with 1 kilometer of wire, is 3.5 kg.

The Company Service.—The object of this service is to enable the company to establish, under any circumstances of the campaign on the field of operations, one or more telephone lines capable of attaining a total length of 4 kilometers. The principal cases in which they are used are as follows: To connect the main body with the sentries and with the outpost reserves; to transmit to the main body the information gathered by the patrol; for use in the cantonments; the connection of detached services over irregular ground, mountainous or wooded districts, etc. The judging of distances in shooting practice.

As these company lines are always established on peaceful territory, there is no need to suspend the wire, and it is simply unwound along the ground. The company apparatus has, therefore, been reduced to the simplest possible form by using wire 4-10 of a millimeter in diameter wound on a spool of small dimensions, and suppressing the bamboo rods.

Company Apparatus.—Two unwinding reels, 4 kilometers of wire (2 kilometers per reel), four magnetic telephones, three earth terminals, three telephone suspension hooks. The weight of the complete reel wound with 2 kilometers of wire is 2.5 kg.

Establishment of a Regimental Line (Fig. 3).—Suppose that a line of 6 kilometers is to be established: the corporal, or a supplementary operator, takes up his position at the point, a, placing his telephone to his ear, connecting it by one of his conductors with the lines, and by the other with his bayonet

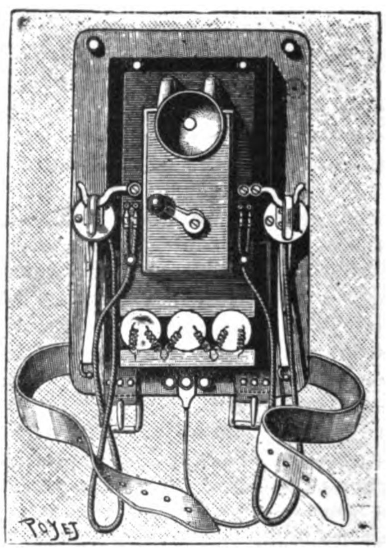

FIG. 2.—THE CHAROLLOIS ARMY TELEPHONE TRANSMITTER.

stuck in damp soil. The first set of men begin to unwind the wire. To do this, the bearer of the reel marches in the direction, b, at quick march, without troubling about the wire he leaves behind him. He takes care to march towards the supports to which the wire is to be hooked or suspended. His comrade, who is provided with the hooked rod, follows him, and hooks the wire to the natural supports that he finds on the way, trees, houses, hedges, etc. In default of natural supports, the wire is allowed to lie along the ground, preferably in furrows, trenches, etc.

[1] From "La Nature."

The line, whether suspended or lying on the ground, must be protected from any conditions likely to cause its breakage.

The first set of men having unwound their 2,000 metres, the

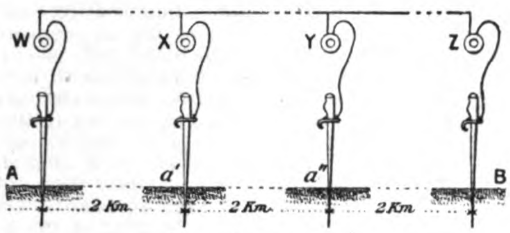

FIG. 3.

bearer of the telephone takes up his position at a', an intermediate post, as has already been done at point A, and at once enters into telephonic communication with his comrade at the head of the line. When the bearer of the rod for the first set has finished his work he holds himself in readiness to inspect the line, so as to find out and repair any accidental breakage that may have occurred, and that would be indicated by the cessation of communication. Thus these two men have the charge and superintendence of the portion of the line that they have laid down; they become, so to speak, the guards.

The second messenger, having attached his wire to the line, proceeds, as has already been explained, for the first. This operation is continued as far as B. The line of 6 kilometres will comprise four telephonic stations; two terminal ones at the ends of the line, A and B, and two intermediate, a' and a", for the inspection of the line. All these stations are in communication with one another.

This arrangement of the military line explains how unceasing surveillance can be exercised, how accidental breakages can be repaired, and, lastly, how it was that a line of 25 kilometres was able to be taken up in one hour during the Eastern maneuvers. The order having been given to all the stations at the same moment to take up the line, each set took up the line that they had laid down.

Communications with Operators on the March.—In this case the operator, with his left hand, keeps the sword bayonet connected with the telephone at his ear. The current is then permanently established, even during the march, through the body of the operator, and his feet which tread the soil. Every call from the main body is distinctly heard by the telephone operator or horse soldier, who stops and replies.

Employment by Cavalry.—This telephonic system can be of great service to cavalry regiments for the rapid conveyance of information gathered by reconnoitring parties and sentries.

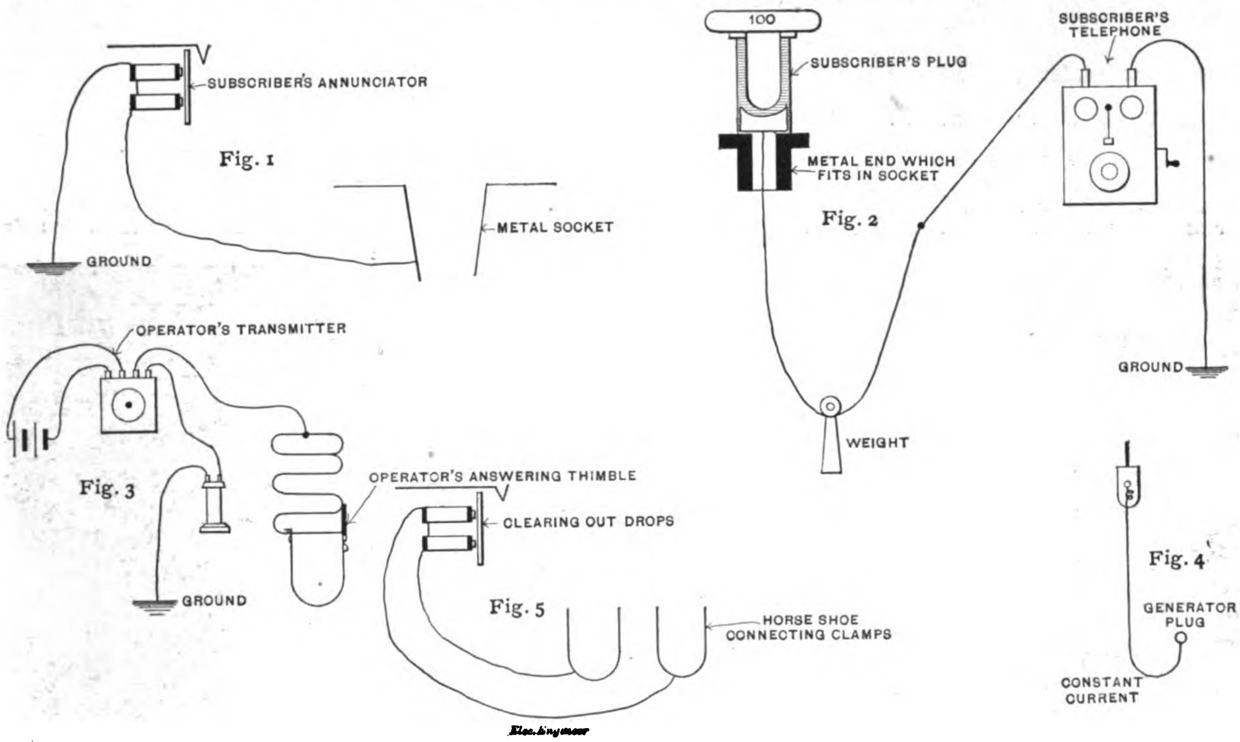
The modes of communication are the same as for the infantry. Nevertheless the horseman can, as described above for the foot soldier, be in constant communication, even when on the march, with headquarters. His telephone, which is at his ear, is in direct communication with the line by one of its conductors. The other conductor is connected with the bit, and consequently to earth through the body and shoes of the horse. If it should be necessary to establish a telephone line very quickly, the wire might be unwound by a cyclist. Extending the application of his naked wire system of telephony to everyday uses, Captain Charonnis has also constructed a series of instruments meeting ordinary requirements, and forming altogether a system of civil telephony that can be utilized in various ways.

THE SWARTS "MULTIPLE RIVAL" TELEPHONE SWITCHBOARD.

THE new telephone exchange recently put in operation at Knoxville, Tenn., is equipped with a type of multiple switchboard possessing a number of interesting features which conduce to rapidity of manipulation and in the arrangement of which special provision has been made for convenient handling by a smaller number of operators during the hours of few calls. This board, which is the invention of Mr. H. J. Swarts, manager of the People's Telephone and Telegraph Company, of Knoxville, Tenn., is a multiple board, and in its horizontal features recalls somewhat the old "Law" switchboard. In its details, however, it differs essentially from that type of construction. The engraving Fig. 6 shows the board in its normal position for the full force of day operators on duty in their respective positions. Fig. 7 shows the annunciator boards, which are adjustable, faced toward the table, carrying the subscriber's lines, this being their position for night and Sunday work when only a small force of operators is required.

As will be seen, the pegging table around which the annunciator boards are placed, is spaced into sections of 100 wires each, the arrangement being such that an operator at any section can reach to any subscriber wanted on any of the other sections, and make the connection for any of her subscribers without the assistance of any of the other operators and without moving from her seat. The engraving shows only six sections connected, each section being for one hundred lines; space is left to connect 400 more lines, which can be added as desired. When these are added the board will form a complete circle.

The diagrams, Figs. 1 to 5, show the circuit connections with



FIGS. 1 TO 5.—SWARTS TELEPHONE SWITCHBOARD.

the subscribers' line ending in a flexible cord, through metal socket to annunciator, and ground. It is obvious that in place of the plug, cord and socket there could be substituted a spring jack, using connecting cords and plugs in connection with the

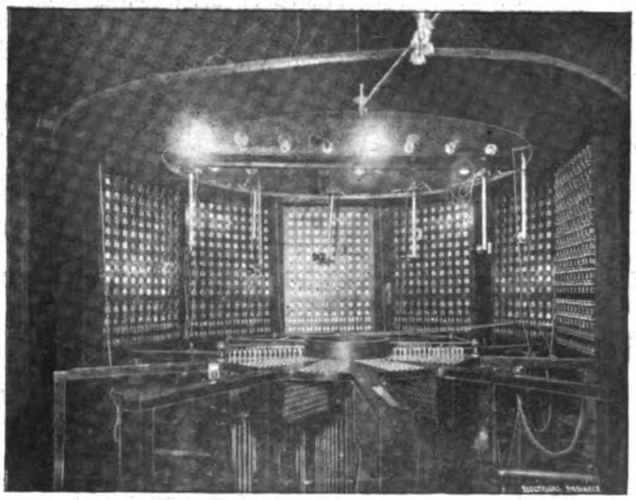


FIG. 7. THE SWARTS "MULTIPLE RIVAL" SWITCHBOARD.

spring jacks. In Fig. 1 is shown a line from socket to annunciator, thence to ground. Fig. 2 shows the subscriber's plug to subscriber's telephone. Fig. 3, the operator's transmitter, receiver and answering and listening thimble. Fig. 4, the generator plug. Fig. 5, the clearing out annunciators and connecting clamps.

The subscribers' plugs are numbered on top. With the line not in use, tne subscriber's plug rests with its metal in the socket, completing the circuit from telephone to ground through the annunciator. When the subscriber rings the operator lifts his plug from the socket, thus throwing out his annunciator, and presses the plug firmly between her thumb and finger, on which she wears the metal thimble that connects to the line post of her transmitter. This places her in connection with the calling subscriber, and, it wil. be noted, only one movement has been necessary to establish communication. As soon as the operator is told the number of the subscriber wanted she places the calling subscriber's plug into the connecting clamp, reaches and gets the cord or plug of the subscriber wanted and touches his plug against the generator plug and then places it into the connecting clamp that is a mate to the one where the calling subscriber has been placed. If any line is busy the fact is at once apparent; the plug of the busy subscriber being out of place and the cord drawn up through the socket, or, where spring jacks are used, a plug would be inserted. Mr. Swarts, the inventor of the board, makes the claim of being able to give a quicker service to an exchange up to 1,500 subscribers than can be given with any other switchboard, as there is no testing apparatus necessary to know if a line is busy, and only one-third of the amount of wire is necessary to wire up as required for the multiple board.

The board illustrated is designed for 1,000 subscribers, but can be made to accommodate 1,500 if necessary. It has been in operation for two months past in the new exchange of the People's Telephone and Telegraph Company, of Knoxville, with excellent results.

PACIFIC CABLE PLANS.

The United States Senate Committee on Foreign Relations on March 11 considered the two propositions before it provid'ng for the construction of a telegraphic cable from San Francisco to Japan, via the Island of Hawaii. No conclusion was reached by the committee, but it is believed that one of the two companies will be granted the right to construct the cable and be given a bonus by the government.

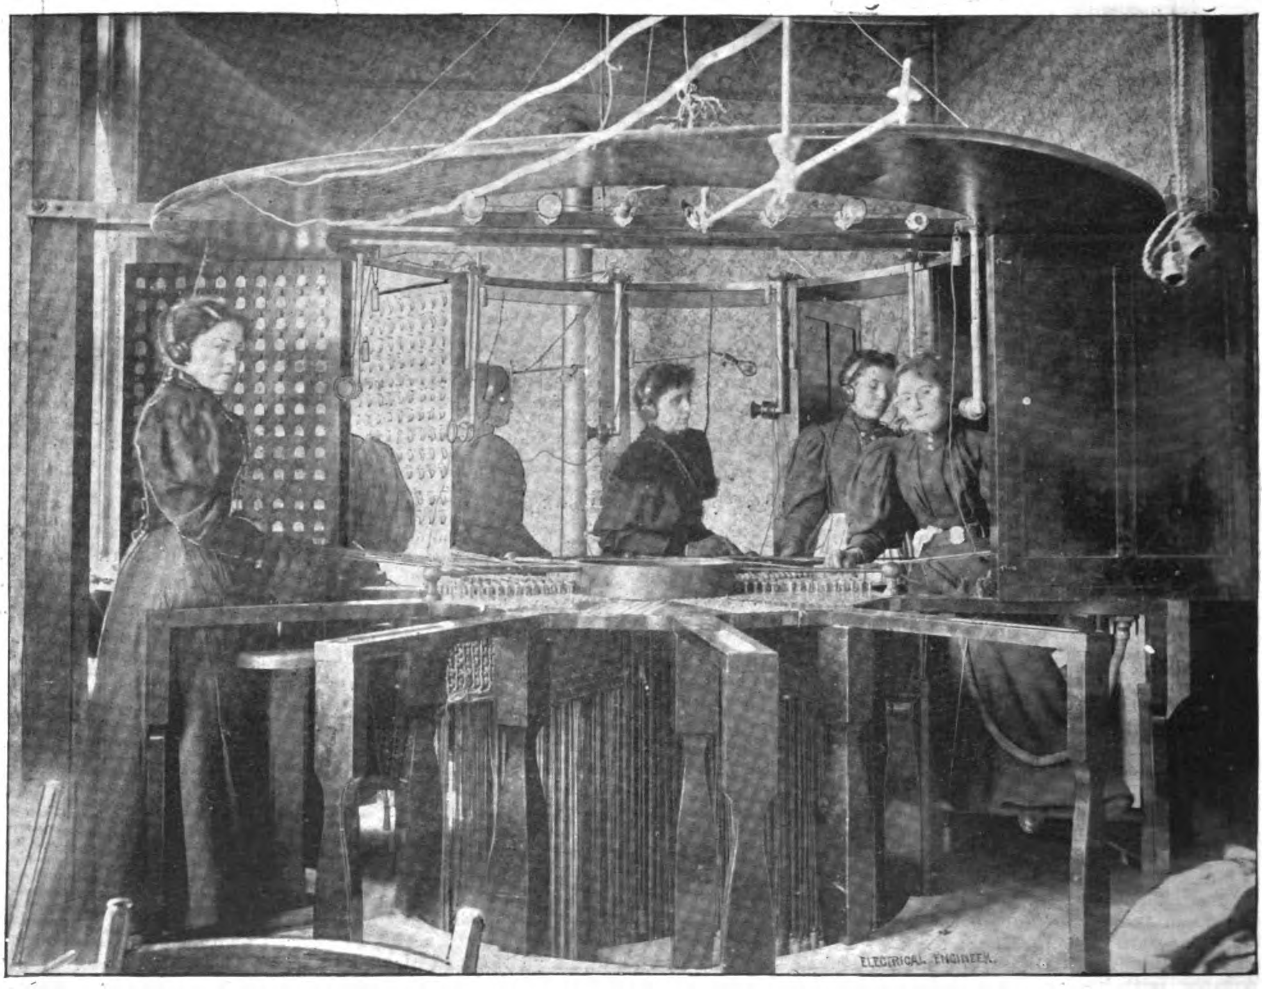

FIG. 6. THE SWARTS "MULTIPLE RIVAL" TELEPHONE SWITCHBOARD.

Power Transmission.

DISTRIBUTING POWER AND LIGHT FROM SINGLE PHASE ALTERNATORS.

BY JOSEPH N. MAHONEY.

It is the object of this paper to show a method of utilizing the present simple alternating apparatus for the generation and distribution of power and light by polyphase currents with no more complication than that met with in a three-wire direct current system.

It is a well-known fact that in this country outside of the large cities the large majority of the stations are operated with apparatus of the simple alternating, single-phase type, as is also the case on the other side.

The periodicity used in this country is from 125 to 150 cycles per second generally, but in the newer installations it ranges from 50 to 60, in England from 80 to 100, and on the continent from 40 to 60 cycles.

Up to the present time the art of building self-starting, single-phase induction or synchronous motors for commercial purposes has not progressed very far, and in consequence the usefulness of the plant has been limited to lighting work for a few hours each day.

In some cases direct continuous current power generators and circuits have been installed to distribute power at 500 volts during the day while the alternating machines and circuits are lying idle. For stations operating under the above conditions the writer would propose the following: First, let us consider the changes necessary in the station. It would be desirable in some cases to lower the periodicity of the generators to 50 or 75 cycles per second. This is done without impairing the efficiency or output by changing the polarity of part of the field coils and armature coils, thereby changing the number of active poles and also the periodicity. Any generator having a multiple of three or four poles can have the periodicity lowered to one-half or one-third of the present rate by this method.

It will not be necessary, in most cases, to lower the periodicity, and, in fact, it would not be desirable, as it would necessitate a change in transformers, as multiphase motors are being built that will work perfectly on circuits of 125 to 150 cycles per second.

The simplest and most flexible method of operating the generators will be found in the diagram at G, where two simple alternators are shown rigidly coupled mechanically to give two e. m. f.'s with a phase difference of 60 degrees, equal in effect to the e. m. f.'s of the generator of the so-called monocyclic system.

The generators need not necessarily be of the same size, the load being so distributed with regard to the two generators as to load them proportionately according to size, nor of the same make; but they must have the same periodicity and also the same speed, otherwise they would have to be geared to couple them rigidly, a belt connection allowing of a slip which probably would change the phase relation of the two machines.

Out of this connection can be had single phase monocyclic, diphase and triphase currents for operating motors and other translating devices requiring them. This is done with the aid of two suitably proportioned transformers, as shown in the diagram.

The handling of the generators will be practically the same as in the three-wire, direct current system with compound wound generators, the alternators being ordinarilly compounded and compensating automatically for the drop in potential occasioned by the resistance and reaction of the armature and line as the load varies on its side of the circuit.

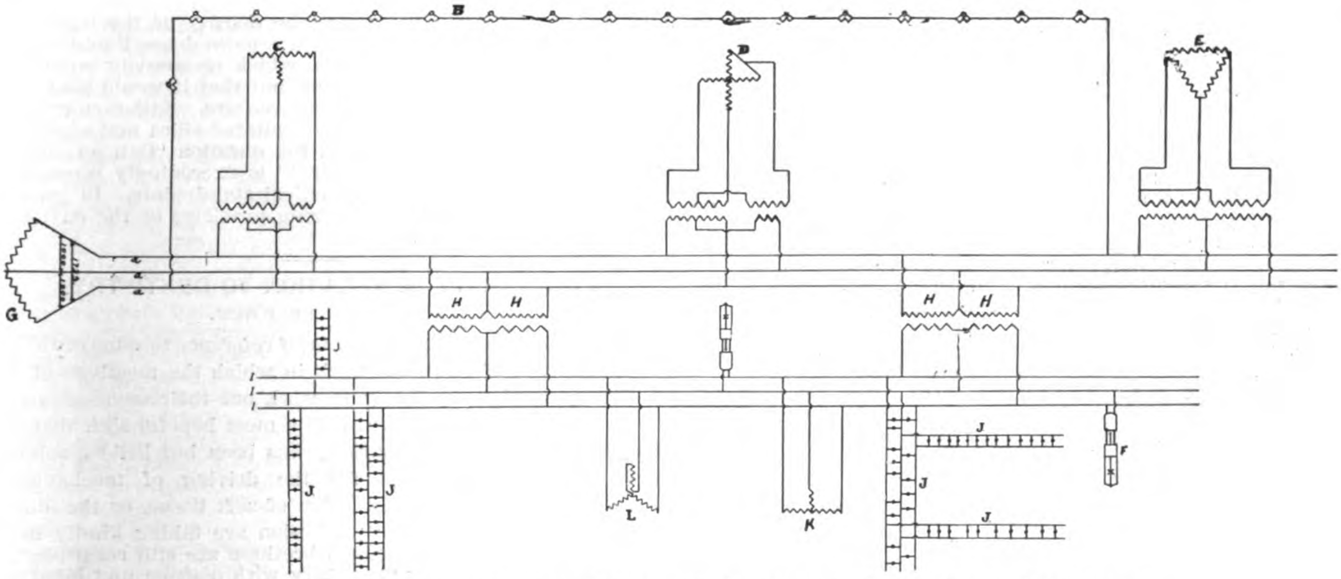
The line, and, in fact, the whole installation, would be relaid out as if it were to be a three-wire alternating current system, the only difference being that the generators, instead of being connected in straight series, would be connected in series with the slight phase difference of 60 degrees between the maxima of their e. m. f.'s. The e. m. f.'s impressed on the line would be, in the case of 1,000-volt generators, a mean difference in potential of a 1,000 volts between the neutral and either outer conductor and 1,733 volts between the outer conductors; and 3,466 instead of 4,000 volts in the case of 2,000-volt generators.

The secondary mains either overhead or underground would be operated from two transformers off the primary mains, the same as ordinary Edison three-wire mains, with the lamps connected between the outers and the neutral, and would have the advantage over ordinary three-wire alternating mains in that self-starting induction or synchronous motors could be operated therefrom without the intervention of any extra transformers, power wires, or apparatus other than that already contained in or on the motor.

These arrangements are shown in the diagram presented herewith. Here a, a, a are the mains or feeders leading from the station, to which are connected the circuit B, of either series incandescent or arc lights in parallel with reactive coils; C, a monocyclic motor in circuit with transformers; D, a diphase motor and phasing transformers; E, a triphase motor and phasing transformer. H, H, H, H, are large transformers feeding the secondary mains I I I, from which are operated the two and three-wire lamp circuits J J; the arc lamps F F with economy coils; tne monocyclic motor K, and the triphase motor L.

It will be seen that it makes a really flexible system of distribution with very little complications. The cost and bother of changing over would be nominal in most cases, as the only change necessary in the station is to shift the alternators so that they can be connected mechanically in pairs and driven from the engines or countershaft, as before.

The apparatus on the dynamo switchboard will be the same as if no change were made, each generator being regulated separately, the generator cables or bus' being connected electrically together after leaving the dynamo switchboard. The panels of the feeder board, if there be any, will be coupled up in pairs, each one of a pair controlling one side of a three-wire feeder. The present feeders and mains, consisting of two conductors, will be supplemented by third conductors of one-half the cross-section of either of the other conductors and we



Mahoney System of Distribution of Power and Light from Single Phase Alternators.

are at once able to transmit twice the power that we were before with only a 25 per cent. increase in copper. The transformers already installed will be connected between the small wire and either of the two larger wires instead of between the two large wires, as heretofore. Branches to transformers where only light is needed will consist of two wires only.

MISCELLANEOUS.

CAN AN ELECTRIC CIRCUIT BE OPENED WITHOUT AN ARC?

BY A. J. WURTS.

THE opening of an electric circuit is ordinarily accompanied by an arc which causes more or less damage to the switch terminals. The extent of this damage is in general dependent on the amount of current flowing and on certain characteristics of the circuit and generating apparatus.

Up to very recent times electric circuits have been handled with switches constructed without special reference to arcing, the deteriorating action of the arc not being sufficient to warrant special constructions. With modern lighting and power transmission circuits, however, the problem has assumed quite different proportions, so that, not only are ordinary switches rapidly destroyed in the handling of these circuits, but an element of danger is also introduced. To-day electric arcs six feet long are not uncommon.

While experimenting some time ago with static discharges I had occasion to pass a small discharge across a 1-32-inch gap, between electrodes which were placed in a heavy glass tube filled with oil and securely corked at either end. Much to my surprise, at the time, when the discharge occurred the glass tube was broken into small fragments; it did not burst as by an explosion; the tube simply fell to pieces. The experiment was repeated a number of times with the same result. I subsequently analyzed the experiment as follows:

An electric arc requires space. The glass tube was filled with an incompressible fluid possessing considerable inertia. An arc which might form within this fluid would be obliged to displace the fluid, which, in turn, being incompressible, would force out the walls of the containing vessel; the latter being brittle, were broken into fragments. The force which broke the vessel was the electromotive force which forced the arc across the spark gap. The elastic corks could not play the part of cushions and thereby save the tube, because the displacement of the oil was sudden—the oil was not pushed away by the arc, but knocked away, as with a hammer—and because the inertia of the oil between the arc and the corks was greater than that between the arc and the walls of the tube; in other words, the force became active in the direction of least inertia. Reasoning further, it seemed that if the vessel had been relatively stronger than the electromotive force, the arc could not have formed; in other words, it seemed as though the elements were at hand for the construction of a switch capable of opening an electric circuit without an arc.

Following out these ideas, I constructed an ordinary electric switch of about 100-amperes capacity, which was suitably located in a sealed cast iron vessel filled with oil. On placing this switch in a 500-volt direct current circuit, I opened and closed the switch some eight or ten times on 30 amperes and upon removing the stopper from the cast iron vessel was surprised to see the oil spurt. On examining the oil, I found it had been considerably carbonized. The accumulation of pressure and the carbonization of the oil indicated the formation of an arc at the switch terminals, which for a time puzzled me considerably, as the formation of an arc had not entered into my calculations. On repeating the experiment I neglected to replace the stopper, with the result that when the switch was opened a column of oil was forced into the air about six feet high. Testing again with the vessel closed I detected a slight gurgling sound when the switch was opened.

Being still puzzled, I determined to see what was going on within the vessel and had a heavy glass front constructed. Repeating the experiments, I noticed that on opening the circuit an arc was formed about the size of a pea. The same arc in air would have been about three inches long. After about a dozen breaks, however, the glass front was shattered, as though struck by a hammer. On further considering these results, it seemed to me that either the vessel had not been entirely filled with the oil or that the vessel was sufficiently elastic to allow the formation of the small arc noticed. It is not unlikely that both of these conjectures were true. However, the arc which actually formed was so insignificant that I felt encouraged and proceeded with my experiments, hoping to eventually produce results of practical value.

My first step was to overcome the pressure which accumulated, due to the formation of gases by the arc in the oil. I placed in connection with the containing vessel a small reservoir, having a direct pinhole communiction with the main vessel, also a valve connection allowing oil to pass from the reservoir into the main vessel by gravity. The pinhole communication was placed in a dome directly over the switch terminals, so that the gases which formed would rise to the top of the dome and pass out into the reservoir, which latter was only partially filled with oil. The pressure being thereby released in the switch chamber, sufficient oil would flow through the valve communication from the reservoir to occupy the space which had been previously occupied by the gas. This plan proving satisfactory, I proceeded to determine the life of the switch as compared with a similar switch used for the same purpose in the open air. After making about 3,000 breaks I found that the oil had carbonized to such an extent that with the switch open there was a current leakage of several amperes. Various oils were subsequently tried, some of which proved better than others. Of these paraffine oil gave the best results.

I next tried glycerine and with it made 40,000 breaks. At the end of this test the switch terminals were found to be slightly scarred, the glycerine was black from carbonization, but the current leakage was only a small fraction of an ampere on open circuit.

Having arrived at this point, I began to experience difficulty with the containing vessel, which now leaked badly in spite of the best fittings I could procure. To overcome this difficulty, I determined to increase the density of the liquid. It seemed to me that not only would a more dense liquid be less easily forced through the joints, which necessarily enter into the construction of the apparatus, but that it would also more effectually resist the formation of the arc. Satisfactory tests were made with a mixture of precipitated silica and glycerine.

Aside from the above results, the question "Can an electric circuit be opened without an arc?" is exceedingly interesting from theoretical as well as practical standpoints. In connection with the electrical engineering problems of the day, it is one of no small importance.

ELECTRICITY IN RELATION TO DENTISTRY.[1]

BY GEORGE HELI GUY.

I SHALL confine myself to a brief reference to some of the departments of electrical work in which the members of the dental profession are likely to work out their own salvation. In considering this question, it is a most hopeful sign that, although until recently, electricity has been but little employed in dental surgery, except for the driving of mechanisms, cauterization, the translumination of soft tissue, or the illumination of cavities, yet the profession are taking kindly to it. A large section of your medical brethren are still regarding its progress and increasing popularity with distrust and blind unbelief. Not long since, I asked a leading fashionable physician in New York his opinion as to the likelihood of electricity being eventually taken up in earnest by the profession. He replied: "It never will be. I have tried it myself, and have come to the conclusion that there is nothing in it." The whole electrical apparatus of this physician turned out to be a small faradic battery, and he had been treating all ailments with the same kind of current. There are thousands of practitioners who still think as he did. But there are many signs which go to show that the progressive and intelligent section of the dental profession are going with the times, and I was struck, and very much gratified, when attending the Dental Convention last year, at Asbury Park, to see the intense interest and appreciation with which the papers discussing electrical problems were received. I read not long ago of some electrical experiments upon floating organisms. If a galvanic current be passed through a bath containing paramecia in sufficient abundance, a curious sight is observed. When contact is made, the whole crowd of paramecia fall into order with their noses toward the cathode, and begin to swim toward it in converging curves; while, if the current be reversed, the crowd breaks up, all its units turn around and begin to swim away, as if of one mind, from the new anode to the new cathode. The creatures are evidently more "comfortable" when swimming with the electric current than the reverse way. In another experiment, a number of tadpoles were put into a lantern bath. They began to move about very leisurely, and to jostle

1. Abstract of response to toast of "The Coming Dentist Electrically Considered," at the annual dinner of the Central Dental Association, of Northern New Jersey, at Newark, N. J., Feb. 17, 1896.

each other in all directions. On sending a current of electricity through the bath there was prodigious excitement. As Dr. Waller, who conducted the experiment, described it, "The tadpole community seems to have gone mad; a writhing mass is all that can be distinguished; but the disturbance does not take long to subside, and now all the tadpoles are fixed as if at attention, heads to anode, viz., traversed by a current from head to tail, stroked down the right way." It appears to me that the dentists, like the tadpoles, have begun to find that it is wise to yield themseves to the current of electrical progress that has set in; it points their heads the right way, and means, in the long run, less trouble, better work, and last, but not least, relatively better pay.

One of the great drawbacks to the adoption of electricity in general dental practice is the cheap outfit and the poor installation work. Any man who can put up an electric bell now calls himself an electrician. If it were not for the inspection department of the Board of Underwriters, there would be, from bad wiring, such a crop of fires in large cities as would render the lighting of the streets entirely unnecessary. But there are no such adequate official restrictions and precautionary measures for the protection of the dentist. Beware of cheap outfits. Don't try to save a dollar or two in your battery plant; get the best that is in the market. Go, for your motors, and your dental equipment, to the best houses, that spend money on experimentation instead of letting you pay for it directly, and that insure careful inspection, and sound installation, and don't subject you to the curses of defective wires, poor plugs, and inferior tackle of every description. I know of an instance in New York, where the dentist had the hard luck to be taken in hand by a cheap, so-called electrician. Before he got through, he spent $500 in his electrical outfit, and then he threw it out and vowed he wouldn't have anything more to do with electricity, as it was a rank fraud. Therefore, I say dental electric outfits are like bicycles; if you want one to wear well, run smoothly, and save lurid language, get the best you can lay your hands on; you will get gratifying results, and you won't have any hard things to say about electricity.

Now, as to the electrical possibilities of the future in dentistry. Although we can't gauge them, we have been lately getting some glimmering as to the trend they are likely to take. I wish I could help saying something about cataphoresis; but I can't. The coming work in cataphoresis will not only be vast in extent, but marvelous in its general bearing on dental practice. Many occasions constantly arise where anaesthetic drugs may be introduced into tissue and into dentine, and also other drugs, such as iodine, etc., may be used in the same way, and their familiar topical effects be vastly enhanced by the aid of electricity. Few can comprehend the limitations of this great aid to the local application of drugs within the cavity of the mouth. Broadly, it may be said that any drug that has been previously used without electricity within the mouth to produce specific effect, may now be electrically used with tenfold its former power for good. The subject of cataphoresis is already very wide, and I am not going to enter further upon it. I would, however, say, as it leads up to another point, that the question of the resistance of the liquid used has a most important bearing in the therapeutical applications of cataphoresis. If the resistance is too high, as with chloroform, sulphuric ether, alcohol, glycerine, etc., little or no current is conveyed, and no cataphoresis takes place, while on the other hand, if the electric resistance is too low, as with strong saline and acid solutions, much current passes, but little or no cataphoric action takes place. Now, you are all familiar with the points of the late discussion on guaia-cocaine. It may be, and undoubtedly is, an excellent anaesthetic, but it is ill-smelling and escharotic, and none of you like it. It has been proposed to add almond oil to it, but if the resistance is thus increased, more current will have to be used. Dr. Morton, however, has found a way out of the difficulty. He says that guaiacol alone, and other similar substances and derivatives, in themselves non-conductors of electricity, by the addition of a very minute quantity of some innocent substance of an electrolytic nature, like; say, salts of caffeine or quinine, or any salts of the alkaloids, may be caused to penetrate tissue by the aid of electricity, and thus exhibit anaesthetic effects unobtainable without the aid of the added electrolyte. But this is one of the points that you gentlemen will have to straighten out before the best results from cataphoresis can be reached.

Further developments in the uses of the different kinds of currents is another subject which is too comprehensive to be discussed here. I may, however, promise that the sinusoidal current will sooner or later find its way into dental laboratories. As you know, a dynamo current is uneven, but the sinusoidal, with its very high vibrations, has soft, wave-like impulses; the current is agreeable and soothing to the patient, and more horse-power of electricity can be administered than if the frequency were lower and the wave less symmetrical. For example, the present sinusoidal machines run up to 2,000 alternations per second, whereas the alternations per second of an induction coil would be, probably, at their highest limit, 500 per second. Added to that, the graphic curve from the induction coil would be comparatively unsymmetrical, i. e., irregular. It is these two elements, the frequency and the graphic curve, or, as D'Arsonval calls it, "the characteristic of excitation," which determines whether the current is painful or not, and it is pain only, which limits the extent to which the induced currents from ordinary medical apparatus may be administered. On this head, I may mention, that guesswork in electrical dosage will soon be a thing of the past. The time is approaching when electricity will be prescribed and administered not only in measured units of intensity, density, and time, but with definite ideas of the electromotive force curve, and of the therapeutic indications that a given curve may be expected to fulfill.

There are many other branches of electrodental work in which we are on the verge of epoch-making improvements, and among them are the important ones of transiumination, implantation, and sterilization. For the purpose of transilumination, it is probable that more attention will be paid to the intensifying of the light. For instance, instead of confining the lamps for that purpose to small candle-powers, they might be run up to, say, 20-candle-power. Until lately, the difficulty has been that candle-power produced heat. This has been practically overcome by enclosing the first bulb in a second bulb through which water is made to flow. But here comes the fascinating question of the part which the phosphorescent, or "etheric" light, the "Tesla glow," or, as it is also called, "the light of the future," will play in transiumination. I had the pleasure about two years ago, of seeing, in Mr. Tesla's laboratory, a demonstration of the then newly developed phosphorescent light. The room was darkened, and electrostatic currents played into it at the rate of possibly a million vibrations a second. Vacuum tubes, in fancy shapes, lay all around, and as these were taken up and lifted into the "field" they burst forth into beautiful luminescence, and the room was illuminated. Tesla then prophesied that it would not be long before our houses were lighted without wires, and even without lamps, and that the night would be made as day by means of phosphorescent light caused by the play of current through air-exhausted tubes. Last year a photograph of Mr. Tesla was taken by this light. As a photograph it was not much to boast of, but as a piece of history, it was most interesting. It was the first time that a photograph had been taken by that light. That line of work was taken up by a man in your own city, Mr. D. McFarlan Moore, who in the short time that has since elapsed, has so developed it that he published a week or two ago, a bold and striking picture, possessing the clearness and strength of a daylight photograph, which was secured by a three-minute exposure under the new light in his laboratory. If such strides can be made in twelve months, and we are coming at such a rapid rate nearer to the electrican's—and, for the matter of that, the dentist's—ideal, of light without heat, I think it may pay the dentists to let their spirit of investigation drift in the direction of transiumination by phosphorescent light.

Electricity as an agent in implantation, etc., of teeth is a very attractive subject, and we are on the eve of great developments in this field, but I must not detain you longer.

There is, however, an incident which I should like to tell you of, which bears on another important branch of work, sterilization. Some time ago, a German physician wrote to Mr. Tesla and said that he had been experimenting with the play of etheric light on the bacilli of tuberculosis, and not only had he killed the microbes while experimenting, but he had by the same means cured tubercular developments in the human subject. This letter, sad to say, was burnt up in the fire at the laboratory, and Mr. Tesla has never been able to find where it came from. Now, gentlemen, you will see how beautifully this bears on the question of sterilization: pyorrhoea alveolaris should have no further terrors when it can be swept out of the human jaw with a brush of glowing phosphorescence, and a new charm will be given to dental work when light will not only illume, but purify and sterilize, and even kill the deadliest germs that work havoc within the soft tissue of the mouth.

And now, gentlemen, the Röntgen rays—no speech to-day is complete without something about them. I don't think any of us yet realize what they may mean to dentistry. If it can be established that the cathodic rays will, like light, kill microbes, you see at once where it carries you. There is one thing, however, that cathodic rays have done, that you gentlemen, I am sure, will take careful note of. They have passed through ivory, and photographed pieces of metal on the other side. Where fangs and other parts of the teeth are being treated, it is often necessary to know which teeth already con-

tain filling. There is now no further difficulty about this. As metallic substances intercept light to a greater degree than bone does, a cathodograph will show the location of all the filling in the teeth which have already been operated upon. Dr. W. J. Morton has proposed to put the Röntgen rays within the cavity of the mouth, and a sensitive plate within the plate holder outside on the cheek, and thus reproduce the teeth, in situ, fangs, filling, etc. In this connection, it would also be possible to determine the existence of ostitis, deformations, diseases of the bone, pus deposits, etc., in fact, the whole concealed pathology of the teeth in their relation to the jaw and gums would be thus revealed.

COPPER PRECIPITATION PLANT, AT BUTTE, MONTANA.

THE accompanying illustration gives a fair idea of the largest copper precipitating plant in America. It is located on the side hill just below the Anaconda mine and the water as it is pumped from the Anaconda and St. Lawrence mines is carried in a flume several hundred yards to a large number of vats into which all sorts of scrap iron and tin cans are placed. The average time required to precipitate the copper is about one month, and the output averages nearly 100 tons per month of copper.

COPPER PRECIPITATING PLANT AT BUTTE, MONT.

Copper in its pure state is very sparingly soluble in water, and in the chemical form in which it exists in the Butte ores (chiefly as copper pyrites and copper glance Cu_2S) not at all, and it is necessary that it should become a copper sulphate. In this condition it is readily soluble and can be leached out of the matrix and carried up out of the mine in the water. It is not definitely known how this change is brought about in the veins of ore, but it is no doubt due in a great measure to the the inflowing water, carrying more or less oxygen in suspension with carbonic acid gas. All chemical changes and combinations produce more or less heat, and this would tend to accelerate the change in the conditions of the ore, the carbonic acid gas also playing its part by reaction on both the ore and matrix.

The great fire in the St. Lawrence mine in 1889 has, and is now, producing the same chemical change in the ore body, and in the same way that we find taking place in the heaps of burning ore at the Rio Tinto mines, the heat aiding the chemical alteration in the ore mass, and hence its waters are very rich in the copper salt, the assay value of which will probably average one-half of one per cent. of the body of water coming out.

We have in this mine water, in solution, the copper salt of sulphate, i. e., sulphuric acid in combination with the metal, and since this acid has a much greater affinity for the metal iron than the first named, immediately the solution is brought into contact with it, the acid at once leaves the copper and combines with the iron, forming an iron salt or sulphate, which is very soluble in water and the copper is precipitated as the pure metal, mixed with some impurities only; the iron salt passing off with the water. The precipitation of the copper held in solution as a salt from the water pumped from the mines and otherwise, is not a new thing. It has been in operation for many centuries, notably at the great Rio Tinto copper mines in South Spain, and at the long worked mines on the Island of Anglesea, Wales, where immense quantities of old scrap iron are annually consumed.—"Western Mining World."

THEORIES OF ELECTROLYSIS.

In the current number of "Science Progress" Mr. C. Dampier Whetham summarizes existing theories of electrolysis. Starting with the application of Ohm's law to electrolytes, he discusses the evidence which Kohlrausch educed in regard to the specific character of ionic velocities. The hypotheses of Arrhenius, Ostwald and others concerning dissociated ions are next considered, and a number of interesting tables have been compiled by the author bearing upon the coefficient of ionization and constants of affinity of a number of electrolytes. The dependence of general physical properties, such as the osmotic pressure, freezing point, etc., upon the electrolytic characteristics of the liquid are discussed in relation to the researches of Mr. H. C. Jones on this subject. From established data, the author proceeds to summarize the hypothesis in regard to the dissociation accompanying the solution of highly stable solids. In regard to this branch of the subject he arrives by independent reasoning at the conclusions: "That pairs of opposite ions must be separated, and the ions exist free from each other's influence, and, secondly, that there must be a tendency towards the formation of more or less stable molecular aggregates between salt and solvent." The apparent contradiction involved in these two conclusions is got rid of by the fact that "since it is evident that one salt molecule can influence a large number of water molecules, it follows that the chemical forces are very far-reaching."

MR. G. N. SPENCER and others are interested in a plan for delivering power electrically in Los Angeles, over a distance of 108 miles.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED MARCH 10, 1896.

Accumulators:—

SECONDARY BATTERY PLATE. I. Samuels, New York, 556,027. Filed Sept. 10, 1894.

The negative element is in two equal portions and arranged on opposite sides of the positive element.

Alarms and Signals:—

BURGLAR ALARM. T. J. Sutton, New York, 555,982. Filed April 9, 1895.

A sliding rod between two arms, one end of which is adapted to operate a push pin and the other end to enter the keyhole of the door.

ELECTRIC SIGNALING SYSTEM FOR RAILWAYS. G. L. Thomas, Brooklyn, N. Y., 556,072. Filed June 11, 1895.

ELECTRIC BLOCK SYSTEM FOR RAILWAY CROSSINGS. A. E. Ellis, Boston, Mass., 556,139. Filed Nov. 8, 1895.

Automatically switches off the power current from certain sections of the electrical conductor running parallel with the tracks if the crossing ahead is not clear or safe.

ELECTRICALLY OPERATED RAILWAY GATE. B. Haberthue, Logansport, Ind., 556,183. Filed Oct. 15, 1894.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE. W. M. Mordey, London, England, 555,963. Filed April 21, 1891.

A stationary non-magnetic armature having an annular series of coils and two series of rotating magnetic poles at opposite sides of said armature coils.

BRUSH FOR DYNAMO ELECTRIC MACHINES. F. J. & R. Chaplin, Birmingham, England, 556,176. Filed Dec. 10, 1895.

Consists of longitudinal wires crimped and grouped together into the required section.

Lighting:—

ELECTRIC CAR LIGHTING SYSTEM. A. H. Armstrong, Schenectady, N. Y., 556,079. Filed May 31, 1895.

A three-phase railway supply line, with motor-generator on the car for converting to continuous current, in connection with storage batteries.

Measurement:—

ELECTRIC METER. C. Wirt, Philadelphia, Pa., 555,992. Filed Nov. 30, 1894.

An electric oscillating motor for driving a register, and a cut-off controlled by a current indicator for cutting off the current to said motor at each oscillation, whereby the arc of vibration is made proportional to the current to be measured.

Miscellaneous:—

ELECTRIC GAS LIGHTING BURNER. J. A. & G. A. O'Neill, Boston, Mass., 555,968. Filed Nov. 16, 1895.

ELECTRIC ELEVATOR. H. R. Smith, Chicago, Ill., 555,979. Filed March 23, 1895.

A car, a hoisting cable therefor, a magnetic piece carried by said cable, a motor, comprising a solenoid, said magnetic piece forming the core of said solenoid, means for energizing various portions of said solenoid, whereby said core is moved and said car operated.

CAR COUPLING. C. Moradelli, Munich, Germany, 556,018. Filed June 16, 1895.

The car hoops are operated by magnets controlled from the locomotive.

ELECTROLYTIC APPARATUS. M. H. Wilson, Brooklyn, N. Y., 556,038. Filed May 8, 1895.

Employs a liquid electrode to prevent the disintegration of the anode.

PRESSURE RECORDING DEVICE. J. F. Batchelor, Brooklyn, N. Y., 556,081. Filed May 2, 1894.

A diaphragm operated by pressure, in combination with an electric time stamp.

PROCESS OF EXTRACTING NOBLE METALS FROM ORES. O. Frölich, Berlin, Germany, 556,092. Filed Aug. 3, 1895.

The metals are extracted from a lye containing 5 grains of each metal to the pint, using 12 amperes for each 2 square yards of cathode surface. This separates the gold.

ELECTRIC GAS IGNITER. J. P. Doyle, Buffalo, N. Y., 556,138. Filed Oct. 29, 1895.

A slotted gravity-cam hinged to the upper side of the bracket for vertically actuating the swinging electrode.

ELECTROTHERAPEUTIC BODY WEAR. G. Quarrie, Brooklyn., Mass., 556,161. Filed May 3, 1894.

A boot or shoe provided with a metallic insole having electrical connections through the sole of the shoe with the ground.

ELECTRIC GAS LIGHTING DEVICE. J. B. Jackson, Philadelphia, Pa., 556,189. Filed Aug. 15, 1895.

ELECTRIC CLOTH-CUTTING MACHINE. A. K. Thyll, New York, 556,224. Filed May 31, 1893.

Embodies an electric motor having two armatures, the field magnets of which extend in opposite directions and have three poles, one of which serves for both armatures of the motor.

Railways and Appliances:—

CONDUIT RAILWAY SYSTEM. O. A. Enholm, New York, 555,937. Filed June 15, 1895.

Employs yokes having traverse arms adapted to receive the rails, and laterally arranged plates in line with the conduit openings.

TRAVELING CONTACT DEVICE. M. D. Law, Washington, D. C., 555,958. Filed Sept. 28, 1894.

A trolley wheel, a pivoted arm for supporting the same; said trolley wheel being located vertically above the pivot and springs applied to lift the horizontal part and to maintain in upright position the vertical part of the arm.

UNDERGROUND TROLLEY. M. D. Law, Washington, D. C., 555,959. Filed May 9, 1895.

Relates to further details of the above.

RAIL BOND FOR ELECTRIC RAILWAYS. F. H. Daniels, Worcester, Mass., 556,046. Filed June 26, 1895.

The two terminals, each have a head of cylindrical shape, and are provided with an opening to receive the end of the bond wire or rod, and a cylindrical hollow portion adapted to extend through a hole in the rail, and to receive a drift pin.

ELECTRIC RAILWAY. H. C. Reagan, Jr., Philadelphia, Pa., 556,210. Filed Sept. 6, 1895.

A cable grip having electromagnet and contact devices mounted thereon, a feed-wire, a suitable conduit therefor, and contacts rotatably mounted on said feed-wire, the latter forming an axis for said contacts.

CLOSED CONDUIT ELECTRIC RAILWAY. E. R. Osmond, New York, 556,311. Filed Oct. 18, 1893.

Details relating to a switch for closing contact to the car circuit.

ELECTRIC SNOW PLOW. H. H. Kryger, Minneapolis, Minn., 556,315. Filed Sept. 10, 1891.

Details of construction adapting the same to be attached to a car.

ELECTRIC RAILWAY. E. M. Boynton, West Newbury, Mass., 556,320. Filed March 6, 1895.

Relates to the Boynton single-rail system with polyphase driving motor.

ELECTRIC UNDERGROUND TROLLEY RAILROAD. G. D. Burton, Boston, Mass., 556,321. Filed Dec. 21, 1895.

Relates to the handling of the trolley pole.

ELECTRIC RAILWAY. R. M. Hunter, Philadelphia, Pa., 556,322. Filed July 19, 1886.

A collector frame suspended from the axis of the vehicle and adapted to have lateral movement, traverse guides to prevent said frame from having longitudinal movement, a collector suspended from said frame, passing through the slot and making contact with the working conductor, and a conductor extending from the collector to the motor.

Switches, Cut-Outs, etc.

INSULATING SUPPORT FOR BOXES CONTAINING ELECTRICAL APPARATUS. T. H. Brady, New Britain, Conn., 555,922. Filed Jan. 4, 1896.

An insulated cut-out box. For description see "The Electrical Engineer," Feb. 19, 1896.

CIRCUIT BLOCK. D. A. Schutt, Peru, Ind., 556,028. Filed Nov. 16, 1895.

Consists of two or more sections of insulating material secured together by one or more metallic connections attached to each section, such metallic connections having electrical connection with main feed and branch wires, respectively.

SNAP SWITCH. A. B. Herrick, Bayonne, N. J., 556,185. Filed Nov. 23, 1895.

A main pivoted current carrying blade and co-operating contacts, a separated pivoted snap blade, beside the main blade in a different plane, and co-operating contact parts or surfaces for the snap blade out of the range of the main blade, and a spring connection between the main and snap blades.

ELECTRIC SWITCH. T. W. Gabel, Lancaster, Pa., 556,264. Filed May 13, 1895.

Adapted to dental work.

Telegraphs:—

INDIVIDUAL CALL SYSTEM FOR AUTOGRAPHIC TELEGRAPHS. H. Etheridge, Pittsburg, Pa., 555,938. Filed Feb. 1, 1892.

Consists of a revoluble shaft, a magnet co-operating therewith, and a clockwork mechanism connected to the paper feed-roll.

Telephones:—

SELECTING AND OPERATING TELEPHONES. H. L. Webb, New York, 555,984. Filed March 18, 1893.

A system of selective calling by varying impulses sent over the line.

AUTOMATIC TELEPHONE EXCHANGE SYSTEM. M. Freudenberg, Paris, France, 556,007. Filed Jan. 10, 1896.

The connections are made by travelers or carriages.

TELEPHONE SPEAKING TUBE SYSTEM. J. S. Stone, Boston, Mass., and G. K. Thompson, Malden, Mass., 556,034. Filed Sept. 28, 1895.

The several circuits, consisting of twisted pairs, are led through the several stations and normally open branches are led to terminals on the switching device at each station.

OBITUARY.

NATHANIEL W. PRATT.

Mr. Nathaniel W. Pratt, well known as an engineer and inventor, died on March 10 at his home in Brooklyn. He was born in Baltimore in 1852. His ancestors settled in Plymouth County, Mass., in 1630. The qualifications that made him a marked man in the world of mechanics were inherited from his father, William Pratt, who was a prominent engineer during the war.

Mr. Pratt was at one time consulting engineer to the Dynamite Gun Company, and from his designs and patents the first successful dynamite gun was built. It was with this gun that the first experiments in throwing aerial torpedoes were conducted at Fort Lafayette, New York Bay.

At the time of his death he was President of the Babcock & Wilcox Company, and a member of the American Society of Mechanical Engineers, American Institute of Mining Engineers, American Naval Institute, and the Engineers' Club, of New York City. His relations with the Babcock & Wilcox Company were always close, and his management of that large business was active and personal.

Mr. Pratt leaves an aged father and mother, a wife and three children.

Reports of Companies.

A PATENT LICENSING ARRANGEMENT BETWEEN THE WESTINGHOUSE AND GENERAL ELECTRIC COMPANIES.

THE subjoined announcement is made with regard to an agreement effected on March 12 in this city between the General Electric and Westinghouse Companies, as to the use of each other's patents:

"Negotiations between the General Electric Company and the Westinghouse Electric and Manufacturing Company have resulted in an arrangement with respect to a joint use of the patents of the two companies, subject to existing licenses, on terms which are considered mutually advantageous.

"It has been agreed that after certain exclusions the General Electric Company has contribtued 62½ per cent. and the Westinghouse Electric and Manufacturing Co. 37½ per cent. in value of the combined patents, and each company is licensed to use the patents of the other company, except as to the matters excluded, each paying a royalty for any use of the combined patents in excess of the value of its contribution to the patents.

"The patents are to be managed by a board of control, consisting of five members, two appointed by each company, and a fifth elected by the four so appointed. Both companies have acquired during their existence a large number of valuable patents and numerous suits have been instituted in consequence of the infringement of these patents by one party or the other, or by their customers. In the prosecution of these suits large sums of money have been expended and the general expenses of the companies have in this manner been greatly increased. It is expected that the economies to be effected will be very considerable and that the two companies and their customers will be mutually protected.

"The especial incentives which led to the arrangement at this time were the recent decisions in favor of patents of the General Electric Company controlling the overhead system of electric railways, the approaching trials on a number of other important General Electric patents on controllers and details of electric railway apparatus and systems and other electricial devices, and the equally strong position of the Westinghouse Company in respect to power transmission, covered by the patents of Nikola Tesla, and in view of its other patents in active litigation, some of which are of controlling importance."

It will be remembered that similar negotiations were begun many months ago, were denied, broken off, and apparently dropped. That steps to effect such a policy were being taken, however, was understood to be the fact, and rumors were current that auhorized discussion of the subject had begun.

Duer, Strong & Jarvis, of No. 50 Wall street, have advertised for stockholders of the General Electric Company, who are not satisfied with the management of President Coffin to confer with them. It is reported that the action is instigated by stockholders of the old Edison General Electric Company, which was absorbed by the General Electric Company.

The General Electric Company was organized April 15, 1892, under the laws of New York, and acquired all of the stocks of the Edison Electric Light, the Edison General Electric, Thomson-Houston Electric and the Thomson-Houston International Electric companies. The total authorized capital stock is $50,000,000, of which $34,712,000 has been issued, $30,460,000 of which is common, and $4,252,000 preferred stock. There are $8,750,000 5 per cent. debenture bonds outstanding. The company paid dividends until August, 1893. No dividends have been paid since that time. Money is said to be in hand to pay a dividend on the preferred stock. The company owns manufacturing plants in Lynn, Mass., and Schenectady, N. Y.

The Westinghouse Electric and Manufacturing Company was organized under the laws of Pennsylvania in 1891. It owns a factory plant near the City of Pittsburg, Pa., and operates, under various agreements, the factories of the United States Electric Lighting Company at Newark, N. J., and of the Consolidated Electric Light Company in this city in the name of the Sawyer-Mann Electric Company. The capital stock is $10,000,000, of which $9,852,300 is preferred and $147,700 common stock outstanding.

The men employed directly by these two companies number about 12,000.

With regard to the effect on Wall street, the New York "Journal" of March 13 tells the following yarn: "While the directors of the two companies were in session yesterday afternoon a scoop was engineered in order to let in a number of outsiders who had not been informed of the certain success of the deal. The stock was broken from 38 to 36¼ in a few minutes on a report that the meeting of the Westinghouse directors had broken up in a row and all negotiations were off. Traders and outside speculators were frightened and threw overboard their holdings in the belief that the deal was off. Nearly 15,000 shares of stock were in this way liquidated by deluded holders and promptly grabbed by brokers for the insiders. So heavy was this liquidation that even the extraordinary buying demand only advanced the stock 1⅛ per cent. to 37⅜, at which price the stock closed. This was a net decline of ⅛ per cent. for the day. After the close of the market the speculators who had been scared out of their holdings discovered their error, and there was a scouring of offices to secure the stock. Before 4 o'clock the stock was 38½ bid on the curb, but few offers were made under 40, and it was doubtful whether 5,000 shares could be secured at that price."

THE AMERICAN ELECTRIC HEATING CORPORATION. —A NEW CONSOLIDATION.

After six months of negotiation the absorption of all the important electric heating companies has been effected by the American Electric Heating Corporation, head office at Sears Building, Boston, and the control of the new consolidation will pass into the hands of a syndicate including Charles A. Morss, Wm. Endicott, Jr., Charles E. Perkins, Charles J. Paine, Oliver Ames, E. S. Converse, C. C. Converse, E. L. Corning, Thomas Nelson, E. N. Fenno, A. R. Whittier, Jackson & Curtis, E. D. Barbour, Robert Bradley, Peter Bradley, Robert Treat Paine, Jr., and others.

The new Board of Directors will consist of J. Murray Forbes, President; Charles A. Morss, Jr., Edward C. Perkins; Charles L. Edgar, of the Edison Electric Light Company; Charles Francis Adams, 2d; Everett Morss, Arthur B. Smith, Geo. U. Crocker, Ambrose Eastman, of Boston; S. S. Wheeler, of the Crocker-Wheeler Electric Company, and Arthur M. Dodge, of New York, and H. B. Scott, of Burlington, Iowa.

The concerns absorbed by the American Company are: The Western Electric Heating Company, St. Paul, Minn.; the Central Electric Heating Company, of New York; the New England Electric Heating Company, the Burton Electric Company, Richmond, Va.; the Carpenter Electric Heating Manufacturing Company, St. Paul, Minn.; the Dewey Electric Heating Company, Syracuse, N. Y.; the Rich Electric Heating Company, Mount Vernon, N. Y., as well as several others which have not been active in the business for some time, but which owned valuable patents.

Heating by electricity is now a commercial success, and in addition to the large number of patents now owned by the American corporation it also owns patents covering the enamel process, which has already proved of great value in rheostats, and it is believed will be of equal importance in many other devices.

The opportunity for the application of electric heating in industrial establishments is very large, and recognizing this, the company has established a laboratory for special work, which will enable it to care for this class of business in an intelligent and satisfactory manner. The line of cooking devices now on the market, as well as other domestic appliances, such as small stoves, laundry and tailors' irons, etc., is quite complete, and a considerable business is being done. During the past season many thousand car heaters were sold by the company. While much of the product has been very satisfactory, that which is not so will receive immediate attention, and several improvements are in hand which will prove to be desirable additions. This especially applies to cooking apparatus, car heaters and special industrial devices.

The slow progress heretofore made in electric heating has not been owing so much to difficulty in perfecting devices as to want of concentration of patent rights and management, and to insufficient capital. The policy of this company is to furnish the best that the state of the art will permit, and they are provided with an able corps of practical men to insure this. They begin business with ample capital and with a list of stockholders and a Board of Directors, composed of substantial and conservative business men, and including some of the foremost electrical engineers in the country.

The manufacturing will be concentrated at Cambridge port, and the head office is at 611 Sears Building, with agencies in New York and Chicago. Mr. James I. Ayer, ex-President of the National Electric Light Association, is the General Manager.

THE PADUCAH ELECTRIC COMPANY, Paducah, Ky., is in the market for a water tube boiler of 150 to 250-horse-power capacity.

LEGAL NOTES.

IMPORTANT DECISION IN FAVOR OF STIERINGER AS TO COMBINATION FIXTURES.

GEORGE MAITLAND VS. ARCHER & PANCOAST CO.—U. S. CIRCUIT COURT, SOUTHERN DIST. N. Y.

THIS was a final hearing in equity before Judge Coxe. The action is founded on Reissued Leters Patent, No. 11,478 granted March 12, 1895, to Luther Stieringer, assignor to complainant, for an improvement in electrical fixtures. The original, No. 259,235, was dated June 6, 1882, and was applied for March 15, 1882.

Claims 1, 7, 8, and 9 of the original were before the court in the Eastern District of Pennsylvania in Maitland vs. Gibson, 63 Fed. Rep., 126, and were held to be invalid.

The decision of the Circuit Court was affirmed by the Circuit Court of Appeals for the Third Circuit upon the opinion of the Circuit Judge (Id., 840).

The first claim of the or.ginal patent was as follows: "A fixture for electric lights, supported from the piping of a house, and electrically insulated therefrom, substantially as set forth." The court held that this claim contained three elements. First, a fixture for electric lights; second, the piping of a house, and, third, means for electrically insulating the fixtures from the piping. That the third element included every kind of insulating device by which two conducting bodies may be mechanically united and yet electrically separated, and that the claim was too broad, and therefore void. Claims 7, 8, and 9 were held to be subsidiary and void, as mere aggregations plainly obvious to the skilled workman.

The complainant construed the decision as awarding him the insulating joint if limited to the precise combination shown, and upon this theory applied for the reissue. So far as relates to the present controversy, the object of the patentee, as stated in the specification, was to utilize the support afforded by the gas pipe of a house for sustaining metallic fixtures for electric lighting containing insulating conducting wires so arranged that the proper connections can be cheaply and conveniently made. He accomplishes this object by carrying the conducting wire from the ceiling, by proper connections, down through the main stem and arms of the chandelier, which may be used also for gas lighting, and is provided with two or more arms and an ornamental shell which hides the wires and connections from view. At the upper end of the chandelier is an insulated joint which separates the chandelier electrically from the grounded piping of the house. The electrical insulation of the fixture from the supporting pipe is as applicable to wall brackets as to chandeliers.

In the course of his decision, Judge Coxe says: A study of this record has convinced me that Stieringer was the first to make the use of gas chandeliers a practical success in the art of electric lighting. The prior structures were not only dangerous, but awkward and ungainly. Stieringer's is absolutely safe, and, at the same time, the symmetry and graceful contour of the fixture is preserved. When the conditions surrounding the genesis of electric lighting are remembered it can hardly be denied that the man who yoked the new art to the old, and fully developed the art of electric lighting was something more than a mechanic.

It is plain that he who utilized for electric lighting the expensive and intricate gas pipe systems then existing and the fixtures which embodied a multitude of graceful designs took a long forward step. He made electric lighting cheap, convenient, simple, and safe. Of course it is not pretended that Stieringer was the first to use gas piping and fixtures in this art, but it is thought that he was the first to make the use of an internally wired metal fixture absolutely safe. If any one did this before Stieringer the record does not disclose his name.

The defendant hardly does justice to Stieringer's achievement when it is asserted that it involved merely the uses of an insulating joint. Grant that with the idea of putting insulation at the ceiling joint of an internally wired fixture clearly before him, it required nothing but ordinary skill for the workmen to carry out the idea, can it be said that it required no exercise of the inventive faculties to conceive and carry out the idea? A number of accomplished inventors were at work on this very problem. They accomplished nothing. Stieringer succeeded. His combination is in use to-day precisely as he embodied it. There have been some incidental mechanical changes, but the substance is the same. It is not an unreasonable presumption that one who succeeds in doing what so accomplished an inventor as Edison failed to do, is on a distinctly higher plane than a mechanic. Not only did Edison fail himself, but he was among the first to recognize the merits of the invention practically as well as theoretically, for his firm took a license under Stieringer's patent. So did the defendant in the Pennsylvania case, the defendant in this case, and afterwards, substantially, the entire art. The importance of the patent was conceded and acquiescence was well-nigh universal.

All this is wholly inconsistent with the theory that the patentee's contribution was perfectly obvious and without patentable merit. The history of the art from 1882 is a refutation of this proposition. Stieringer's joint, located at the ceiling, seems to be regarded as one of the absolutely essential features where an internally wired metal fixture is used. If not essential, why should the defendant and all other manufacturers be so strenuous about its use? They can omit it, or locate it elsewhere in the system with perfect impunity.

It is not pretended that any of the prior patents anticipates; many of them, though relating generally to electric lighting, do not deal with the heavy and dangerous currents from the dynamo, but with feeble currents in branches of the art entirely distinct from the one now under consideration. Aggregated they would not show a skilled workman how to utilize the existing gas fixture.

The ferryboat exhibit is unquestionably the best of the defendant's references.

Irrespective of the question whether it was prior to the conception of Stieringer's invention, and of this there is grave doubt, it is thought that it can only be regarded in the light of an experiment that was tried, proved to be an utter failure, and was abandoned.

If his had been the only contribution to the art, electric lighting, in the particulars mentioned, would not have advanced a step. It was dangerous and inefficient. It accomplished nothing. After a trial of two or three months it was abandoned. During this time the joints leaked gas and broke in two. The chandelier was held by the wires alone, and was in danger of dropping on the heads of the passengers. Some of the very dangers which Stieringer sought to avoid were inherent in this structure.

Perhaps its principal vice was the employment of the metal of the chandelier as part of the conducting circuit. It was a one-wire system. The witness who wired the fixture and who was then a machinist and is now a butcher, describes it fully and accurately. He says, among other things, that it was wired "partly inside and partly out. One wire was inside from the ball joint at the top, the ground wire was soldered onto the pipe; it came through the upper deck overhead and was soldered just below the insulating joint, and that ended it. The other wire ran alongside the pipe and inside the casing from the wooden canopy down to this other wooden ball and then out through and around the wooden ball and then the branch wires were soldered onto the main wire down to the lamp." It is not surprising that such a structure was a complete illustration of "how not to do it." It was an embodiment of irredeemable inefficiency. Short circuits were formed, a wire would ground on the gas pipe and the lights would go out. The pipe was burned, a hole was burned through the brass canopy, the wires were burned off in the tubing and the joints were wholly inadequate. The structure proved an utter failure; the joints were discarded and the wires placed on the outside.

A meritorious invention should not be defeated upon such proof. In fact, the ferryboat fixture is an indirect tribute to the value of Stieringer's invention. It exhibits the kind of work to be expected of a skilled mechanic, even after the insulating joints were placed in his hands. The mechanic failed. The inventor succeeded. In short, I cannot resist the conclusion that Stieringer made an invention of considerable merit, and, this being so, the court, of course, is anxious to give him protection commensurate with his achievement. To confine the invention to some specific form of joint is, as before stated, tantamount to saying that the inventor has done nothing at all. He was not working to improve an insulating joint. He was working to improve the art of electric lighting by cutting off electrically the piping of the ceiling from the metal of the chandelier. To do this he required an insulating joint, to be sure, but it was only one of the elements which, when inserted at the ceiling, made the combination successful. It was this conception which made the valuable contribution to the art. The shops might have been full for years of joints of this character and the art would not have progressed a step. What did advance the art was placing a joint having these characteristics at the ceiling in the manner described. When that was done a combination was created where every element acts upon every other and all are necessary to produce the desired result; in short, a combination having the "per my et per tout" characteristics.

The only other question relates to the reissue. Still confining the discussion to the first claim it seems too plain for ar-

gument that it is much narrower than the first claim of the original. None of the limitations above referred to is in the latter. The claim of the reissue is fully sustained by the original specification and drawings. As soon as the complainant was informed by the final decision of the court that his claim was too broad he applied for a reissue limiting it to what he thought the court had left in his possession. Of course, no structure would infringe the claim under consideration that would not infringe the broad claim of the original, and no intervening equities have arisen. In such circumstances I know of no authority compelling a ruling that the reissue is void.

It follows that as to the first claim of the reissue the complainant is entitled to the usual decree.

In this case Hector T. Fenton appeared for the defendant and R. N. Dyer and D. H. Driscoll for the complainant.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE IRON CLAD RHEOSTATS.

One of the essential adjuncts to every electric generating or motor plant is the regulating apparatus, and among this the rheostat plays a most important part. The improvements which have been effected in this detail during the last few

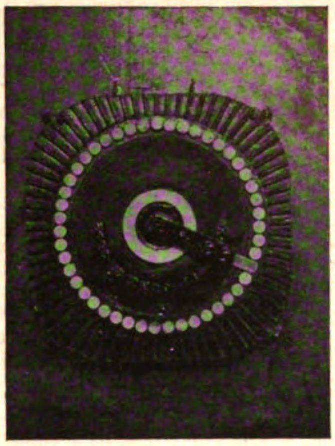


FIG. 1.

FIG. 2.

years have been most striking and resulted not only in increased efficiency and reduction in space required, but in cost as well. Among this class of apparatus the "iron clad" rheostat, manufactured by the Iron Clad Rheostat Company, of Westfield, N. J., has steadily increased in use, and the new

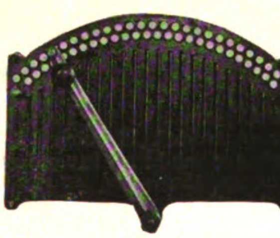

FIG. 3.

price list embodied in the company's advertisement in this issue indicates the extent and variety of their work. We illustrate herewith a few of their more prominent products.

Fig. 1 illustrates a field rheostat arranged to be mounted on the rear of the switchboard; Fig. 2 shows it in side elevation; the same plates are furnished for mounting on the face of the switchboard, one of this type being shown in Fig. 3.

Among the variety of motor starting and motor regulating rheostats we illustrate those shown in Figs. 4 and 5.

The Iron Clad Rheostat Company manufacture a most complete line of these rheostats, and also make a specialty of building feeder equalizers, regulators to be used in connection with storage batteries, special instruments for the use of surgeons and dentists for cautery work, and also rheostats to be used in connection with galvanic, and faradic batteries.

These rheostats are made on the well-known principle of using a large metal surface for radiating the power dissipated in small resistance conductors. The conductors are imbedded in an insulating material attached to the cast iron plate.

The process by which these rheostats are made allows for

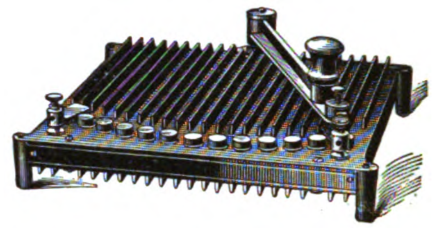

FIG. 4.

the difference in expansion in the materials used without danger of disintegration of the plate.

In September, 1895, the company built a commodious factory

FIG. 5.

at Westfield, N. J., to accommodate their growing business, and since then their business has so increased that they are now discussing an extension to the factory.

THE WIRING OF ELECTRIC CARS.

The Interior Conduit and Insulation Company has just issued a circular to street railway companies, of which we print the body below:

We take the liberty of addressing you upon the subject of the Wiring of Railroad Cars for electric lighting and power. The system we are promoting relieves you from all the annoyance, discredit and dangers attendant upon the past methods of wiring, and instantly commends itself to railroad companies, car builders and electrical engineers on account of its simplicity, durability and economy. Our method consists of a system of insulating waterproof and electrically fireproof tubes which may be concealed in the framework of cars after the manner of gaspipes. These tubes are run from roof of car to motors, controllers and all lamp outlets in the car, thus making a complete insulated raceway for all wires. The dangers resulting from the accidental overheating, or perhaps melting of wires, and the consequent liability to destruction from fire, is completely eliminated by the use of our system. The wires are perfectly accessible at all times, and in the event of the failure of any circuit from any electrical derangement the defective wire may be withdrawn and a new one substituted in its place without removing the woodwork or defacing the interior finish of car. The system we offer you insures absolute immunity from fire, accessibility to concealed wires, durability of insulation, reliability and economy. We manufacture insulating conduits, protected by either brass or iron armor, and mail you samples of both under separate cover.

THE BIMETALLIC ELECTRIC TRANSMISSION COMPANY, 1204 Havemeyer Building, has issued a neat circular on its specialty, the front and back covers being printed in bronze, so as to show the steel core in its copper sheath. There is a loose sheet giving sizes, weights and strengths, and the text describes the various uses in each branch of electricity, to which the bimetallic wire can be advantageously put. The wire is beautifully made—a choice example of the wiredrawer's highest art.

MR. THOMAS R. TALTAVALL, who for the past six years has been editor and part owner of the "Electrical Age" of this city, has sold out his interest in that journal and resigned as its editor, his resignation taking effect last Saturday.

PROFESSOR ROENTGEN has been created a baron of the Kingdom of Bavaria, in which State the University of Wurzburg is situated.

Department News Items will be found in advertising pages.

ELECTRIC LIGHTING.

EXPERIMENTS WITH ROENTGEN RAYS.

BY

Thomas A. Edison.

WELL crystallized tungstate of calcium made by the fusion process is extremely sensitive to the Röntgen ray. If the ray varies as the square of the distance, as there is every experimental reason to think it does, the tungsten salt is six times more sensitive to the ray than platino-barium cyanide. Plates of hard calendered pasteboard covered with the crystals permit, with a good tube, the seeing of all of the bones of the hand and arm. The fingers can be seen moving through eight inches of wood.

The next best fluorescing salt is tungstate of strontium, made in the same manner. Tungstate of barium or lead does not appreciably fluoresce. Knowing that the ray is absorbed by metals of great atomic weight, it would be natural to suppose the tungsten salts would fluoresce, and that it would be necessary to use a salt of a heavy metal, or one of great atomic complexity, but this is not true, as salicylate of ammonia crystals fluoresce with about the same power as platino-barium cyanide. The salicylate of ammonia crystals have this peculiarity that the fluorescence increases when the plate is covered more thickly with crystals, the maximum sensitiveness is reached when looking through ¼ of an inch of loose crystals. This would show high fluorescent power with low absorption.

There are a number of other salts and minerals which fluoresce. The following is a list: Subchloride of mercury, mercury diphenyl, cadmium iodide, sulphide calcium, potassium bromide, tetrametaphosphate of lead, potassium iodide, mercurous chloride, bromide lead, sulphate lead, fluorite, powdered lead glass, pectolite, sodium cressotinate, ammonia salicylate, calcium salicylate, salicylic acid.

The following are salts which fluoresce less: Powdered German glass, barium fluoride, calcium fluoride, sodium fluoride, sodium chloride, mercuric chloride, cadmium chloride, silver chloride, lead chloride, lead iodide, sodium bromide, cadmium, lithia bromide, mercury, cadium sulphate, uranium sulphate, uranium phosphate, uranium nitrate, uranium acetate, molybdic acid, silicate of potash dry, sodium bromide, wulfenite, orthoclase andalucite, herdinite, pyromorphite, apatite, calcite, danburite, calcium carbonate, strontium acetate, sodium tartrate, barium sulphobenzoic, calcium iodide, true and artificial ammonium benzoic.

It is anomalous that rock salt being practically transparent to radiant light and heat, should powerfully absorb the X-ray and give strong fluorescence.

I have found with a thick cube of fluorite, which is transparent like glass, that it fluoresces strongly to the ray, and accumulates, getting brighter and brighter; after the bulb is disconnected it continues to fluoresce for several minutes. I have not noticed this in any other substance, except slightly in thick layers of calcium tungstate. If the hand is held before a box containing the fluorite plate, the shadow of the same may be seen phosphorescing for a minute or two after the current has been disconnected from the tube.

A curious phenomenon occurs in tubes which are best adopted for the X-ray. After obtaining a high vacuum on the pump, where the line spectrum disappears and pure fluorescence and the X-ray is strongest, the lamp is sealed off. In a short time, varying with the different lamps from one to three hours, the vacuum becomes poor. All the phenomena of low vacuum take place in light and the vacuum is really low, as ascertained by experiments while on the pump. If now the tube be kept in connection with the current it will gradually go through all the changes to a high vacuum, the line spectrum will disappear suddenly and X-rays will appear. If the bulb be left for 24 hours it requires 4½ hours continuous connection with the current to bring it back to the X-ray stage. Eighty per cent. of the lamps act in this manner; it is independent of the kind of glass and of many variations made in the pump; it occurs with, or without, phosphoric anhydride. It would seem that the effect was due to atomic electrolysis, free atoms being disconnected with the ether, only molecules being connected so as to produce pressure on the walls of the tube.

Another experiment in connection with vacuum tubes is worth recording. Edlund's theory, which has not yet been refuted experimentally, is that a vacuum is a perfect conductor of electricity. As it has been found that the resistance of any tube but slightly changes when the distance between the electrodes is increased and that the whole of the resistance is at the electrodes; also that when the vacuum is so high that no spark can be forced through it, it is easily made luminous by external electrodes, there being none in the glass. In the course of my experiments I obtained a very high vacuum through which a 12-inch spark with Leyden jars could not be forced; neither could any conduction take place with external electrodes. The tube was always dark.

It has been stated that aluminum and magnesium electrodes do not deposit on the glass. In the case of magnesium, by several hours' sparking there is formed a magnesium mirror, of lavender color by transmitted light. In the case of aluminum there is apparently no deposit. Mr. Dally, my glassblower, by oxidizing the surface of a broken tube found that the layer of aluminum was transparent and only appeared when oxidized to aluminum oxide, which was so thick that objects could not be seen through it.

I am continuing my investigations in this direction.

ROENTGEN RAYS "ANODIC" NOT "CATHODIC."

BY

Elihu Thomson

SINCE the first publications concerning Röntgen's discovery of the rays emanating from a Crookes tube it seems to have been assumed by most investigators that said rays have some relation to the radiant matter of Crookes which is a phenomenon of the cathodic terminal.

Others, again, have considered that the rays discovered by Röntgen were produced at the glass surface, or during transmission through the glass and as a consequence of the impingement of the cathode rays upon the glass, causing its fluorescence. Professor J. J. Thomson is reported to have exposed photographic plates to the cathode rays or radiant matter within the tube without having produced any effect which could be brought out by development.

Very recently Professor H. A. Rowland has pointed out the fact that the Röntgen rays are emitted from the anode and not from the cathode, and this view, coming from so high an authority, is in itself an indication of its probable truth. The writer, personally, had been led to suspect that the rays were anodic, not cathodic; for it was found that the rays when traced to their source within the tube by methods which have been published by him, came from that terminal which, during the passage of the spark discharges, could not have been the cathode. Using a Wimshurst machine, it was easy to determine the polarities. Furthermore, the best effects on the photographic plates were produced opposite that portion of the glass which became strongly fluorescent. This fluorescence, however, could not have been produced from the cathode, as the rays normal to the cathode surface would not have impinged there.

By constructing a dark tube with a screen of barium platino-

cyanide the writer was able to submit to examination the various forms of Crookes tubes in his possession. Some of these, though fluorescing strongly by the cathode rays, gave at no position with respect to the screen tube any indications of the emission of Röntgen rays, while some gave feeble indications near the anode, and in exceptional instances a strong effect was noted, not from those parts where the cathode rays made the glass fluorescent, but from other parts opposite the anode.

The crucial test was made by placing a small patch of opaque metal upon the side of a tube opposite the anode. It was found that when the anode, the patch, and the fluorescent screen were in line, no fluorescence was obtained, although the screen was fully exposed, as it were, to the cathode.

It may be mentioned here that the fluorescent screen tube forms a most valuable means for rapidly exploring the fielu of the Crookes tube and so determining whether it can be used as a source of Röntgen rays or not. It also enables one to determine the best direction in which the rays are emitted and is much quicker than the sensitive plate for such observations.

In one of the tubes examined the effects appeared to indicate that the Röntgen or anode rays are deflected or turned aside sharply when they arrive near the cathode terminal, which in this case was a bent sheet of aluminum. This effect is worthy of further investigation.

The writer also personally exhausted a Crookes tube by a Sprengel pump, watching with the fluorescent screen tube for the first indications of Röntgen rays. It was found that when that degree of exhaustion was reached which gave an excellent exhibition of radiant matter from the cathode, and even clear-cut shadows of objects by such rays as evidenced by the brilliant fluorescence of the glass where the rays impinged, there still was no indication of Röntgen rays, even when the fluorescent screen in its dark tube was not more than a quarter of an inch from the strongly fluorescing glass wall. As, however, the exhaustion improved, the indications of Röntgen rays began to be manifest, and at last they became quite pronounced. These rays seem to originate at the anode and, although they may possibly be deflected in the vicinity of the cathode, they otherwise proceed in straight lines from the anode and through the glass, causing fluorescence of the latter in much the same way to all appearances as the cathode rays, except that while the cathode ray fluorescence is fairly stable or stationary, the anode ray fluorescence flits about or changes its direction with every discharge, scarcely, if ever, repeating the same pattern of fluorescent patches on the walls of the tube or bulb.

The following summary of effects is apparently in accord with the facts:

1. Cathode rays are produced at lower exhaustions than give rise to anode rays that reach the glass.
2. Anode rays are best produced at the high exhaustions short of insulation.
3. Anode rays pass out through the glass of the Crookes tube; cathode rays (radiant matter) apparently do not.
4. Both anode and cathode rays cause fluorescence of the glass and possibly of many other substances. It is not known whether anode rays cause fluorescence of any substances that are not so affected by cathode rays, and vice versa.
5. Anode rays are erratic in distribution from the anode surface. Cathode rays are of nearly uniform distribution, and leave the cathode surface at right angles.
6. Anode rays are not capable of being deflected by a magnet; at least not after they have passed the glass. Cathode rays appear to be so deflected within the tube and after they have traversed an aluminum window. (Lenard).
7. Diminishing the size of the anode concentrates and focalizes the rays emanating therefrom. Shaping the cathode into a concave cup gives rise to a focus of cathode rays by virtue of their direction being normal to the cathode surface.

The question suggests itself, Can anode rays reach and pass through a thin aluminum sheet which is at the same moment the cathode for the discharge? And, on the other hand, Can cathode rays traverse the anode if of thin aluminum sheet? It is probable that opacity of the opposite terminal would be noted in these cases, and, possibly, deflection of the rays in each case near the terminal of opposite polarity to that emitting the rays.

The significance of Röntgen's discovery is greatly enhanced and the scientific interest therein multiplied when it is recognized that there may be an entirely unsuspected radiation, not from the cathode but from the anode; that both electrodes may emit radiations characteristic of the electric states of the terminals, and that such radiations are widely different from each other and from other known radiations. If the anode rays are longitudinal waves in the ether, what are the cathode rays? If the cathode rays are longitudinal what are those of the anode? Is it possible that neither of them are longitudinal vibrations of the ether and that one must now look for an explanation of the two radiations which shall be alike, and yet not alike?

In these radiations there may be again a manifestation of differences between positive and negative electrical states which differences seem to be in some way impressed on the radiations set up in the neighborhood of the poles. There undoubtedly is a great field for research opened by the discovery of Röntgen, and it is fortunate for science that the Crookes tube he experimented with possessed a high enough vacuum to cause it to give anodic as well as cathodic rays.

THE SPECTRA OF THE BUNSEN BURNER AND EXHAUSTED BULBS.

BY DR. W. H. BIRCHMORE.

THERE are few things more remarkable in the present widespread study of the ether vibrations started in Crookes or other exhausted tubes than the indifference to scientific data which has been shown in the published accounts of results. The unconscionable vagaries of light are well known to all students, but this light, more than any other, counts of results. The unconscionable vagaries of light are displayed by the exhausted bulbs, for no two in my experience give the same hue, caused me to institute comparisons among the spectra. The results of some of these I have compared on paper and they form the basis of this essay. That the volume of data is not larger must be credited partly to the enormous amount of labor involved and partly to a desire to set others, who may be so situated that they can pursue the study, on the track of what I consider an interesting investigation before the interest is exhausted.

To encourage the inquiry among those who have the use of instruments they might fear inadequate to undertake such research, I have pursued my studies, those on which this essay

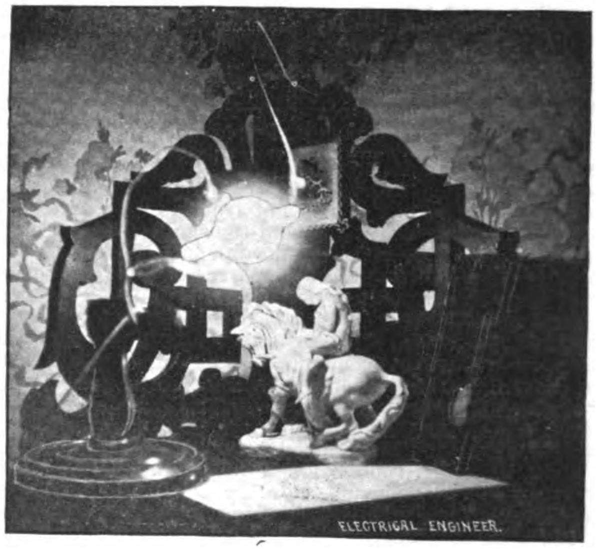

Fig. 1.—CROOKES TUBE PHOTOGRAPH.
(*Copyright, 1896, by W. H. Birchmore.*)

is based, with a comparatively small instrument. The instrument used is the one referred to in my last contribution to hydro-carbon-flame literature[1], and was sufficiently described therein. Any single prism instrument will do for the study and a fortiori any larger one.

Description of the Plate.—To give a ready means of reference the principal Fraunhofer lines on the accompanying plate are shown in No. 1 above the scale. The centesimal scale is the one usually given with small instruments and this is given in line No. 2, while in line No. 3 is the sun spectrum. Great pains have been taken in making choice of the lines shown in this spectrum. My small instrument shows so many that I was in doubt as to the margin between too many and not enough, and I finally concluded to draw in only those found in the ordinary school books, Ganot and the like. In passing it may be well to mention that any one-prism instrument will show about thirty lines when directed against a white wall or cloud on which the sun is shining, and from 400 to 600 when directed against a mirror or the sun itself. An instrument, such as this can be purchased at almost any price between $40 and $100, and one costing about $40 (J. W. Queen & Co.'s

[1] "The Electrical Engineer," March 18, 1896.

"R 55") is quite equal to doing all that any one not specially interested in spectrology can wish to do.

Of the lines shown, D, the sodium line, is the Greenwich meridian for all studies, while E and G are landmarks whose precise significance is still sub judice, but they probably are atmospheric lines. It must always be remembered that lines seemingly single in an instrument of small dispersion often become extensive groups when the dispersion is increased. The D line, for instance, in this instrument shows as a sharply defined line, while with larger instruments it shows as two wide bands and some twenty odd lines.

No. 4, the Bunsen Burner Spectrum.—It is with great sense of the importance of what I am about to do that I approach the discussion of this spectrum. The evidence of its actinic power given by the pictures shown in the last number of this journal is a demonstration of the enormous radiation of "chemical" rays, while the extreme distress of the eyes produced by the same radiation is the subjective evidence of the same fact. This distress is well known to all who in laboratory work have had to watch the working of these flames; for instance, while heating a crucible, the eyes actually seem relieved when the white-hot crucible begins to give off rays which will cause the pupil to close. This is an instance often

covering the flame nearly to the very point, while on the other it extends up less than a third of the way. The Müncke mixes the air infinitely better and gives in every way a better and more rapid and complete combustion. It is but a fair deduction, then, to infer that the gases, both those which burn and those which sustain the combustion, are more nearly at the same temperature throughout than are those of the ordinary Bunsen, and therefore the radiation will have more nearly the same wave length in the waves from the Müncke than from the ordinary burner, and so it is shown by the spectrum to be. In an instrument of sufficient definition and dispersion the band is resolved into a group of infinitely fine lines, showing that there are waves of an infinite variety of lengths, which, combining, form the bands. In other words, the instruments proclaim that in the ordinary Bunsen, the gases are heated so slowly that an appreciable period elapses between the time when they begin to cause undulations, and the instant when they are heated so hot as to combine with the oxygen of the air and to burn.

But the spectrum tells us more; it also says that the gases are heated to a point beyond their temperature of combination, for were this not so the sharp line of each band would be at the end of the shortest waves instead of substantially in the

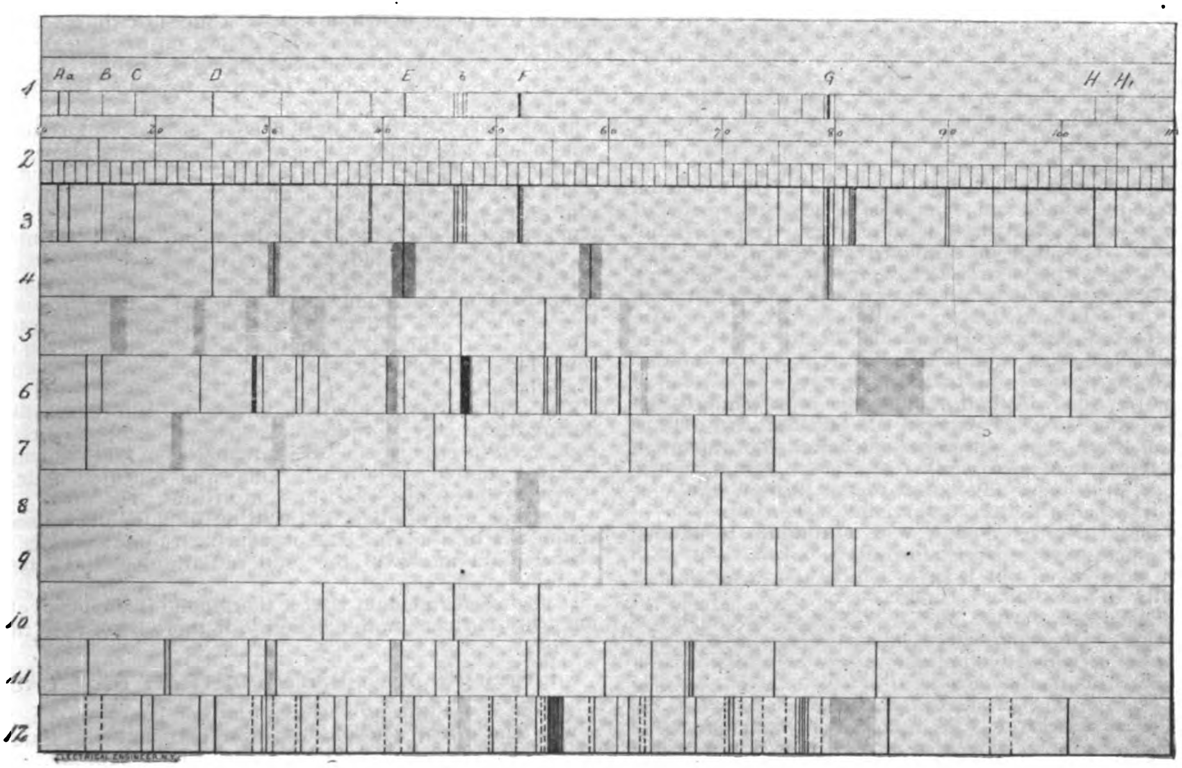

FIG. 2.—LINE SPECTRA OF FLAMES AND VACUUM TUBES.

seen in nature, the pupil closes to the stimulus of light, not actinic or heat rays, and although it will close twenty-five times faster on light rays from the neighborhood of G, than it will for rays from the neighborhood of B, it suffers from the actinic rays while even the G stimulus is too small to affect it.

Two widely different spectra are combined to form the spectrum shown in the plate. One the spectrum from an ordinary Bunsen burner in which the center of the flame is a long green cone, the other the spectrum from the form of Müncke burner, sold by the Welsbach people.

A. The Ordinary Bunsen Burner Spectrum.—This spectrum may be described with sufficient accuracy as being one of four broad bands, and a sodium line.

B. The Müncke-Bunsen Spectrum.—This consists of five sharply defined lines, one the sodium line, two lines in the spectrum answering to 305 and 583; while the other two are substantially identical with E and G of the solar spectrum. This marked difference certainly must strike the attention of every one who sees it, and the more if he happen to superpose the spectra, in which case he finds the bands accurately bisected by the lines, as shown in the drawing. As was mentioned, they differ in no way except the burner used; the difference in the spectrum then must be due to the difference in the physics of the two flames. How, then, do these differ?

If we closely examine the flames we find in one a long green cone, in the other a very short one. One has a violet envelope

middle. Actually, then, the Bunsen burners, as we ordinarily use them, waste no small part of the heat they produce in heating the air and fuel gases beyond any useful limit. This margin of waste, or margin of saving, as we please to call it, explains why the Müncke burner gives a temperature so much higher than that of an ordinary Bunsen. The air and gas are so thoroughly mixed that the green cone of the ordinary burner is only a thin covering to the gauze and heats quickly to the combining temperature, never overheats, and gives a sharp line in the spectrum, and no band.

Line No. 5 is the spectrum of an electric spark passed between two copper terminals, without the introduction of a condenser. No. 6 is the same battery and coil, using another pair of terminals with a condenser in circuit. Where to find the origin of the lines present in No. 5 is indeed a puzzle, for, although they may with sufficient certainty be set down as caused by other metallic elements in the copper, yet so confused a spectrum should not be furnished from a reasonably pure wire by so weak a spark. Here, again, we have the phenomenon of bands, the result of a multitude of waves of about the same length. The three sharply defined lines are one in the green and two in the blue and might be assumed as the blue-green copper lines, but this must be taken with a teaspoonful of salt. In spectrum No. 6 there are many more lines caused by the greater power of the spark, bands are reduced to lines and a new band appears. These changes are interest-

ing, but unsatisfactory; they show how dependent on spark intensity and such small trifles a spectrum may be. For this reason the elements of an experiment should always be given.

The line near D is not D, but a line perhaps corresponding to Kirchof's group of atmospheric lines, which indeed is more than probable in view of the appearance in No. 5.

In No. 6, starting from the left, the first line belongs to potassium; how it came to be in a copper spectrum deponent sayeth not. The next line is one also found in the sun spectrum which Kirchof has not named. The third line, 240 in this spectroscope, is the air group 972-984 in Kirchof's map. The broad band 29 is also an air band, 1,135-1,168, Kirchof. The sharply defined line beside it is the arsenic-antimony group between 1,180 and 1,190 K, a very natural and proper contamination of copper. The next three lines between 320 and 350 are also antimony and arsenic lines. The lines near E are the copper lines of that group, as is also 494; the lines between them belong to magnesium, probably reduced and alloyed from the limestone used in fluxing the copper. A number of additional copper lines follow, until the pair at 580 is reached; these are air lines and play a prominent part in the Bunsen burner spectrum. The group 610-630 are also air lines. This brings us to the group of four lines, 705, 720, 740, 755. Of these 720 is a magnesium line and 755 is a lead line; the other two, like the rest of the spectrum, are not determined in Kirchof's map, and as this is the natural reference list for the larger part of mankind, I have not referred to any other. This spectrum has been given not only for its intrinsic interest, but to emphasize a point which I particularly wish to make, that there are lines recognized and easily recognizable belonging to the components of the atmosphere in which we live and commonly called "air lines."

The Spectra of the Exhausted Bulbs.—No. 7 is the spectrum of a bulb made by Somof and exhausted to less than one-half a millimetre, to what exact limit I cannot say. It is magnificently luminous, of which the annexed engraving, Fig. 2, a photograph taken with its radiation, is proof. The negative pole is a disc of aluminum 20 mm. in diameter, connected with a platinum wire. The anode is a platinum wire. This disc radiates an intense pearl or lavender light by which white can be distinguished from black. Using a weak spark, the distance between the poles is only 22 mm., the spectrum given is the one shown in No. 7. When a condenser is introduced, the spectrum appearing is No. 11; beyond the fact that a few lines are intensified, there is no difference, although the amperage of the current was increased many fold. Here, again, we see the phenomena mentioned in relation to the Bunsen flame, of the non-identity of the actinic and visible spectrum.

No. 8 is a bulb, also, by Somof, with aluminum terminals. No. 9 is one almost exactly like it in design, but of vastly less actinic power than No. 7, but it gives nearly the same colored light, especially if a secondary condenser be used. It should be mentioned that the actinic power of Somof, No. 8, is relatively very low. Of course there was no means at hand by which the degree to which he had exhausted these bulbs could be ascertained, as his method was that of the maker of electric lamps, but a series of experiments has been undertaken by which I expect to ascertain the relations of exhaustion to actinic power by carefully exhausting two lamps of otherwise identical conditions.

No. 10 is a "Buckeye" lamp, with a carbon connected to the positive pole of the coil, and the covering of tinfoil at the top with the negative pole. The lamp acted as a condenser and flashes of lightning ran over it in a most beautiful way. This lamp gave as distinct a fluorescence as any bulb in my possession, while its spectrum is limited to four bright lines, all air.

No. 12 is the spectrum of the arc formed between two aluminum terminals. The lines are those of aluminum and aluminum impurities. The dotted lines show the lines in the copper spectrum which have no corresponding lines in the aluminum one. At the same time the contamination of the aluminum with copper, and copper impurities, as well as with those always found in aluminum, metals of the iron group, and sodium, is distinctly shown. The relations of a number of these lines plainly shows the difference in the temperature of the aluminum and the copper arc, the arc between the copper terminals being very much hotter indeed, as is obviously necessary when the difference in the boiling points of the two metals is considered.

The electrical apparatus used consisted of a zinc-acid-carbon battery, giving a current of ten amperes under five volts pressure; both quantities were measured. This current was sent through a coil having about 0.005 ohm in the primary circuit and 2,000 ohms in the secondary. Under ordinary circumstances this coil gives a 1¾-inch continuous spark. When a condenser is used the spark was reduced in length to ⅜ of an inch; under these circumstances, the spectrum of iron is very finely displayed. This spark has all the sensible features of an arc and is usually so spoken of.

This e. m. f. is far more than is needed to run the bulbs. In fact, with many bulbs, I find a current of ten amperes at 1½ volts is all that is needed to excite the coil, but, of course, this is utterly insufficient in obtaining the spectra of metals.

MERCURY, LAMPBLACK, THERMOPILE AND X-RAYS.

BY I. THORNTON OSMOND.

Mercury, lampblack, and the thermopile are intimately connected with the measurement of radiant energy. All attempts to measure the solar constant have assumed that the energy of solar radiation is either in the form of heat or in some form totally convertible into heat by the apparatus used. For several years (see "The Electrical Engineer," November, 1892, p. 443) I have believed that this assumption needs better evidence before results in any wise dependent on it can be accepted as certainly correct.

On March 10, 1896, I exposed to the X-rays from a Crookes tube actuated by a large inductorium, a paper box filled with pressed lampblack powder about 3 mm. in thickness, a paper box lid (empty), a paper box containing about 3 mm. depth of mercury, a piece of windowglass, a piece of thick sheet aluminum, and a silver quarter of a dollar, on the outside of an ordinary camera plateholder, containing a Carbutt dry plate. All colored paper was carefully removed from the top and bottom of the paper boxes and lids.

The mercury (as in an earlier trial) proved very opaque. The lampblack was highly transparent, apparently absorbing none of the X-rays. On March 16, I placed a paper box filled to a depth of 3 or 4 mm. with lampblack on the face of a thermopile of 49 pairs of bismuth and antimony, and over the lampblack the Crookes tube. The thermopile could be quickly put in circuit, without moving it or the lampblack box, with a highly sensitive mirror galvanometer at some distance. The hand held for a second or two before, but not touching, the thermopile gave a deflection of 25 or 30 mm. The lampblack cut off any heat radiated from the warmed part of the Crookes tube, but transmitted the X-rays, as shown in the experiment of March 10.

The coil was put in action, taking 1,500 to 2,000 discharges during about three minutes. Then the thermopile was quickly connected in circuit with the galvanometer. There was no certainly readable deflection. This was repeated four or five times, at intervals, with the same result.

It seems evident that the coating of lampblack used on instruments in studying and measuring radiant energy will not absorb (and measure) the total radiation, if there be X-rays therein.

It also seems evident that a thermopile (bolometer, etc.) will not truly measure radiant energy, if there be X-rays therein.

LINES ON AN X-RAYS PORTRAIT OF A LADY.

She is so tall, so slender; and her bones—
Those frail phosphates, those carbonates of lime—
Are well produced by cathode rays sublime,
By oscillations, amperes, and by ohms.
Her dorsal vertebrae are not concealed
By epidermis, but are well revealed.

Around her ribs, those beauteous twenty-four,
Her flesh a halo makes, misty in line,
Her noseless, eyeless face looks into mine,
And I but whisper, "Sweetheart, Je t'adore."
Her white and gleaming teeth at me do laugh.
Ah! lovely, cruel, sweet cathodograph!

LAWRENCE K. RUSSELL in "Life."

ROENTGEN RAY EXPERIMENTS.

Mr. Edison is steadily continuing his experiments on Röntgen rays at his laboratory at Orange, N. J., and last week succeeded in making visible metallic objects and the bones of the hand through a block of wood 8 inches thick. These results were accomplished by the use of a phosphorescent screen of tungstate of calcium, placed between the eye and the Röntgen tube. Professor O. N. Rood, of Columbia University, New York, has succeeded in demonstrating by the aid of photography, that a small percentage of the Röntgen rays falling on a platinum mirror at an angle of 45 degrees, is reflected. The bacteriologists of the New York Health Department have been experimenting to determine what effect the Röntgen rays have on the bacilli of tuberculosis and diphtheria. Thus far their results have been negative, the cultures apparently thriving unaffected under the influence.

SHADOW PICTURES BY ARC LIGHT RAYS.

BY W. W. KER.

WHEN a new discovery is announced men immediately set to work to make themselves familiar with its details and make improvements in the process, or endeavor to deter-

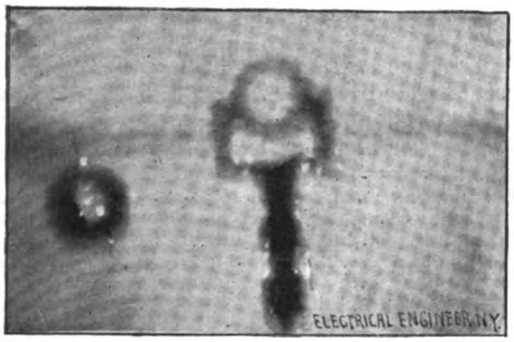

FIG. 1.

mine if the same result can be accomplished by simpler means, and thus add valuable data for the formulation of a theory or to strengthen that which may already exist. So I may be par-

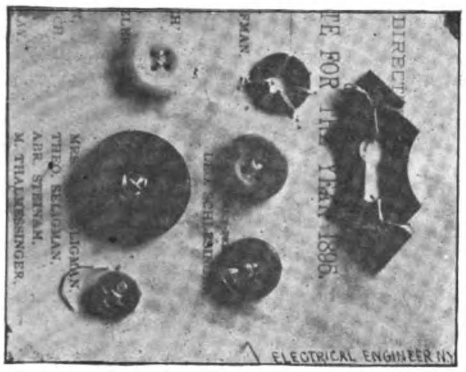

FIG. 2.—PORCELAIN BUTTON. LARGE PEARL BUTTON. SMALL PEARL BUTTON. HARD RUBBER WASHER. BONE BUTTON. IRON BUTTON. BRASS ESCUTCHEON.

doned for encroaching on your valuable space with something of little practical value, but which may add a few facts concerning the production of X-rays by an arc lamp.

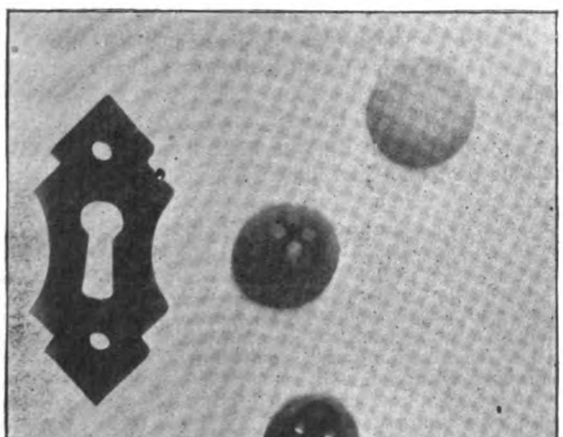

FIG. 3.

The method employed in making the following experiments was to sew the objects to be exposed on a piece of stiff paper and place them on the film side of a slow Seeds dry plate, commonly used for making lantern slides. The negatives and objects were then placed in the plateholder and the pasteboard slide put in position, covering all. The plateholder was then placed about eight inches from the arc lamp, care being taken to prevent the film from melting, due to the heat radiated by the arc. After exposure the plates were developed in the usual manner.

The following plates were made during the week beginning

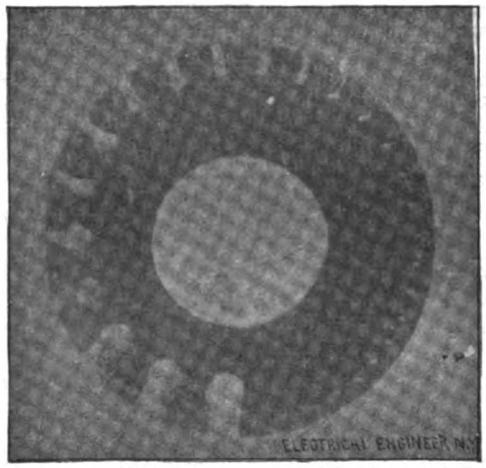

FIG. 4.

Feb. 23, in the electrical laboratory of the Hebrew Technical Institute by the writer, assisted by Mr. S. Hamburger, of the class of '96.

The first plate exposed to the arc was covered with a piece of paper having a brass key tag and a package of sewing needles fastened to it, as described above. The result, after 45 minutes' exposure, showed that the key tag and the paper of needles had shut off the rays, leaving the shadow of the objects very clear and the glass transparent, while the rest of the negative was very black. On examining the plate I concluded that it could not be due to Röntgen rays, because the steel needles did not appear and the black paper had not been penetrated.

The second plate, Fig. 1, represents an iron key and a copper

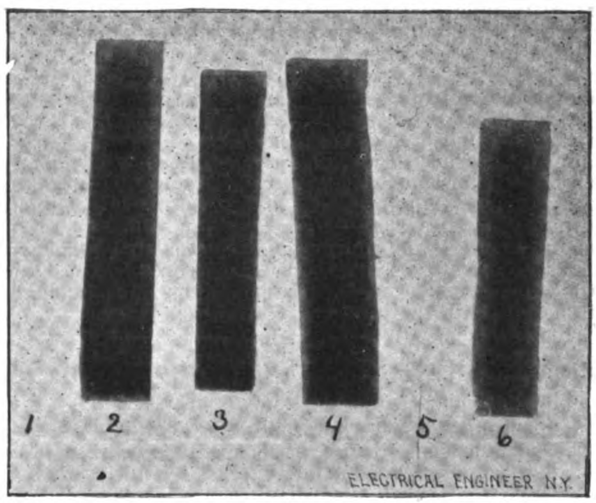

FIG. 5.—CELLULOID STRIPS: NO. 1, YELLOW; NO. 2, DARK BLUE; NO. 3, PINK; NO. 4, BRIGHT BLUE; NO. 5, RED; NO. 6, TRANSPARENT.

washer fastened to a piece of paper, put in the plateholder and exposed to the sun 4½ hours. An examination will show how the paper helped to weaken the rays; the light readily passed through holes made in the paper while sewing on the articles. One notable fact indicated by the time of exposure is that the arc had greater penetrating power than the sun, and it might possess Röntgen or other active rays which the sun did not.

For experiment, No. 3, a number of buttons made of differ-

ent materials, and shown in Fig. 2—which is an ordinary photograph made with a camera by daylight—was placed on a negative and exposed to the arc for 30 minutes and developed in about 20 minutes. It will be seen (Fig. 3) that the brass escutcheon and the metal and bone buttons have stopped the rays completely, the porcelain partially, and the hard rubber washer 1-16 of an inch thick; but the two pearl buttons had no effect whatever in shutting out the active rays.

In my estimation this negative is the result of X-rays or another action and not of ordinary light, as stated by Professor Stine and Mr. W. H. Freedman, in the issue of "The Electrical Engineer" of March 11. If the result had been due to ordinary light, it is fair to assume there would have been some trace of these bodies on the print.

The fourth experiment consisted in making a negative of an ordinary steel wire gauge fastened to a piece of paper, put in the plateholder and placed in a ½-inch pine box. The result

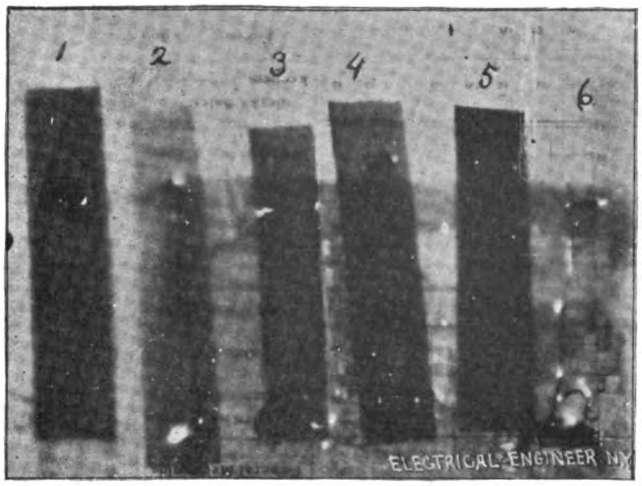

FIG. 6.

of 55 minutes' exposure is shown in Fig. 4. In this case it was necessary for the rays to pass through a ½-inch pine board, the pasteboard slide, and the paper holding the object.

I think the above facts are sufficient to prove that there are X or other rays emanating from the electric arc light.

In order to examine the effect of color by the rays, I fastened a number of colored strips of celluloid to a piece of paper in the usual manner and placed them in the plateholder, which was exposed for 30 minutes, and the result is shown in Fig. 5. The active rays were cut off by the transparent, the two blue and the pink strip; the yellow and red strips, such as are used by photographers to shut out the actinic rays when developing negatives, had allowed the rays to pass without the slightest obstruction, and to act on the plate.

While endeavoring to reproduce the above result under apparently the same conditions, opposite results were obtained, as shown in Fig. 6, and for the first time in my experiments the printing on the paper appeared.

This most interesting phenomenon will be further investigated at the laboratory of Dr. W. J. Morton, who has kindly offered the writer the use of his apparatus for making comparative tests with the vacuum tubes and arc lamp.

EXPERIMENTS WITH INCANDESCENT LAMP AND MAGNETS.

AT a meeting of the Physical Society, held on Feb. 28, Sir D. Salomons showed some experiments with incandescent lamps. A large electromagnet is excited by means of a continuous current, while an alternating current is passed through an incandescent lamp. On bringing the lamp near the magnet the filament is set in vibration, which, if the lamp is brought sufficiently near the magnet, is sufficiently intense to break the filament. The number and position of the nodes formed in the vibrating filament are found to be independent of the natural period of the filament, but depend on the frequency of the alternating current.

STEAM EXPLOSION IN A NEW YORK STATION.

By the explosion of a steam chest in the engine room of the East River Electric Light Company, No. 425 East Twenty-fourth street, this city, last week, Edward Whipple, an oiler, was killed, another oiler was slightly injured, and damage amounting to about $5,000 was caused.

RELATIVE EFFECTS UPON EACH OTHER OF THE ELECTRIC SPARK AND THE FLUORESCENT SCREEN.

BY EDWARD P. THOMPSON.

RECENTLY various writers have discussed the question, What is electricity? Each new fact may assist in arriving more closely at a determination of this question. The following experiments may favor those who hold to the two fluid theory:

I produced a spark between the poles of a Wimshurst machine. The spark, as it appears, may be compared to a ray of violet light entering a dark room, or it may be compared to a fine stream of violet liquid. If a violet ray of light is passed through a fluorescent screen it is of a different color after its transit. The same with respect to white light. For example, I passed a violet ray of light through a screen of barium platino cyanide. As is well known, the light is violet on one side before entering, and green on the other side. I performed a similar experiment with the electric spark.

If the electric current consists of a single fluid having a violet color or white tinted with violet, and passing from one pole to another, then, if it is intercepted by a fluorescent screen, it should appear violet before passing through the screen, and green after passing through it. The experiment showed, however, that the spark was green only while passing through the screen, which was about ⅛ of an inch thick, and made of a translucent mixture of varnish and barium platino cyanide, finely pulverized. If the current consists of two fluids, one coming from one pole, and the other from the other pole, and both passing through the screen, we would expect the experiment to exhibit some violet light in the spark on both sides of the screen, while within the material of the screen, both fluids would appear green. Such was the result of the experiment.

I submit the experiment not for the purpose of proving anything absolutely one way or the other, but to publish the fact established by the experiment as food for thought.

Independently of this experiment, I also produced a brush discharge from one pole. I arranged conductors in such a way that the projected sparks or rays from the pole struck upon the surface of a fluorescent screen, located at the end of an opaque tube, which was provided with metal points behind the screen to act as the other pole. The screen became uniformly luminous by the action of the brush discharge passing through it, first puncturing two thicknesses of black paper. No fluorescence was obtained outside of the path of the brush discharge.

It was necessary for the sparks to pass through the black paper before any fluorescence was obtained. A piece of wood cast as much shadow as a piece of iron. If too thick and not wide, the sparks went around the objects. Other experiments were tried, and they, as well as the above, proved apparently that there are no X-rays radiated from, nor in the direction of, the electric spark, produced by a machine of the capacity of the one I employed—4-inch spark.

March 14, 1896.

AN ELECTRIC THEATRE FOR BOSTON.

A theatrical project is on foot in Boston for an electrical theatre, which will be duplicated in London. The originator of the idea is Mr. Oscar W. Rogers, of Chicago. In 1895 he had a long conference with Wilson Barrett and interested him deeply in his projects. Mr. Rogers also interested the late Eugene Field in the scheme.

The peculiarity of the theatres lies in the way in which they are operated. Mr. Rogers has a series of inventions applicable to stage uses. He proposes to operate nearly everything behind the curtain by electricity. The drops, borders, curtains, both green and act, the side scenes, and, in fact, every mechanism which is now operated by the pulling and hauling of stage hands, will be moved by the electrician at the prompt wing. This will be accomplished by a series of small but powerful electric motors, each working on an independent circuit, and all within easy control of the electrician. Then Mr. Rogers proposes to accomplish scenic effects with electricity. Sunset and dawn, the glare of noonday, lightning and tempest, rain effects, moonlight, and, indeed, every possible atmospheric condition. Illumination, both in front and back of the curtain, will be accomplished in an entirely new and novel manner, and some beautiful effects secured. There will also be electric doors, entrances and exits. On the stage the hands will be limited to the property men and a few assistants, necessary to arrange the "props." It is to be hoped he will think it worth while to provide also a few good plays.

MAY NOT THE X-RAYS PROCEED FROM FLUORESCENCE ONLY ?*

BY WILLIAM JAMES MORTON, M. D.

THE source and nature of the Röntgen ray claim continued interest. An experiment I have made and may here record would seem to demonstrate that the Röntgen ray is a property, neither of the cathode nor (as pointed out by Professor Rowland and Professor Elihu Thomson) of the anode, but rather that it proceeds solely and alone from a substance fluorescently excited within a vacuum tube. In this case, either anodic or cathodic streams projected upon a fluorescent substance, such as the glass of the bulb or other substance supported independently within the bulb, acts merely as a special excitant to the fluorescent. Electricity becomes of secondary importance; it is merely a convenient method of setting up a condition which is of importance, namely, fluorescence.

The accompanying sketch, Fig. 1, and reproduction of a shadowgraph, Fig. 2, are offered in support of these remarks:

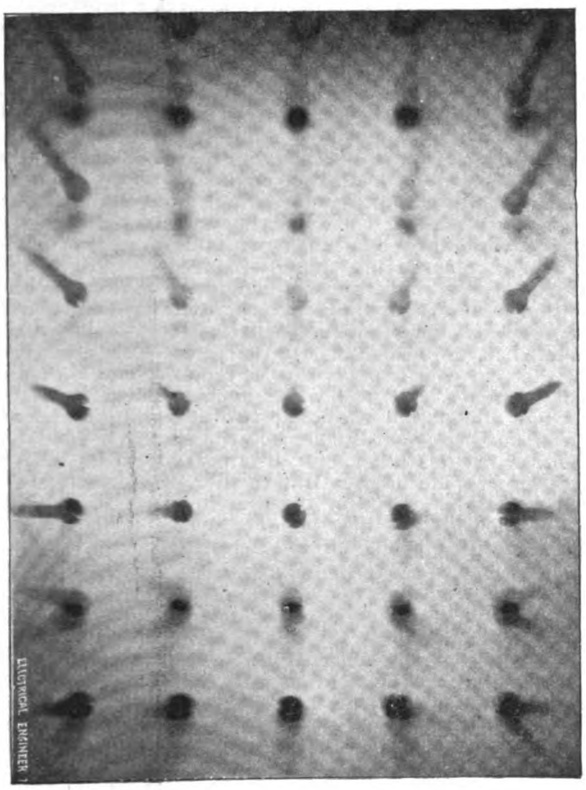

FIG. 2.–PHOTOGRAPH SHOWING LOCATION OF ROENTGEN RAY ORIGIN.

Fig. 1 is a vacuum tube containing a piece of fluorescent substance mounted upon an independent support; c, cathode; a, anode; f, cube of fluorescent material; p, plateholder, containing sensitized plate; r r, radial streaming lines, indicating the source and direction of radiation as shown by the shadows cast of ¼-inch screws placed upon the slide of the plateholder.

The Crookes tube, containing the independently-mounted piece of fluorescent substance is amply defined in the sketch. Upon the plateholder were placed, at the intersections of lines an inch apart crossing each other at right angles, forty ¼-inch screws, resting upon the flat part of their heads. The tube was suspended about two inches above the plateholder and having its longitudinal axis directly above the middle and longest line of screws. The edge of the fluorescing cube was just above the third screw of the middle line mentioned. The plate exposed was 6½ by 8½ inches in dimension and about the length of the tube.

By inspection of the print, Fig. 2, it will be observed that the main effect of the radiation recorded upon the plate was anterior to the cube. The screw beneath the cube has no shadow and may be supposed to represent about the central point from which the radiation emanated. The shadows cast bear out this supposition. There are to be seen other but minor shadows. These were due to a moderate general fluorescence of the tube, to some green streamers which shot out from behind the cathode and to the fluorescence of the glass behind the cube where cathodic rays, which failed to hit it, had passed onward.

The time of exposure was 30 minutes; the excitation (by a static machine) moderate; the action of radiation from the cube was, of course, impeded by passing through the glass at a disadvantageous angle.

I am now using a tube designed to embody this idea of utilizing the radiation of fluorescent material mounted within the bulb and independent of it. The cathodic rays are focused

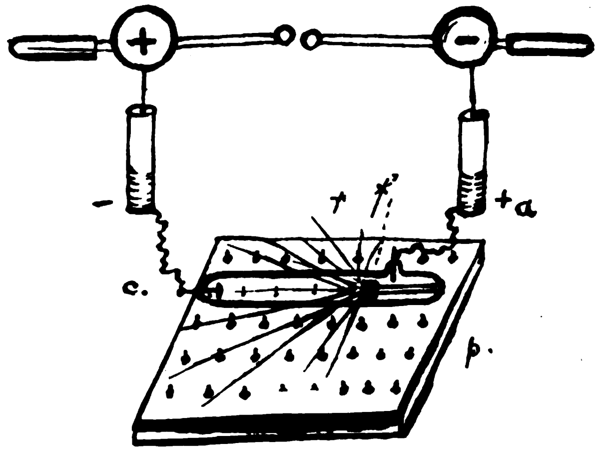

FIG. 1.

upon the fluorescent material, which, in turn, is arranged so as to be the active agency in affecting the sensitized plate.

This experiment tends to show that the X-ray may be due to fluorescence alone. It points to the view that we have merely to deal with a rate of vibration far below that of the familiar infra red rays, but nevertheless, with transversal waves and thus with a phonomenon of the nature of light.

Incidentally, it may be noted from inspection of the print that the shadows cast are opposite to what they would have been had the source of radiation been at the cathode and that they do not correspond with radiation from the anode.

THE DANGERS OF ALTERNATING INCANDESCENTS.

The death of W. S. Goff at Winchester, as a victim of an electrical shock from an ordinary incandescent lamp, brings again before the public the necessity of some legislation whereby the criminal negligence in allowing such conditions to exist should be dealt with severely.

This fatal case is by no means the first, nor will it be the last, of similar deaths from this very same condition, which is well known to electrical men.

It is a case of dollars against lives, and any person who is a user of electric lights supplied from the alternating transformer system, as is commonly done in the suburban districts, places his life in the hands of the electric lighting company.

If the scientific part of the business is looked after by a thorough and competent man not bound down by a niggardly management, the electric lighting in buildings is as harmless to life as a wax candle. But in very many cases, there being no legislation to prevent, an incompetent man looks after the business, caring little for anything but to make the lights burn, draw his salary and trust to luck regarding any one receiving a death-dealing shock.

If a law were passed forcing every electrical company doing commercial and domestic lighting on the alternating transformer system to either regularly test its transformers for leaks between primary and secondary windings and for grounds, or to ground the secondary winding at the transformer, it would eliminate one of the most dangerous conditions known in the electrical business.

I am aware of the objections which may be raised against grounding the secondary winding from transformer, but they are mostly due to the added expense in the construction work.

However, if this were done there would be no more loss of valuable lives through the medium of the innocent-looking incandescent lamp.

If this morning Herald's interview be correct, as it probably is, the superintendent's statement that "there was no indication that any increased voltage was escaping, for the lights did not act in any other than the ordinary manner," it proves nothing but that he is grossly ignorant of the conditions required to cause death, or that he has got a most peculiar kind of electrical construction work existing.—(Boston Herald.)

POWER TRANSMISSION.

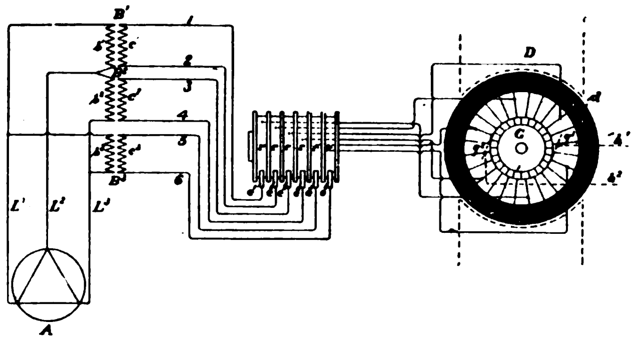
MERSHON'S MULTIPHASE DISTRIBUTION SYSTEM.

IN the transmission of multiphase alternating currents it is customary to employ as few conductors as possible for conveying the currents and to connect these conductors to an equal number of points in the winding of the rotary converter.

Mr. R. D. Mershon, of the Westinghouse Company, has found that by transforming the alternating current thus transmitted into a larger number of phases and correspondingly increasing the number of leads to the rotary current transformer winding the loss in the rotary transformer is decreased; or, in other words, the capacity of a given transformer is increased. For example, if a three-phase current is transmitted over three conductors it may be transformed by means of three converters, the secondary terminals of which, instead of being interconnected, are independently connected with six electrically-equidistant points of the winding of the rotary transformer. The output of the rotary transformer system, so arranged, will be approximately 40 or 45 per cent. greater than if the three main-line conductors were directly connected with three points in the rotary transformer.

The accompanying drawing illustrates in diagram an arrangement of apparatus embodying the above principles.

Referring to the figure, A represents a source of three-phase alternating electric currents, and L' L^2 L^3 three main-line conductors leading therefrom. At the point where it is desired to



THE MERSHON SYSTEM OF MULTIPHASE DISTRIBUTION.

transform the multiphase currents into continuous currents there are placed three transformers B' B^2 B^3 the primaries b' b^2 b^3 of which are connected with the main lines L' L^2 L^3 in the usual manner. The secondary coils c' c^2 c^3 of the transformers are connected with conductors 1, 2, 3, 4, 5, and 6, and these conductors are connected with contact brushes e' e^2 e^3 e^4 e^5 e^6, and through these contact brushes to the single closed armature-winding d of a rotary transformer D. The six contact rings, r, corresponding to the respective contact brushes e' e^2 e^3 e^4 e^5 e^6, are connected with equidistant points in the winding of the rotary transformer. The commutator G of the rotary transformer is supplied with brushes g' g^2, through which continuous currents are delivered to the conductors h' h^2, and the continuous current thus derived may be employed for any desired purpose.

According to Mr. Mershon, the increase of output is due to the fact that at the instant any one of the alternating-current leads coincides with one of the direct-current brushes the current borne by this alternating-current lead is feeding directly into the direct current brush without passing through the armature-winding of the rotary transformer. Consequently the greater the number of alternating-current circuits feeding the armature of the rotary transformer the greater will be the amount of this direct feeding and the less will be the loss in the armature of the rotary transformer due to its being traversed by the alternating currents.

A BROOKLYN POWER WAREHOUSE.

The Brooklyn Wharf Warehouse Company, whose extensive plant extends from Catherine street ferry to Gowanus Bay, has in contemplation the establishment of an electric railroad to facilitate the handling of its merchandise, the abolishment of the present dummy hoisting engines and the lighting by electricity of all their warehouses and elevators. The present plan for the electric road includes a line only from Fulton street to Atlantic avenue.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS ?—V.

BY

Wm Baxter Jr

UP to this point the various directions in which the operating expenses can be reduced are those that relate to a reduction of the coal bill. This item, as has been shown, amounts to about 10 per cent. of all the other expenses, and the portion of it that can be saved by reason of the reduced cost of delivering energy on the track by the electric system amounts to about 55 per cent. But this saving, as has been shown, may be increased in some cases, owing to the fact that the coal consumption of a locomotive is largely dependent upon the skill with which it is handled, while such a condition does not in any way affect the efficiency of an electric motor. It has also been shown that a further reduction can be made, owing to the fact that the weight of electric motors required to haul a given load would be much less than that of steam locomotives of equal capacity, and finally it has been shown that a very decided saving can be made in that portion of the work that is performed by switching engines.

The saving in relation to the coal bill, then, stands about as follows: Total saving equals saving due to reduced cost of energy delivered on track, plus saving due to skill of engineer and fireman, plus saving due to reduced weight of motive power required to haul the train, plus the saving effected in doing the work of switching engines. It is evident, therefore, that 55 per cent. does not represent the total saving that can be effected in the coal bill. Of the three other directions in which the coal consumption can be reduced, one is of an uncertain character, and its bearing upon the final result is not easily determined; but the other two are positive sources of gain and must necessarily increase the saving beyond the 55 per cent. mark; to what extent, it is possible to estimate with a fair degree of accuracy. But further consideration of this subject will be deferred for the present, as it is desirable to point out the various other items of operating expenses that can be reduced by the adoption of electricity.

Reduction of Labor Account.—The work that has to be performed upon a locomotive while in motion is such that the services of two men are required, one to control the movements of the engine, obey the signals along the track, etc., and the other to attend the boiler. With an electric motor, as there is no boiler or its equivalent to take care of, the services of the fireman become unnecessary. It is claimed that, although this is true, nevertheless an extra man would be required to take the place of the motorman should he become disabled through any cause. This is undoubtedly true, for it is easily conceivable that the motorman might, without warning, be seized by a fit or a fainting spell, or drop dead from heart failure, and in such an event if there were no one to take his place the results might be very serious. It is further claimed that in passenger service the presence of a second man is required so that the risk of misinterpreting the signals along the track may be reduced to a minimum, the explanation of this being that the fireman tells the engineer what his interpretation of the signals is, and if the engineer is of the same opinion the train goes ahead, otherwise it is stopped, and the real situation ascertained.

A train drawn by electric motors would require the presence of a second man, while in motion, at the side of the motorman, but, as will be shown further on, this man could have other duties to perform, and his wages could in no way be charged up against the cost of operating the motors. The use of two men so as to avoid misunderstanding signals would hold good on an electrically operated road if the present block signal system were used, but it is perfectly feasible to control the movements of trains on a road operated by electricity, by an automatic system, in which the judgment or watchfulness of the motorman would not have to be depended upon. In such a system every train would be under the control of the train ahead of it, and would be automatically stopped as soon as the distance between the two became less than that to which the system was adjusted.

The motion of trains would also be governed by the position of switches along the track, or by a train coming in the opposite direction. Such a system would be far more reliable than that now in use, which depends not only upon the watchful-

ness and intelligence of the engineer and fireman, but also upon the reliability of the operator who controls the signals. That the present system is not absolutely safe, is well demonstrated by the many accidents on record that are chargeable to it. It would, therefore, be folly to use the present system when a new one could be adopted that would not only be safer, but more economical, not only because it would reduce the cost of operating a train, by so simplifying the work of the motorman as to make it unnecessary to employ two men specially for this work, but also because a large portion of the wages of men required to operate the present system would be saved.

It is claimed by many who profess to be experts in railroading, that the reason why locomotives do not make greater mileage is not so much because they will not stand the strain, as it is, that the duties of the engineer and fireman are so great and their nerves are so taxed by the constant watching of signals, that they could not endure the strain for any greater distance. If this is really so, then the automatic block system that could be used on an electric road would enable a motorman to cover a much greater distance per day than the present run of a locomotive, because the greater part of the work of watching for signals would be done away with.

As to the ability of motors to withstand the strain, we know that they can run eighteen hours per day without any undue wear, as thousands of them are doing that much work every day at the present time, and in the most trying kind of railroad service.

It is evident that if the above assumptions are correct, the system of automatically controlling trains, as suggested in the foregoing, would make a great reduction in the labor account, as the daily runs would be of longer duration and therefore cover more miles; hence the labor account per train mile would be greatly reduced.

There is one item in the expenses of operating steam roads that would be entirely eliminated by the adoption of electricity, and that is, the cost of supplying fuel and water along the line for the locomotives. In a great many places water has to be pumped into the tanks from which the tenders are replenished; coal also has to be elevated into pockets, considerably higher than the top of the locomotive tenders. These coal and water stations require attendance, and the amount spent per year in this direction runs up into large figures. The latest railroad reports do not give the operating expenses sufficiently in detail to enable one to determine what percentage this item forms of the whole, but an old report of the New York Central Railroad gives the amount expended for this purpose as equal to about 10 per cent. of the wages of engineers and firemen combined, or, in actual figures, $110,430. The total expenses of operating the road for that year footed up about $18,000,000, so that the cost of coal and water station attendance constituted about six-tenths of 1 per cent. of the whole cost of operating the road.

THE NEW NIAGARA TROLLEY BRIDGE.

The bridge soon to be built across the Niagara gorge by the Niagara Falls and Clifton Suspension Bridge Company, will be a remarkable one in several ways. It will have a span, between centers of end pins, of 840 feet, and will be much the longest arch span in the world, the present longest span being the 566 feet of a bridge at Oporto, Portugal. The arch will be built out from either end, without false works, which would be quite impossible in the Niagara gorge. The bridge will carry one floor forty-six feet wide, divided longitudinally into three parts. On the middle portion will run two trolley-car tracks; this is twenty-two feet nine inches wide. Each side of these tracks will be an eight-foot roadway for carriages, and outside of these will be raised sidewalks three feet nine inches wide. The suspension bridge now used for highway and footpath will be kept in service until the new arch is ready for use. The center lines of the two bridges do not coincide, being on the New York end about thirteen feet nine inches apart and meeting on the Canadian side.

ADVERTISING IN TROLLEY CARS.

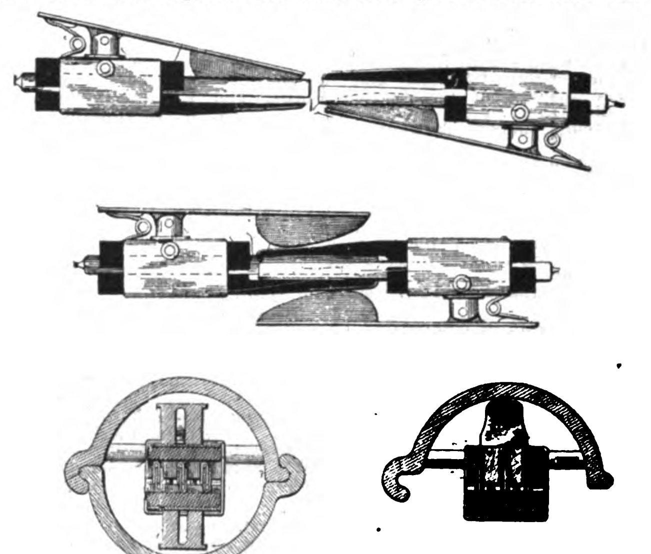
A street railroad company in Pennsylvania, which sought to recover on a contract for advertising in its cars, failed in court for the reason that advertising was not its legitimate business. The courts are again asked to pass on this interesting question. A stockholder in a Pittsburg street railroad corporation is suing for an injunction to restrain the corporation from engaging in the advertising business. The corporation, the petitioner says, was created for the sole purpose of constructing and operating a street railroad, and for the conveyance of passengers and produce only on its railway. It has no right or power to engage in any other business, and its wrongful entry into the advertising business puts in peril the charter and franchise of the corporation and the interests of the stockholders.

DEVINE'S AUTOMATIC ELECTRIC TRAIN SIGNAL.

When Mr. Westinghouse applied his air whistle to railway trains, there were railroaders who believed that the millennium had been reached as far as signaling was concerned. A clever contrivance is this air signal, but it is still restricted to passenger trains, and may be for many years to come. The other half of the railway world—freight service—is still left to the tender mercies of the "bell cord."

One does not need to have more than a superficial knowledge of railroading to know that the present system of signalling on freight trains is very defective. There are no means of rapid communication between front and rear trainmen. The bell cord is a useless ornament; in nine cases out of ten it is not in working order when required and owing to this lack of means of rapidly calling for brakes, loss of life and property frequently result. It is with a view of filling this serious want that the Devine electric train signal was invented. This signal system consists of three small insulated wires running from end to end of the train through a weather-proof cable. At each end of the cable is a coupling, as shown in Fig. 1, which is coupled onto a similar one at the locomotive and caboose.

When the couplings are closed, as shown in Fig. 2, there is direct and instantaneous communication between engineer and rear trainmen by means of push buttons and bells in locomotive and caboose. Two open circuit batteries are used at each end. A code of signals has been arranged to establish communication between front and rear trainmen on moving freight trains.



FIGS. 1, 2 AND 3.—DEVINE'S AUTOMATIC ELECTRIC TRAIN SIGNAL.

By means of this code rapid communication is effected. But provision for rapid communication between engineer and conductor is the least of the merits of the invention. Another, that will be appreciated by railway companies is, that danger of collision between sections of broken freight trains, may be avoided by the use of the new signal. Up to the present, the breaking of a simple coupling link has always been attended with great danger, all the greater if the break occurs on a grade or on roads where the block system is not in vogue. The Devine signal gives alarm at both ends as soon as a train parts and this it does automatically. Interlocking metallic plates, B B, inserted in the coupling tubes, as shown in Figs. 1 and 2, cause the wires to short circuit automatically at the point of separation. The bells start ringing immediately in the caboose and engine cab, warning the trainmen to reverse the lever and apply the brakes.

The device is very simple and cheap. Messrs. Otto & Noad, of this city, are making arrangements with some of the leading roads to have practical tests made.

FORBIDDING TROLLEY FREIGHT IN NEW JERSEY.

In the New Jersey Legislature on March 11, the House, after a long discussion, and by a vote of 43 to 8, passed the Skinner bill prohibiting trolley companies from carrying freight.

CONTENTS.

THINGS THAT ARE FREE.

At such a time as the present, when two of the largest electrical manufacturing companies in the field of electric light and power have decided to work together instead of against each other, it is of interest to inquire how much of the art or industry they can control by the combination of their patents. It might seem that this patent pooling would operate seriously as a bar to general freedom of trade, but we are free to confess that few real features in the nature of patent monopoly arrest our attention, although a great deal is said about them in the recent proclamation. The wonder is, not that so much has been tied up, but that so much is left free and is absolutely uncontrollable, except, of course, by a policy of low prices.

As a matter of fact, the manufacture of all direct current dynamos and motors is to-day broadly free. There are, no doubt, many excellent detail and specific patents worth having, but they are in various hands, and are often conflicting by their very nature. In other words, any man to-day who is a competent designer and builder, can turn out a direct current dynamo or motor of the best form and the highest efficiency, and pay tribute to nobody. This is true of practically all sizes.

Not less is it true of alternating current apparatus of the generating class. We know of nothing that can restrain any one from manufacturing good alternating generators. Such machines are really the oldest known to the art, and, while here again, definite types are patented, the main idea has long been public property. Even the two-phase generator is broadly free. There are very broad patents on two-phase motors and schemes of distribution; but, even here there has been no adjudication in the patents; and the whole attitude of the courts is unfavorable to the sweeping interpretations that were in vogue ten or fifteen years ago.

Next come the lamps. Anybody to-day can build a good arc lamp and a good incandescent lamp in absolute security. There are many excellent patented types on the market, in both classes, but their mutually conflicting merits are not only a justification of their existence, but a guarantee of that competition which is the best condition of things for any art.

The field of work next in line is that of the electric railway. So far as we can see there is here nothing controlling, except the under-running trolley patent, in its limited and restricted form, with the auxiliary switches. It would be remarkable if no other method should be found feasible but that. As to the underground trolley, there must be a dozen practical systems now available. Besides, even if the underrunning trolley be more of a "club" than is believed, the temper of the great street railway corporations is not such that they would readily tolerate its application to themselves when they are in the market for generators, motors or general supplies.

The three-wire system of distribution also has, we take it, a patent life of two or three years here; but it is a fact that the Hopkinson patent has expired in England and is now seeking revival. But if that were used offensively, is it likely that the results would be any happier than they were in the lamp fighting?

And this brings up, incidentally, the position of the licensee local companies, particularly the Edison. This new "deal" must certainly exclude the Westinghouse Company from all of their territories, which are some of the richest in the country, and should, one would think, render helpless and hopeless the Westinghouse stations that now exist in Edison districts. If not, then some compensation must be paid the Edison companies as a matter of equity.

We have not alluded yet to large groups of apparatus and appliances needed in modern light and power work, such as storage batteries, electric heaters, switches, sockets, instruments, etc. In some of these cases there has been extensive and justifiable consolidation, but we should be sorry to affirm that in any instance final and absolute control has been established or can be. Turning to wires and cables, these are all free, subject only to specific patents of limited scope, and the same remark would appear to be true of methods of conduiting and the multitude of devices employed. Then come such varied specialties as converters, electric elevators and carbons. Nobody will be bold enough to assert that these can be monopolized on a patent basis.

If asked to say briefly wherein the combination recently effected and likely, perhaps, to be carried further in a complete union of the two companies amounts to anything, we should be driven to the conclusion that it must rest, not on any patent control, but on a supremacy of merit and quality in manufacturing. Both companies have superb manufacturing facilities, but they are not alone in this respect. There is not likely to be any further trial of the suicidal cutting of prices, from which no one has derived any benefit, not even the public. With their enormous capitalization the two companies must

get decent prices to pay dividends with; and so long as they do that, the electrical trade will have no right to complain. If they do not seek remunerative prices, their early and utter ruin cannot be avoided. As it is, the General Electric Co. must be reorganized, and, perhaps, all the common stock wiped out before its business can be in any shape that a conservative man of affairs not gambling in Wall street would approve of.

GERMAN CENTRAL STATION STATISTICS.

THE statistical tables of the electric light and power industry in the United States have long since ceased to possess that reliability and comprehensiveness which such compilations must have in order to fulfill their object, and even so representative a body as the National Electric Light Association has failed signally in its efforts to place before those interested in the art a reliable record of its magnitude and condition. The chief reason for this unfortunate state of affairs is to be found in the very magnitude of the industry, which now aggregates over 3,000 electric light, railway, and power-distributing stations. The gathering of complete statistics of all these installations would involve a labor and expense of no mean proportions and we hope that future national, as well as State, censuses will eventually put us in possession of the information for all the States, similar to that of New York State, prepared under the direction of Mr. H. A. Foster.

The as yet comparatively small number of central stations in operation abroad has made it possible still to handle their statistics with ease; and among these the German statistics have always been among the most comprehensive and instructive. Our excellent contemporary, the "Elektrotechnische Zeitschrift," in its last issue to hand presents the statistics of German central lighting stations up to Oct. 1, 1895. They are among the most interesting that we have seen in recent years, showing, as they do, the relative popularity of the different systems now in vogue, in a country which has proved by no means conservative in electrical work. The number of stations in operation in Germany at the time mentioned above was 180, as against 148 at the same period a year previous, while it is safe to assume that at the present moment 200 central stations are in actual operation.

The advocates of the continuous-current method of distribution will take much comfort in the fact that that system still remains the favorite in Germany, 80 per cent. of the stations and 74 per cent. of the total capacity being credited to the continuous current. This is indeed remarkable, considering the fact that the polyphase current found its staunchest advocates and first extended application in Germany, over five years ago, a long cycle in the electrical arts. But may we not find a reason for the continuous current's popularity in the fact that of the continuous current stations, no less than 73 per cent. were equipped with accumulators of a total capacity equivalent to 30 per cent. of the engine power? This seems to us more than a mere coincidence, and bears us out in the contention that there are but few situations in which a storage battery could not with benefit be added to the operation of the plant.

Turning to the alternating system, we find that the plain single-phase current has just about held its own, while the polyphase current stations have taken a remarkable jump, so that they now nearly equal in number those operating with single phase, whereas in kilowatt capacity they actually exceed the latter considerably.

The following tabular arrangement brings out more graphically the relative positions of the systems:

	1894.	1895.
Continuous Current.		
Number of stations	120	139
Capacity of stations ....in K. W.	468	35,166
Alternating Current.		
Number of stations	15	16
Capacity of stations ....in K. W.	4,208	4,396
Polyphase Current.		
Number of stations	8	12
Capacity of stations ....in K. W.	2,858	4,468
Polyphase and Continuous Current.		
Number of stations	2	4
Capacity of stations ....in K. W.	646	1,746
Alternating and Continuous Current.		
Number of stations	3	2
Capacity of stations ....in K. W.	175	115

In considering the statistics above it must be borne in mind that more than one-half of the stations have a capacity of less than 100 kilowatts, which indicates the extraordinary economy of operation required in order to make such small stations profitable, and, we think, again gives unmistakable proof of the influence of the storage battery in small central station work particularly.

The 50-watt lamps connected during one year increased from 493,000 to 603,000, or about 22 per cent., while the 10-ampere arc lamps rose from 12,357 to 15,396, or about 24½ per cent., indicating in the latter case a particularly healthy growth, similar to that observable in the United States. But perhaps more marked and significant of all the changes is the increase in horse-power of electric motors connected to the circuits during the statistical year, the capacity of which rose from 5,635 to 10,254, that is, 82 per cent. Though part of this increase is to be credited to electric railway work, the figures nevertheless show an unmistakable appreciation of electric motive power on the part of the Germans.

As regards the character of the motive power employed in German central stations, steam occupies first place, claiming 55 per cent. of the number and 82 per cent. of the power capacity of all the stations. Water power is used exclusively in 23 per cent. of the stations; but these are mostly small stations of less than 100-kilowatt capacity, the combined capacity of which does not aggregate 10 per cent. of the total of all stations. Notwithstanding the popularity of the gas engine in Germany, we find only five stations operated by that method, with a combined capacity of a paltry 265 kilowatt. The advocates of the gas engine for electric lighting must evidently look elsewhere for their shining examples. A glance at the complete tables which occupy six pages of our contemporary makes one sigh for similarly complete tables of our own country. The National Electric Lght Association could in no better way increase its influence than by establishing a permanent statistical bureau, which, once begun, could be kept up with slight effort and expense, and we trust that the matter will receive adequate attention at the convention to be held in May.

ELECTRICAL RULES.

IT is impossible that great good should not result from the insurance and electrical conference held last week, when representatives of all the important national bodies in any way concerned in the promulgation of proper rules for electrical construction and operation, met to discuss and render uniform the rules now existing to govern such practice. The conference was a great success, not only in the character of its members, but in the nature of its deliberations and the importance of the steps taken towards unification. The work that was done was of infinitely greater significance than any mere commercial dicker, no matter how much the columns of the daily press may be loaded with news of the latter. The organizers of the conference deserve much praise and thanks.

The various points taken up by the conference are given in our report elsewhere in this issue. In view of the fact that unanimity and the concurrent action of so many national bodies will give tremendous and decisive weight to the "universal" rules, it is well that no executive powers, for immediate use, were vested in the conference. Such matters as the proper carrying capacity of wires, the grounding of converters and the use of plain iron pipe are not to be disposed of in a casual way. While desiring freedom and cheapness for electrical wiring, we confess our fear of plain iron pipe. If plain pipe, why not bare wire in an insulated pipe? As to grounding converters, that is a ticklish thing. Even now, underwriters protest against the grounding of the neutral in a three-wire system as obnoxious. Then, again, is it not better to go slowly in allowing wires to be loaded, because in England, where different building construction is employed, the heating permissible is higher than here, where everything is so much dryer and hotter to begin with?

The main thing to consider is safety, and the next thing after that is safety; while, if there is any other element to look out for, it is safety. People do not want electric light or electric power or electric heat or electric ventilation or electric cooking or electric elevators, unless each new service is first, and above all, safe.

DEVELOPING DOMESTIC TELEPHONY.

ONE of the recent interesting developments of telephony has been the introduction of the telephone by one local company into the kitchen. For 50 cents a month, the householder can put a one-way telephone into his kitchen, and thus call up the grocer, butcher, coal dealer, florist, plumber or any other retail merchant on the telephone service and give orders. This is a great convenience, and at the rate of less than two cents a day is ridiculously cheap. Besides, it has the advantage of acting as an educator, so that after a short time the user will not wish to limit his conversational resources, but will want to talk to and be in touch with the whole neighborhood. It will be remembered that not long ago one of the New England companies adopted a plan of special temporary service for houses where sickness required the prompt attendance of the doctor. This, again, is but a step towards permanent connection with the exchange and the upbuilding of steady telephonic patronage.

TELEPHONY AND TELEGRAPHY.

THE ERICSSON SWEDISH TELEPHONE.

THE L. M. Ericsson & Co.'s telephone apparatus was first introduced in Stockholm, Sweden, in 1881. Its superior merits were immediately recognized by the General Telephone Company, and adopted by them upon their public service, and in ten years they had 40,000 of them in use. In 1886 the Ericssons reconstructed the General Exchange at Stockholm, placing therein switchboards for 7,000 subscribers. Since then the capacity has been increased to 20,000 drops. This exchange is now considered by some the finest in the world.

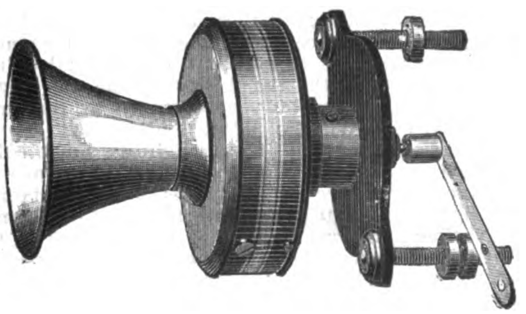

FIG. 1.—ERICSSON TELEPHONE TRANSMITTER.

The Ericsson apparatus is now considered standard throughout Europe, and at a recent test in Japan upon the telegraph line running from Tokio to Kobe, 376 miles, passing through Yokohama, Nagoya, Kyoto, and Osaka, the Ericsson transmitter was found to be the best. The results of the test were very successful, and the government is preparing to open these long-distance lines to the public, using the Ericsson systems. In Germany, Prussia, Norway, and Sweden these telephones are used extensively.

These transmitters have recently been introduced in this country by Williams & Couch, 15 Federal street, Boston, Mass., and used by them upon their improved systems for interior and private line work. They are carrying a large line of the different styles in which they are made, both in the Swedish and American patterns. They import the transmitter direct from Stockholm, Sweden, and are the sole selling agents for the United States.

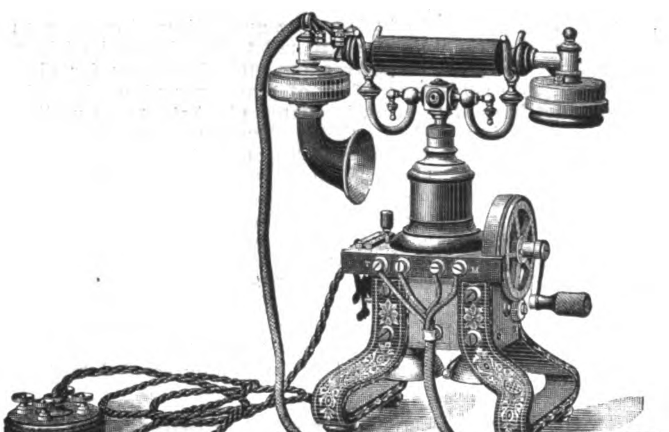

FIG. 2.—ERICSSON DESK TELEPHONE SET.

Fig. 1 shows the transmitter and Fig. 2 a Swedish desk set with hand micro-telephone, while Fig. 3 shows a Swedish wall set.

THE GULF COAST TELEPHONE COMPANY is making rapid progress. Already the line is in operation in Braidentown, Manatee and Orange Ridge, and on its way to Tampa.

INLAND BRAZILIAN CABLE COMMUNICATION.

A telegraph station has been opened at Manaos, Brazil, the capital of the State of Amazonas and the chief emporium of the rubber trade on the Rio Negro, ten miles from its mouth on the Amazon River. Previous attempts to establish telegraphic communication between Manaos and the seaboard by means of land lines have failed. Communication has now been established by means of subfluvial cables in the Amazon. The total length of the river cable is 1,365 miles. The Siemenses have carried out the work.

THE TELEPHONE AT WINDSOR CASTLE.

The Queen has at length decided to put Windsor Castle in direct communication with London by means of telephone. This concession to modern ideas, says the "New York World," is most welcome to the subjects of a sovereign who, even now, prohibits the use of coal, gas and electricity in her private apartments as "new-fangled notions." Some years ago the Prince of Wales strongly urged the Queen to put telephones in all the royal residences, and so seriously did Her Majesty consider the proposition that she sent for the chief representative of a certain telephone company to explain the mysteries of the instrument to her. All went well till the unfortunate agent stated that the person at the other end of the wire responded to a call with:

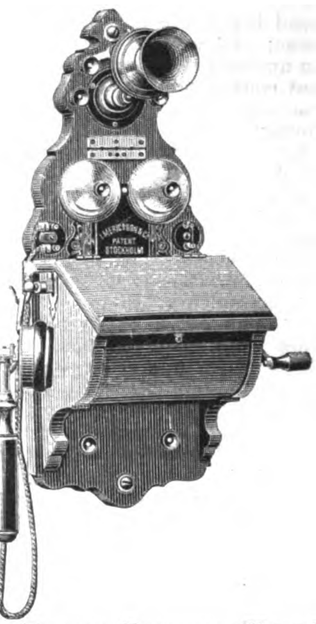

FIG. 3. ERICSSON TELEPHONE WALL SET.

"Hello!"

"What?" interrogated Victoria R. and I.

"Hello, Your Majesty," repeated the blunderer.

The august lady waved her hand to signify that the interview was at an end. She had no further interest in such a vulgar contrivance. That was nearly ten years ago. To-day, however, in view of England's present difficulties, the Queen has waived her objection to the 'phone and permitted the wires to be laid to Windsor. The question of the hour is, What shall be substituted in place of the obnoxious "hello?" "Hail O, Your Majesty," has been suggested.

THE BELL TELEPHONE CO. OF CANADA.

The shareholders of the Bell Telephone Company, of Canada, at a special meeting at Montreal on Feb. 27, authorized the Board of Directors to issue debentures for $600,000 in addition to $600,000 already issued, payable in thirty years, at 5 per cent. The money is wanted to meet various expenses, such as the erection of new buildings, the laying of underground wires in the City of Montreal, and the growth of the business generally, particularly in the matter of long-distance telephoning.

The general meeting of the company was also held. The gross revenue for the year was $1,087,124; expenses, $787,249; net revenue, $299,874. The paid-up capital is $3,168,000. An 8 per cent dividend was ordered paid. The old Board of Directors was re-elected.

EDUCATIONAL.

ELECTRICAL ENGINEERING AT THE UNIVERSITY OF NEBRASKA.

BY T. C. MARTIN.

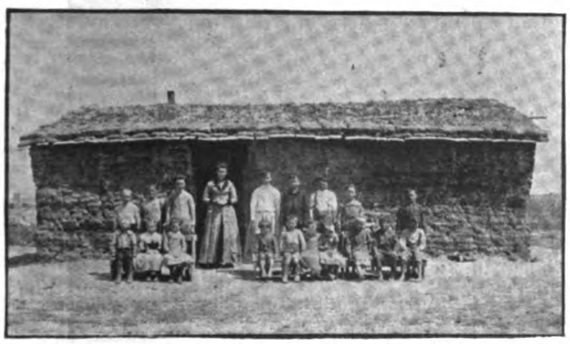
I.

TWO things must strike the observer, in the drift of events at nearly, if not quite, all the seats of learning in this country; and it would also seem that America differs little from more conservative Europe in its educational tendencies. The first of these things is the growing importance of scientific and engineering studies; the second is that electrical engineering is given special prominence and significance in the newer curriculum. With some of us, to whom the time for the study of physics and for laboratory work was grudged, as the recognition of an unworthy ideal, the abundant opportunity now granted freely even for work which requires a student to don a suit of democratic overalls, is looked upon enviously; but there is the grim satisfaction, perhaps, of feeling that after all, while the graduate may be a better engineer than his forefathers had the chance to be, he may have missed something of the sweet and rounding influences of the old "humanities." There are just so many hours in every day, and if they are filled with one study, something else has to go by the board. The net gain, for the present, consists in greater liberty of choice for the student. Later on, probably he and his parents and preceptors will find it well, on the whole, not merely to make an engineer of him, but to turn out, as the foundation for all deeper and specific study, an educated man. This, in turn, implies a longer term of mental discipline, and, best of all, the relegation of higher and special engineering work to a graduate course. Such an evolution is quite easy in places where wealth has accumulated, where education is a heritage of many successive generations, where scholarships and fellowships are abundant, and where the entrance upon professional bread earning is easily postponed; but for many young men and many younger sections of the United States, the problem just hinted at is serious and pressing. What shall a new university do to fulfill the purpose of its existence, and, to be specific, how far can it go in the training of electrical engineers?

PROF. R. B. OWENS.

II.

Here is Nebraska, for example, a State that has been formed and brought into the Union since most of us were born—a State as big as England, with less population than Paris; her people dependent almost wholly on the cultivation of the soil, with no old institutions, no pious founders of colleges, no leisure classes, no millionaires, except those who may yet be. It is readily to be seen that even to provide ordinary education here is no mean task, but when it comes to higher education and then to special training, the outlook would appear hopeless. But they who take pessimistic views do not know the temper of the West. No sooner had these rolling leagues of wind-swept, treeless, black prairie been organized into a State than the university itself reared its first modest buildings; and from that time on the citizens of Nebraska, with a liberal zeal for education that no national endowment of religion ever matched, have taxed themselves through years of prosperity and grinding seasons of adversity alike in order that their children might fight the battle of life on equal terms with the youth of other commonwealths. The bleak winter in which Nebraska set up her standard for higher education by establishing her State University, saw her with barely 100,000 inhabitants. Even to-day she has some 700 sod school houses, humble evidences of a determination that no child shall go untaught, however remote or poor; but she is now laying broad plans for secondary education; and at the upper end of her system is the university, a stately aggregation of modern halls, with 600 alumni, 1,500 students, an income of $163,000 a year; and, best of all, a Chancellor, a Board of Regents, and a faculty, whose ambitions are among the noblest that can stimulate to loyalty and active devotion.



A NEBRASKA SOD SCHOOLHOUSE.

III.

According to figures cited by Chancellor G. E. MacLean, in his profound and inspiring inaugural address before the University, at Lincoln, last February, there were in the State Universities of California, Iowa, Illinois, Kansas, Michigan, Minnesota, Wisconsin, and Nebraska, in 1895, no fewer than 13,500 students, a gain of 320 per cent. over 1885; but during the same period the individual gain of Nebraska was at the rate of 400 per cent., as compared with an average gain in New England colleges of about 20 per cent. This growth would imply not only that the State universities have the hearty confidence of the people, but that successful methods of attracting the right kind of students have been employed. Nebraska has been peculiarly an agricultural State thus far, but she has many other resources to develop, and the growth of population everywhere to-day is so remarkably associated with engineering enterprise that it was early resolved to give a generous portion of her revenues to branches of engineering study. In spite of the difficulties due to a lack of underlying preparatory agencies, from which young men could come familiar with the rudiments of physics, mechanics and mathematics, not less than of languages and literatures, the beginning of the present decade saw the Department of Electrical and Steam Engineering started upon a sound basis. As a matter of fact, this department was an outgrowth from the Department of Physics, and its separate work may be said to have begun in 1891, with an appropriation of $15,000 by the Board of Regents.

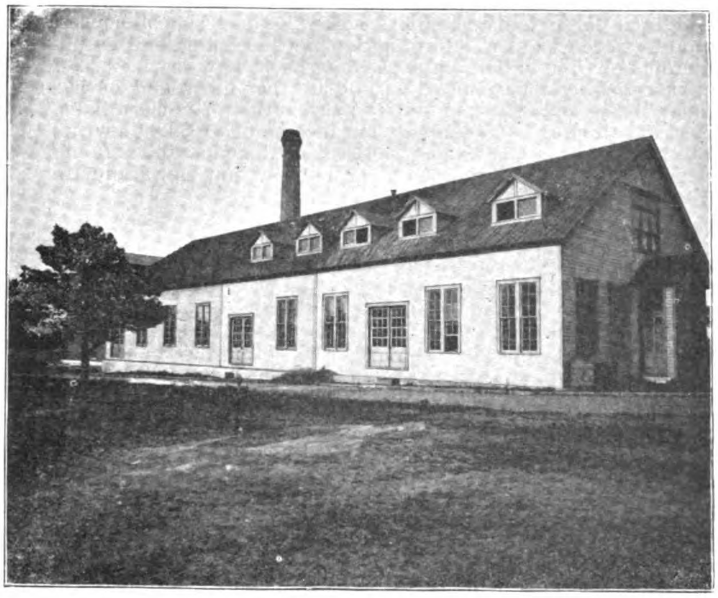
UNIVERSITY OF NEBRASKA. VIEW OF CAMPUS AND MAIN BUILDINGS.

At the present time 92 students are entered for the course in electrical engineering, a number large enough to indicate the popularity of such studies and to provide Nebraska with electrical engineers of home training. The course of study laid down includes thorough work in mathematics, physics and chemistry, applied mechanics, machine design and steam engineering as a basis for the electrical engineering course. Four years, beginning with the freshman year, are required for the Batchelor of Science degree, the last two years of which are devoted especially to electrical work, such as dynamo machinery, electric lighting, electric railways and power transmission, telephone and telegraph apparatus, etc.

From two to three years are required of graduate work for the full Electrical Engineer degree. Throughout the whole work it is attempted to make the student as familiar as possible with the problems he will meet in outside work and to keep him in touch with the latest developments and tendencies.

IV.

The equipment of the Electrical Engineering Department is well illustrated in the accompanying cuts, which show the exterior and interior of the building devoted to its work. The controlling idea has been to make the generating plant fairly represent American engine and dynamo practice, and to have the measuring instruments of such type that reliable commercial tests might be made of all steam and electrical apparatus on hand. Accordingly, it was decided to have both single cylinder, center crank, horizontal and vertical, and compound side crank high-speed engines arranged to exhaust into the atmosphere or to run condensing, and it was also thought best to use shafting as being a method of transmission still in vogue in the majority of American central stations and as affording a ready means of running several dynamos from one engine.



THE ELECTRICAL LABORATORY, UNIVERSITY OF NEBRASKA.

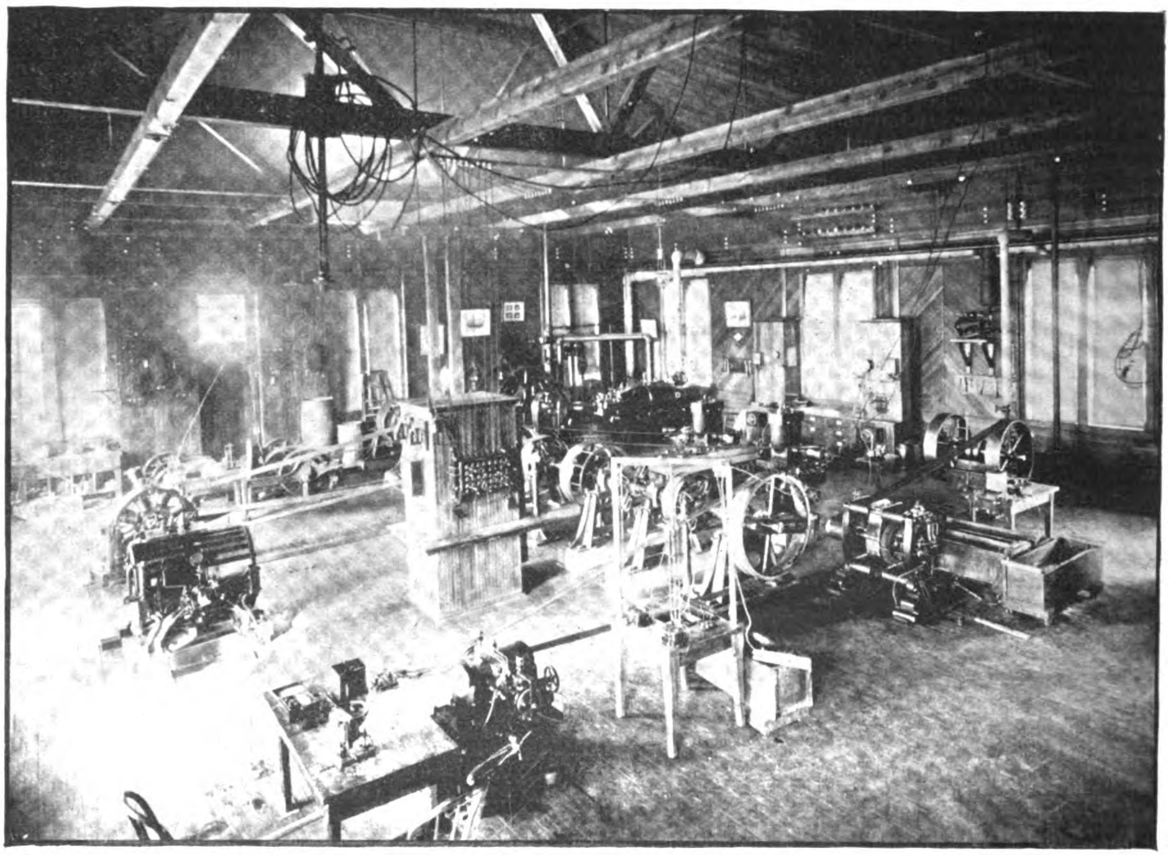
The dynamos include the most important types in general use, namely, low pressure, constant potential dynamos for the two and three wire systems of direct supply; high pressure, alternating current single and multiphase dynamos for long-distance lighting and power; open and closed circuit armature arc dynamos for constant current, together with several inductor machines. To these were added transformers of different makes, alternating and continuous current motors and arc lamps, 500 incandescent lamps, an Otto gas engine of 5 horsepower, together with a storage battery plant of 75 cells of three different makes.

For current measurement by graded instruments, Kelvin balances, Siemens electro-dynamometer and Weston ammeters give a range of from 1 milliampere to 5,000 amperes. For potential measurement by graded instruments, electrometers, Weston and Cardew voltmeters and a Kelvin electrostatic voltmeter give a range of reading from a fraction of a volt to 12,000 volts. Electro-dynamometers, wattmeters by Lord Kelvin, Edelman, Siemens and Weston allow of power measurements from one watt to several hundred thousand. The same range of measurement is provided for in alternating as in continuous currents. Besides the above-mentioned instruments, commercial instruments by the Edison, Thomson-Houston, Fort Wayne and Westinghouse Companies are provided with each system, also the ordinary standard apparatus for magnetic measurements and the measurement of resistance, capacity, inductance, etc., are provided.

For boiler and engine testing, meters, tank and throttling calorimeters, steam, vacuum, and draught gauges, two Tabor steam engine indicators, absorption dynamometers and a transmission spring dynamometer by Van Winkle allow the ordinary tests to be made of boiler and engine efficiency and practice in valve setting, etc.

V.

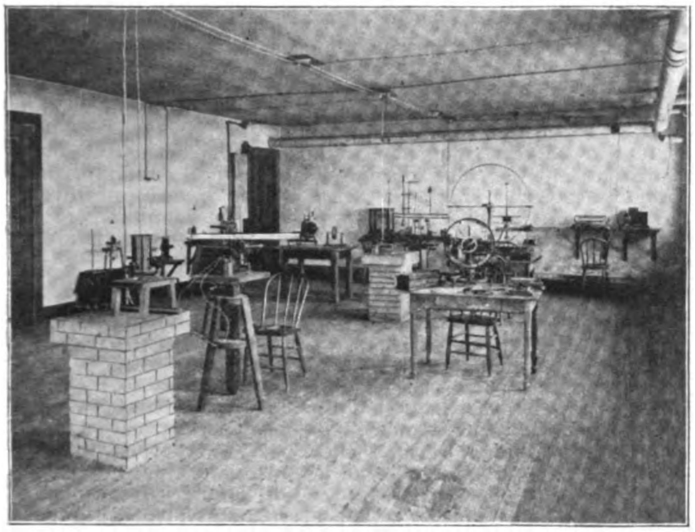
The boiler house is of brick and contains, besides the Stirling boiler for the laboratory, the boilers of the heating plant, feedwater apparatus, coal storage and repair shop. The Stirling



MAIN FLOOR OF THE ELECTRICAL ENGINEERING LABORATORY, UNIVERSITY OF NEBRASKA.

water-tube boiler has a grate area of 27 square feet, a heating surface of 1,150 square feet, and is designed to run continuously at a pressure of 150 pounds and to evaporate nine pounds of water from and at 212 degrees F. into steam at 100 pounds gauge pressure per pound of coal.

The electrical laboratory is built of wood, 50 x 130 feet, with truss roof over machinery, the dynamo room itself being 50 x 60 feet, and the remaining space being reserved for shop work, drawing, and lecture rooms. Sufficient funds not being available at first, it was impossible to build of brick, but a wide foundation was left so that the building might be bricked in and the roof covered with iron or slate at as early a date as possible. The foundations for the engine shafting and dynamos are the best possible, being of hard burned red brick and cement mortar resting on heavy footing courses of concrete. Ample light and ventilation are provided by windows on all sides.



ROOM FOR FINE MAGNETIC MEASUREMENTS.

The shafting in the laboratory is in the center of the building and on the ground, it being thought best not to put it overhead for the double reason of necessitating much more expensive construction of building, as well as being less accessible. The shafting, pulleys, and floor stands were made by the Falls Rivet and Machine Company, of Cuyahoga Falls, O., the shaft being of hammered steel, turned true and polished, 3 15-16 inches in diameter and 33 feet 6 inches long, in three lengths. From it are driven six dynamos, by clutch pulleys, so that any one can be thrown on or off regardless of the rest. The whole shaft can be run from either of the two larger engines or from both together by means of the cut-off couplings. The first driven pulley from the compound engine is bushed with brass and loose on the shaft, but is attached by a dynamometer of the spring transmission type. This dynamometer, by Van Winkle, is keyed to the shaft, and has four springs, giving a wide range of measurement.

VI.

As already noted, there are three engines in this admirable plant. One is a 10 x 18 x 20-inch compound engine, made by the Sioux City Engine Company, Sioux City, Iowa, and designed to run at 125 pounds pressure and 225 revolutions per minute. When indicating 100 horse-power it is guaranteed to show an economy of 25 pounds of steam per indicated horse-power per hour and to regulate within 2 per cent. between no load and full load. The engine has proved very satisfactory in service. The outside fly-wheel of this engine is provided with a two-inch internal flange, so that a continuous stream of water can be kept flowing on its inner side, while an absorption dynamometer is being applied for power measurements.

The second engine is an 8 x 12-inch Atlas and runs at 280 revolutions per minute. Being simple and easily taken apart, it has proved very useful for giving instruction in indicator practice, valve setting, etc. It may be belted directly to single dynamos or to the line shaft with the larger engine The third engine is a small 5 h. p. vertical New York Safety, intended primarily for testing; the throw of its eccentric may be varied, as, also, its angular advance.

To supply water for the condenser there is a large cistern holding about half a million gallons. It is not intended to run the condenser continuously, so that the same condensing water can be used over and over again, time being allowed it to cool down.

On the same side of the shaft with the 3 engines are two 15-k. w. 125-volt Edison dynamos running at 1,500 revolutions per minute. These may be run in parallel, or on the three-wire system; also by a special series winding, any degree of compounding can be had. Both being of the same size and their armature shafts parallel, they may be easily coupled mechanically and electrically and their efficiency obtained under various conditions by Hopkinson's method.

The switchboard for these machines is shown opposite them near the east side of the building. Pulleys of different diameters are provided so that characteristics at different speeds may be obtained and other effects of varying speed studied.

VII.

Coming to the dynamos, the first machine to the left from the large engine is a 1,000-volt 500-light Westinghouse alternator, running at 2,000 revolutions per minute and supplying current to the bank of transformers shown at the north end of the building. This machine is excited by a small United States 110 volt dynamo belted to a pulley on the collector end of the alternator. The switchboard for this machine nearly opposite it contains the ordinary station instruments of the Westinghouse system. A similar switchboard contains the station instruments of the Thomson-Houston alternating system, and the dynamo can be operated through either switchboard at pleasure.

The bank of transformers shown is made up of Westinghouse, National, Slattery, Wagner, Thomson-Houston, and others, from 5 light to 50 light.

The large machine shown on a line with the Westinghouse is a 25 light, 10 ampere Thomson-Houston arc light dynamo, running at 850 revolutions per minute. This machine, together with a 25 light, 10 ampere Wood arc dynamo, driven by the small engine, is connected through lightning arresters and ammeters to a Foster arc switchboard of four circuits, shown between the Thomson-Houston dynamo and the line shaft. Ten ampere single and double carbon, clutch, ratchet, ribbon, and alternating lamps by the Thomson-Houston, Fort Wayne, Excelsior and Westinghouse Companies, are run from either or both the machines and from the alternator. Recently work has been done in the way of changing over the Thomson-Houston machine into a three-phaser, for experimental work.

VIII.

As mentioned before, this laboratory is devoted mainly to engine and dynamo testing and the testing of systems as a whole. The more delicate tests, such as those involving the use of reflecting galvanometers, photometer, work, etc., are done in the Physical Building. The rooms for general electrical testing have piers separate from the building, on which are placed the more sensitive instruments. One room contains the larger number of standard instruments, fixed in position and used for calibrating and the more accurate determinations. The other is devoted more particularly to galvanometer work. Some of the instruments shown in the engravings are Kelvin

LECTURE ROOM, ELECTRICAL ENGINEERING DEPARTMENT.

balances, electrostatic voltmeter, Kelvin quadrant electrometer, Siemens ammeters and wattmeters, large standard tangent galvanometer by the late Troy Electric Manufacturing Company, Obach cosine tangent galvanometer for currents from a fraction of an ampere to several thousand; magnetometer by Edelmann, galvanometer by Queen & Co., earth inductors of Edelmann and Queen & Co., resistance boxes by Elliott and Queen & Co., Cardew and Weston voltmeters, standard cells, standard ohms, etc.

There is an excellent lecture room, besides a private room for the Professor at the head of the department, and every facility is furnished for experiment and demonstration.

IX.

During the recent inaugural exercises at Lincoln, the writer had an opportunity to see the "electricals" at their work and to meet many of them. It was impossible not to be very favorably impressed by such a hearty, sterling, good-natured set of young fellows, so free from "frills," so eager to learn. There seemed to be no trouble in getting work out of them; in fact, a tendency to overdo things was more manifest; and it is a fair inference that a professor in need of stimulus from his charges would here get plenty of it. Many of the men have engaged in special investigations, under guidance, such as efficiency tests on converters, induction motors, etc. One study, that of certain types of arc machines, is to be found in the transactions of the American Institute of Electrical Engineers. Other work in hand the writer would have been glad to secure for the pages of this journal.

To celebrate Dr. MacLean's induction into office, in February, the electrical engineers had organized an exhibition and conversazione of remarkable nature and of brilliant success. The Engineering Laboratory was thrown open to inspection, and the gymnasium was filled with special exhibits, ranging from acetylene and cathodographs to electric cornpoppers and electrolyzed gas pipes. The calcium carbide for the acetylene gas was made beforehand on the premises. Over the campus flew a glittering Franklin's kite, outlined in incandescent lamps, with a flashing tail as long as that of a comet. All this was done with the hearty goodwill of Dr. MacLean, who, though a former professor of literature at the University of Minnesota, shows himself most anxious for the prosperity of the engineering studies.

X.

It is proper, in closing this brief review of the splendid work thus being done by a Western university in higher technical education, to note that the success already reached must in no small measure be attributed to Professor R. B. Owens. No elderly man would have cared to take up the task that he assumed some five years ago of organizing the new department; but even in a country where youth is counted chief among the virtues, it is a little surprising to see the responsibility resting upon the subject of this personal note. Professor Owens might in a sense be taken as typical of the energetic New South, for he was born on a plantation in the southern part of Maryland, a State of which his mother's great grandfather was the first Democratic Governor. He spent three years in an old military school of Maryland, and was the youngest to graduate since its founding in 1774. After a brief connection with the old Baxter Motor Company, he resumed study at Johns Hopkins University, under Dr. Louis Duncan, and stood well in mathematics and physics. He was then for a time with the Excelsior Company in New York, and put in and superintended the Thomson-Houston station at Greenwich, Conn. Study was not neglected, mean time, for in 1891 he received the post-graduate degree of E. E. from Columbia College, in the first class to receive it in America, having been a student under Professor Crocker. When the University of Nebraska wanted to make its new departure, Mr. Owens was invited to go out there, and he was made Adjunct Professor of Electrical Engineering. In 1894 he became full Professor of Electrical Engineering, and in 1895 he assumed full charge of the Department of Electrical and Steam Engineering. He was a member of the International Electrical Congress of 1893, and a Judge of Awards in Electricity at the Columbian Exposition of that year. He is a member of the American Institute of Electrical Engineers and the American Society of Mechanical Engineers. Prof. Owens' forte strikes one as that of organization. He is moreover appreciative of the practical and commercial side of engineering, and while he encourages his students to grasp theory with full realization of its meaning, he aims also to make them take hard-headed views of the problems of engineering, as they are to be found, in actuality, on the prairie floors and broad rivers of the Central West.

XI.

As an example to other manufacturing concerns the writer cannot refrain from adding here a list of apparatus that has lately been loaned or given to the department: Thirty-light arc dynamo and 30-arc lamps, the Excelsior Electric Company, New York, N. Y.; Fleming alternating arc lamp, Fleming-Spence Electric Company, New York, N. Y.; automatic welder and reactive coil, Thomson Electric Welding Company, Lynn, Mass.; two 20-light transformers, Wagner Electric Company, St. Louis, Mo.; 30-light transformer, Lakon Electric Company, Chicago, Ill.; electric welded rail joints, the Johnson Company, Johnstown, Pa.; tested samples of iron and steel, Carnegie, Phipps & Co., Limited, Pittsburg, Pa.; tested samples of steel pipes, Riverside Iron Works, Wheeling, W. Va.; parts of boiler, Harrison Safety Boiler Works, Philadelphia, Pa.; standard pump in section, Knowles Pump Works, New York, N. Y.; sample boards of wires and cables, J. A. Roebling's Sons Company, Trenton; sample boards of wires and cables, Standard Underground Cable Company, Pittsburg, Pa.; sample boards of interior conduit, Interior Conduit and Insulation Company, New York, N. Y.; storage cells and sample elements, Electric Storage Battery Company, Philadelphia, Pa.; heating and cooking apparatus, Western Electric Heating Company, St. Paul; 60-light dimmer, Iron Clad Rheostat Company, Westfield, N. J.; 2½-horse-power, 110-volt electric heater, Automatic Switch Company, Baltimore; boards of standard instruments in parts, Weston Electrical Instrument Company, Newark, N. J.; slide valve model, boiler tube expander, Sioux City Engine Works, Sioux City, Iowa; street car truck and motors complete, Lincoln Electric Railroad, Lincoln.

It will be seen that the catalogue enumerates some very substantial items. There is no place to which material can be given with better judgment than a college or university, where eager young minds can grasp its principles and where the students if they find it meritorious at once become its ardent friends and advocates.

CORRESPONDENCE TECHNICAL SCHOOLS AS PREPARATORY TO RESIDENT TECHNICAL SCHOOLS.

BY E. P. ROBERTS.

THIS article was suggested by a conversation between a technical journalist and a professor of electrical engineering in a technical school, which school is especially well equipped to give an admirable laboratory course, but has to labor under the usual disadvantage of having a large portion of the course, as now given, necessarily devoted to such studies as must precede laboratory practice.

If students had sufficient preliminary education, the special advantages obtainable from a college course could be utilized to a far greater extent, and the student of the four years' course could attain the same plane as is now reached by the student completing his course, and afterwards taking one year post-graduate work in the laboratory. That the standard for admission can be so raised as to make this possible, does not seem practicable at the present time; nevertheless, there are students who have had such preliminary education as to enable them to accomplish the above desired result; they are able to "pass up" their mathematics and other studies, and to devote the time saved to laboratory practice, in some cases obtaining all the advantages of a four years' course in three years, and in other cases obtaining the greater advantages of the five years, above mentioned, in four years.

Of the students who manage to enter college, there are many who have had very insufficient preparation, and who either fail or drag along in a manner which, possibly, is worse than failure. Of the students who enter technical schools, there are very few who have at all an adequate comprehension of the professional life of an engineer, and of the great advantage to be derived from a thorough training in the principles upon which correct engineering practice is based. Because of this, many students consider the studies, more especially those of the first two years, as tasks rather than as advantages to be grasped. They cannot see any practical application to be derived from the knowledge which the instructors endeavor to impart, and, therefore, to a very considerable degree, they will not use their utmost efforts to thoroughly master the same. If, however, before going to college they had become acquainted with the application of the principles of mathematics and physics to the solving of engineering problems, and comprehended, at least to some extent, the great advantage to be derived from a thorough knowledge of the laws of nature, and the mathematical expressions involved in the application of such laws the probabilities are, that they would devote their best energies to obtain all the benefits possible from their college course, and especially would they be able to take full advantage of the laboratory facilities.

Probably each class in a technical school has some members who have worked in machine shops, drafting rooms, or in the field, before going to college. Such men are often not the brightest or the most showy, in the first year or two of their college work; but, because of the energy with which they devoted themselves to their studies, and, also, because at the same time that they are obtaining instruction in theory, they are amalgamating with it practical application, it is found that, either before they have completed their course, or shortly after they have gone into the practice of their profession, they are in advance of their colleagues.

In addition to those able to take a complete college course, there are many who can merely afford time and money sufficient to spend one or two years in college. Such students are

termed "special students," and, as a general thing, their career is not satisfactory, either to themselves or to their instructors. Possibly the principal reason for this is that the special desire of such students is to obtain laboratory practice, and this their preliminary education does not enable them to do. There are now correspondence technical schools which give instruction on technical subjects, and also on the necessary preliminary and allied studies, and in advanced mathematics. The courses in such schools are proving of value, not only to those who cannot go to college, or who desire instruction in a different branch from that which they followed at college, but also in enabling the student preparing for college to obtain such an education as will enable him to realize and take advantage of the college facilities.

A student can obtain the mathematics, physics, mechanical drawing, etc., necessary not only to pass an entrance examination, but also sufficient to carry him a considerable distance into this course; and by devoting the time otherwise spent on such studies when at college, he is enabled to employ his time in laboratory work. He also, if he so desires, obtains a preliminary education in the engineering specialty which he expects to follow, and, as he proceeds with the college studies, he appreciates the advantages which may be derived from them, largely because he can note the practical application. If he takes a special college course, he has had such an education as enables him to spend his time at college to far better advantage than would otherwise be the case.

That correspondence instruction is a success is known to thousands who have obtained either their entire education or a very considerable portion of same by such methods. It is probably unnecessary to state that, in order to obtain the full benefits of such a method, a student must be in earnest, be willing to devote his time to study, and not be satisfied with the mere enrollment of his name in some technical school. It has been abundantly proved that, for those who are in earnest, correspondence instruction has resulted in a thorough education; and in addition to the knowledge of principles and facts obtained, there has also been developed in the student a self-reliance and faculty for the accurate and systematic expression of his knowledge to an extent not surpassed, at least, by any other method.

The correspondence technology school therefore offers to the man desiring to go to college (1) a means of preparation, and (2) a means of so preparing as to enable him to obtain greater value from a college course than if the preparation were for entrance only.

As this article deals only with the subject stated in its title, the advantages of a correspondence technical school to those not having had a technical education, or to those whose education was along a different line from that being followed, or to those who desire to be in touch with specialists in that study in which they themselves are specialists, will not be discussed. The correspondence technical school is of assistance to any one intending to follow or practicing engineering.

SPECIAL LECTURES AT THE STEVENS INSTITUTE OF TECHNOLOGY.

It is the intention of the Board of Trustees of Stevens Institute of Technology to present, from time to time, prominent men who will lecture on various subjects which are of especial interest to the mechanical engineer, but not included in the regular course of study at the Institute. The first of these special lecturers, Mr. Richard N. Dyer, of New York, has just concluded a series of three lectures on "Patent Law."

PERSONAL.

HON. GARDINER C. SIMS contributes to the Providence "Journal" a very interesting summary of the facts in regard to the Nicaragua Canal, and presents several strong arguments in favor of the canal as of benefit to American trade and commerce. Mr. Sims is the antithesis of a Jingo, but believes ardently in the extension of commercial opportunities.

MR. THOMAS F. O'CONNOR, who has been nine years connected with the Standard Underground Cable Company, has just resigned from that company to accept the position of Assistant General Manager of the National Underground Cable Company. Mr. O'Connor has been in the underground cable business from its infancy, has seen it grow to its present proportions, and has aided much in that growth. Outside of his broad experience in the underground cable business, in which he is an acknowledged expert, Mr. O'Connor is well known as an inventor in mechanical as well as electrical branches, and he has also the rare advantage of having taken a three years' law course in the University of the City of New York.

SOCIETY AND CLUB NOTES.

ROENTGEN RAYS.[1]

BY MAX OSTERBERG, E. E., A. M., FELLOW OF COLUMBIA COLLEGE.

THE author introduced the subject by a short, but admirable, résumé of the work and researches of Faraday, Maxwell, Hittorf, Crookes and Hertz, which had led up to the discovery of the "X-ray" by Röntgen. The author then continued:

All these points have been verified years ago, and when Hertz commenced to work with vacuum tubes, he was well aware of these properties. He added a valuable suggestion to the work, which Philip Lenard, now professor at Breslau, but at that time privat-docent at Bonn, carried out in a most conscientious and admirable manner. Hertz found that very thin filaments of gold leaf were transparent to cathode rays, for he succeeded in making glass phosphoresce when separated from the cathode by means of a gold leaf. Lenard then made the next step. He suggested investigating whether phosphorescence could be observed outside of the glass tube, and for that reason he sealed a piece of aluminum to one terminal of a glass cylinder, forming what he called an aluminum window. He actually observed phosphorescence outside of the aluminum window, but he could affect a plate only through a distance of 6 cm. He was positive that he had nothing but cathode rays, for he could deflect them by a magnet, just as he could those inside of the glass tube. If he rarefied the air outside of the aluminum window, he could easily increase the distance through which fluorescent plates could be affected. Lenard made use of this observation to draw the very interesting conclusion that cathode rays are not due to radiant matter or Crookes' fourth state, but that it was a property of the ether, a view which had been held by several German physicists without the support, however, of any experiments.

Lenard did a great deal more and valuable work. He determined, for example, that the absorption of the rays which he observed was proportional to the density through which they were passing; he showed that by compressing hydrogen until it had the same density as oxygen, the absorption of both would be the same; but, here comes one of the most essential points to be considered. He was not aware that he had any other but cathode rays. I actually regret to be forced to make this statement, but in these times when scientists make it their chief aim to achieve privileges of priority, they must also be willing to accept a reproach for work which does not directly help to advance.

Thus we have arrived at the essential point of the lecture: At the question, what is the Röntgen ray? I may be pardoned, I trust, for not using the term X-ray, the word used by Prof. Röntgen in his now celebrated lecture, but he availed himself of this term only to distinguish it from the light rays about which he spoke, and probably also to allude to the undetermined nature of the same. To make an attempt to explain the nature of the Röntgen rays and then to state its manner of manifestation, would be working against the natural law of historical development which I have tried to follow up to the present time. We will therefore take up its characteristics.

In order to present the subject to you in as clear a manner as possible, let us compare the properties of the Röntgen ray, whenever possible, with the cathode and Lenard rays; for then, whenever a new feature is introduced, we can more intelligently appreciate it. Any highly exhausted tube, through which the electrical discharge takes place, may be covered with a piece of black paper or thin cardboard, and it will be observed, in a perfectly dark room, that a fluorescent screen, that is, any surface which has been coated or washed with barium platino cyanide, for example, will light up brilliantly and fluoresce equally well, whether the treated side or the other be turned towards the apparatus. This fluorescence is observable through a distance of two metres. Thus we have a phenomenon here, which shows that phosphorescence can be observed through one piece of glass, that glass, however, being the surface of the Crookes' tube and one or two pieces of cardboard. Lenard only found fluorescence in the direction of the aluminum window; Röntgen observed his effect for a distance of two metres; Lenard only through a distance of 6 cm.

Prof. Röntgen tried to deflect the new rays by means of a magnet, as Lenard deflected the cathode rays, but he found it impossible to do so. This introduces an essentially new property—one of the utmost importance.

An attempt to deflect the cathode rays in the tube, which

[1]Abstract of a lecture delivered before the New York Electrical Society, Thursday, March 19, 1896.

produced the phosphorescence on the surface of the glass, showed that in this case the direction of the Röntgen ray would be changed, but only inasmuch as it went forth in straight lines from the spot in which the cathode rays were concentrated. This led Prof. Röntgen to the conclusion that the new ray was generated on the surface of the glass by the cathode, but shortly afterwards he found that an aluminum cylinder, excited by means of the discharge apparatus, will also excite the Röntgen ray. This would lead one to the conclusion that there are no Röntgen rays inside of a Crookes tube, and Prof. J. J. Thomson, in England, made an experiment to prove the correctness of this assertion, which was generally accepted, not only as extremely ingenious, but also as conclusive. To this, however, I cannot agree. Ingenious as it appears, it has no practical value, for the negative result which it obtains is not by any means a proof of the non-existence of the rays inside of a vacuum.

Prof. Oliver J. Lodge, in a contribution to the London "Electrician," Feb. 7, 1896, wrote: "J. J. Thomson has exposed a protected plate in the very rays themselves inside the vacuum and got no result. It looks as if the streaming particles alone could not achieve it." It appears that Professors Thomson and Lodge, and, in fact, a great many others, are not aware of the fact that a highly sensitized plate ceases to respond to the influence of light when inside of a vacuum. In order to act photographically on a sensitized plate, it takes a certain amount of moisture, extremely little, to be sure, as little only as will be in the atmosphere at any time, even in the driest condition, but more than in as perfect a vacuum as is required to generate the Röntgen rays. Now, if a sensitized plate is not even fogged by light it may well be possible that the Röntgen ray develops no actinic effect.

Various other experiments, the details of which I need not now enumerate, led to the conclusion that the transparency of different substances of the same thickness is mainly conditioned by the density, a result similar to the one found by Lenard with his rays. A very carefully carried out experiment, however, showed that density is not alone in its influence; for glass, aluminum, calcspar and quartz all have about the same density, while their transparency for the Röntgen rays varies widely.

Röntgen rays are found to travel in straight lines; they cannot be reflected nor refracted; thus they cannot be focused like light rays, and hence any picture which is made on a sensitized plate will not be a photograph in the true sense of the word, which means the fixing of a real image, but it will simply be a shadow picture, showing the differences between the more and less transparent substances. Thus it happens that the bones of the human hand can be plainly shown, since flesh is more transparent to Röntgen rays than the bones, but, by over-exposing a plate, you can make the bones disappear, too, and if any solid substances harder or denser is inside of the bone, it will then be easily discovered. Dr. Pupin has demonstrated this very conclusively in a shadow picture, a slide of which I shall show you this evening.

Another discovery recorded by Prof. Röntgen is of great interest, for several investigators, American and European, apparently discovered it independently, but, at any rate, later than Prof. Röntgen. Both these gentlemen might have saved themselves the trouble, however, if they had read more carefully the following lines in Röntgen's lecture:

"If the hand is held between the discharge tube and the screen, the dark shadow of the bones is visible within the slightly dark shadow of the hand." This is a very short but precise statement, and, since the beginning of his paper, Prof. Röntgen spoke of working in a dark room with black cardboard over his tubes, his process is completely defined. If he can thus see bones through the hand on the fluorescent screen, there is no reason why he should not see the movement of joints.

Mr. E. P. Thompson, of this city, has published a very ingenious and interesting device for doing that same thing and called it a kinetoskotoscope, and Prof. E. Salviono, in a communication made to the Medico-Chirurgical Academy of Perugia, on Feb. 6, 1896, has described a similar arrangement, which he called a cryptoscope. Although the respective boxes and arrangements of both these gentlemen may be new, the discovery itself belongs again to no one but Prof. Röntgen.

Now it remains to discuss the various experiments made by others than Prof. Röntgen since the announcement of the discovery, and to investigate in which way different methods have been introduced. I will not pay too much attention to the work reported in the daily papers, which, although it may be correct, lacks the guarantee of exactness which the recognized technical journals give it. In the first place, we must consider the method of generating the Crookes' tube discharges. In his lecture Prof. Röntgen mentions the use of a Ruhmkorff coil; this simple device alone, however, will not, according to various experimenters, produce the best results.

Dr. Pupin has used in connection with his induction coil in the very beginning of his experimental work an oscillatory discharge and a disruptive spark gap; of late, however, he has introduced a new device, which, judging from the good shadow-pictures obtained, works remarkably well. He kindly loaned it to me this evening, thus giving me an opportunity to explain and show it to you. It consists simply of a direct current motor with a make and break commutator. Whenever the circuit is broken the intensity of the current is greater than when the circuit is closed, and since this make and break takes place about sixty times per second, we get very powerful effects at the cathode of the tube. Dr. Pupin found this device preferable to the ordinary make and break device in the induction coil because there is no sparking at higher frequency. The little sparking which would be apt to appear at the commutator is taken up by a condenser in the circuit. Mr. Tesla has also used the oscillatory discharge and the spark gap, which, by the way, is the invention of Prof. Hertz, who communicated it in a paper in "Wiedemann's Annalen" in 1887. The Holtz and Wimshurst machines, which have been considerably used, have also shown their efficiency in this connection.

The next important point is the vacuum tube. A person experimenting with the Röntgen rays should post himself thoroughly on the work done by Hittorf, Pluecker, Elster and Geitel, Spottiswoode, Crookes and others, and he will save himself much trouble, for these men have made as careful a study as possible of the manifold phenomena which present themselves when experimenting with these tubes, and many puzzling questions are discussed and partly solved by them. To mention but one of the most interesting and at the same time most annoying occurrences. When a very perfect tube is used with a vacuum it is found to actually improve, when the discharge takes place for any length of time, that is, the tube will require a greater pressure at its terminals to allow the discharges to take place, and after a while the resistance of the tube becomes so high that no spark can be made to go through. Suppose that you take the same tube and use it with an induction coil with a rather large number of makes and breaks, it may again for a time be used; then it may again be used for a short time on the induction coil with the oscillatory discharge in its circuit. After that, air must be let into the tube and the tube re-exhausted.

This phenomenon was observed some weeks ago independently by Dr. Pupin, Mr. Tesla and Mr. Edison, but, as a matter of fact, it is not new, for Crookes, as well as Spottiswoode, knew of it and mentioned it in the "Philosophical Transactions" many years ago. Mr. Tesla bows submission to a theory of actual mechanical expulsion of material particles through the walls of the tube. Edison, on the other hand, believes that the electrodes which extend into the tube, absorb the remnants of the gases contained in the bulb, thus increasing the actual ohmic resistance between the terminals and at the same time making a higher, that is, more perfect vacuum. For my part, I must say that this explanation appears more plausible, for a few weeks ago I used a tube without any electrodes on the inside, but simply two pieces of tinfoil on the outside, but found no such change, showing that the electrodes apparently play an important part in this phenomenon.

I finally come to the sensitized plate. Very little is to be said in this connection as yet, but there is great room for improvement. It appears that a plate which is very sensitive indeed, that is, an instantaneous plate, for ordinary light is not nearly as sensitive to the Röntgen rays as a landscape plate, which remains exposed to the light for a long time. The reason for this probably lies in the fact that a plate sensitized for violet and ultraviolet rays has not as high phosphorescing qualities as plates sensitized for the opposite, or red part, of the spectrum. Mr. Edison has made some interesting experiments in connection with different plates, and the statement just made is based on his results.

Shortly after Röntgen's announcement, it occurred to many people to investigate whether the Röntgen rays would also be found in sunlight or in the electric arc. I will make no attempt to state who first suggested this idea, for, in the first place, it would be too difficult, in the second place it is useless. The question itself is of great importance, for a definite solution would answer such conundrums, as whether the ray requires a vacuum for its generation, whether the cathode rays must be developed, etc. I have a few slides of pictures, taken by Mr. W. H. Freedman, which clearly demonstrate what I want to explain. His results show, beyond a doubt, that the effect obtained is only due to filtration of light. Thus he found, for example, that glass which casts a heavy shadow to Röntgen rays, casts none whatever in any of these instances; furthermore, he found that when the plateholder used was closed with an aluminum slide, instead of hard

rubber, no shadow picture was obtained. The aluminum slide used was only .01 of an inch thick, and is quite transparent to Röntgen rays. Finally plateholders were placed so that the rays of light struck them at an acute angle. In no case was a shadow picture obtained, showing that reflection took place, and proving the absence of Röntgen rays.

Finally, it remains to say a few words on the theory of the new ray. Prof. Röntgen is of the opinion that we are dealing with longitudinal waves of the ether. Up to the present time we have assumed that ether only allows light rays to travel through, and, since we know that light rays progress by means of transverse waves, we have ascribed to the ether such properties as are required to fulfill the conditions for transverse wave propagation. An incompressible fluid, for example, is a substance which allows only a transverse wave to travel through it. We mean by that a wave whose particles move perpendicular to the line of propagation. If it has now been found that there are also longitudinal waves, it simply means that the ether is not absolutely, but simply nearly so, incompressible, for a compressible substance is capable of transmitting a longitudinal wave, or one in which the particles move in the line of propagation.

To speak in detail on these theories, or on the manifold applications to which the new discovery may be put, is at present quite useless; suffice it to say, that when the years roll by and the discoveries of our times are recorded in the annals of history, one of the characteristic endowments to science will be the epoch-making work of Wilhelm Konrad Röntgen.

The lecture was interspersed with a number of experiments, in which the production of X-rays by the use of Crookes' tubes was fully demonstrated, various forms of tube being used. A number of lantern slides were then exhibited, made from cathodographs taken by Mr. Edison, Dr. Pupin, Dr. W. J. Morton and others. Mr. Edison's showed the permeability of different substances. In one of Dr. Pupin's, a hand was shown, in which 72 small shot and fragments were embedded. One of Dr. Morton's cathodographs was a picture of Sandow's foot, in which splinters of glass had lodged, and for which the great athlete had been under treatment. Mr. Ker threw on the screen a series of pictures he had secured by arc light, illustrating phenomena, to which he makes reference in an article in this issue of "The Electrical Engineer."

The lecture was discussed by President Lieb, Mr. N. W. Perry, Doctors Morton and Pupin, Mr. Ker and the President of the New York Camera Club. The audience filled the Chandler lecture room to overflowing. After the meeting Dr. Pupin exhibited to some friends in his laboratory some recent magnificent cathodographs he had taken, one of which was 18x22 inches, and showed the whole arm and hand, and showed also the curious phenomenon of three separate but blended pictures, evidencing activity at both ends of the working tube and at some other indeterminate point.

MR. N. W. PERRY ON THE UTILIZATION OF CULM.

Mr. N. W. Perry, editor of "Electricity," lectured at the Franklin Institute on March 13, on the utilization of the culm piles which have been accumulating about the anthracite coal mines, and which are now occupying valuable space.

This culm, or the finer portion of it, is almost entirely pure carbon. It is mixed with coal of all sizes, from bird's-eye up to stove size. In this condition it is not an economical fuel, as the finer portion burns first and the larger is wasted with the ashes. It can only be used as a fuel economically at or near the banks, for hauling or handling it increases its cost, delivered, to a point approximating that of a graded coal.

It is estimated that 20 per cent. of all the coal removed from the mines is in the culm banks, which are now veritable mountains. A commission appointed by the Governor of Pennsylvania, comprising some of the best mining experts, reported that these banks contained not less than 315,700,000 tons of coal. In the Scranton district alone there is an annual deposit of culm of 1,400,000 tons, or the equivalent of a stream of energy of over 75,000-horse-power—fully three-fourths of the energy of the great water power tunnel at Niagara Falls.

The speaker described what is known as the Dowson process of converting this fuel into a fuel gas, which, with coal at $4.50 per ton, would cost but 6 cents per thousand cubic feet. The fuel is burned in a furnace with the blast produced by a steam injector. One ton of good anthracite coal will produce 150,000 feet of a fuel value about one-quarter that of 16-c. p. gas. This, he believed, could be produced at the nearer coal fields, and piped to Philadelphia with economy.

The lecturer said energy in this form could be much more cheaply transmitted than the same amount of energy could be transmitted electrically. His comparisons, however, were made with electricity at low pressures, 110 and 220 volts, and 1,000 volts, and at these pressures it was easily shown that at the distance of a mile the gas would be the more economical at pressures not exceeding 4 inches of water pressure. No comparison was made for long distances or with a high voltage (say 30,000 volts) and an alternating current.

The lecture concluded with lantern slides showing the culm banks, and the various kinds of furnaces for producing fuel gas and grates for burning small coal.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 104th meeting of the Institute will be held at 12 West Thirty-first street, New York city, on Wednesday, March 25, 1896, at 8 o'clock P. M. Prof. Wm. L. Puffer, of Boston, will present a paper entitled "A New Method of Studying the Light of Alternating Arc Lamps." It will be accompanied by experiments. A meeting of Western members will be held the same evening, Wednesday, March 25, at 8 P. M., at the Armour Institute, Thirty-third street and Armour avenue, Chicago. At the latter meeting the subject will be "The Röntgen Phenomena, Theory and Experiments." It will be presented by Mr. Charles E. Scribner and Dr. James D. Burry, assisted by Prof. W. M. Stine.

MISCELLANEOUS.

MEETING OF THE NATIONAL CONFERENCE ON STANDARD ELECTRICAL RULES.

AT the invitation of the Committee on Standard Rules of the National Electric Light Association, a conference of the various interested bodies was held March 18 and 19 at the headquarters of the American Society of Mechanical Engineers, No. 12 West Thirty-first street, New York City. The meeting was called to order by Mr. Wm. J. Hammer, chairman of the Committee on Rules of the National Electric Light Association, who stated the object of the meeting, which was to harmonize as far as possible the various interests, and, if possible, to produce a standard set of rules for electrical construction which would be recognized and accepted by all who were engaged in such work. He also announced a list of those representatives and associations who had been invited and were therefore entitled to take part in the present conference.

The following representative members responded to roll call: Professor Francis B. Crocker, American Institute of Electrical Engineers; Frank R. Ford, American Street Railway Association; William H. Merrill, Jr., National Board of Fire Underwriters; A. S. Brown, Western Union Telegraph Company; Francis W. Jones, Postal Telegraph Company; Alfred Stone, American Institute of Architects; Capt. Wm. Brophy, National Association of Fire Engineers; C. J. H. Woodbury, American Bell Telephone Company; Lieut. S. Dana Greene, General Electric Company; Charles F. Scott, Westinghouse Electric and Manufacturing Company; E. A. Fitzgerald, Underwriters' National Electric Association; E. V. French, Factory Mutual Insurance Association; Wm. J. Hammer, chairman, Wm. Brophy, Harrison J. Smith, James I. Ayer, National Electric Light Association Committee on Rules.

Also the following complimentary delegates and advisory experts: A. E. Kennelly, E. E., Philadelphia; Wm. McDevitt, E. E., Philadelphia Fire Board; W. J. Jenks, E. E.; E. H. Johnson, Interior Conduit and Ins. Company; Morris W. Mead, superintendent of the Bureau of Electricity, Pittsburg (afterward admitted as a representative of the National Board of Fire Engineers in place of Capt. Brophy, who was already on a committee of the N. E. L. A.).

The following visitors were also in attendance: C. H. Wilmerding, president of the N. E. L. A; Mr. Holloway, late president of the American Society Mechanical Engineers; Professor Hutton, secretary of the American Society of Mechanical Engineers and others.

Upon motion Wm. J. Hammer was made permanent president of the conference and C. J. H. Woodbury, secretary. Upon invitation of President Hammer, Mr. C. H. Wilmerding then addressed the meeting which he did in a few well-chosen remarks. He hoped that the various interests represented would agree upon a uniform code and further suggested that in order to make their work permanent and keep up with changes which experience or changing methods found necessary, that the organization as assembled should be made permanent. Mr. Wilmerding's remarks were well received. Upon motion a committee was appointed to consider the question of permanent organization, namely, Alfred Stone, Francis B. Crocker, Wm. Brophy, Wm. H. Merrill, S. D. Greene, C. J. H. Woodbury. The following committees were also appointed; By-

Laws, Crocker, Merrill, Brophy; Wiring Rules, Crocker, Ford, Merrill, Stone, Fitzgerald, Brophy, and French.

The committee on permanent organization later reported unanimously in favor of such a plan, and that only national bodies be represented, but that manufacturing or supply companies might be admitted as associate delegates without the right to vote; the organization to also have the right to avail itself of the advice or experience of experts in their various capacities.

The report was adopted and the secretary instructed to extend to other national bodies not now represented an invitation to send representatives to future conferences.

Under this decision future conferences will be composed as follows if the invitations are all accepted:

American Institute of Electrical Engineers, American Street Railway Association, National Board of Fire Underwriters, American Institute of Architects, National Association of Fire Engineers, Underwriters' National Electric Association, Factory Mutual Insurance Association, National Electric Light Association.

Invited—American Society of Civil Engineers, American Society of Mechanical Engineers, American Institute of Mining Engineers, American Society of Naval Architects and Marine Engineers, National Master Builders' Association.

Associate Members—Western Union Telegraph Company, Postal Telegraph Company, American Bell Telephone Company, Westinghouse Company, General Electric Company, and others.

Through the courtesy of the American Society of Mechanical Engineers, the building at No. 12 West Thirty-first street, New York City, was made permanent headquarters, where communications of interest to the committees or conference can be addressed.

CAPT. BROPHY read a paper on the history of attempts at formulating standard rules by the National Board of Underwriters and others. The present attempt to standardize rules is the second attempt of this kind, a similar meeting having been held in Cape May, in May, 1890. That meeting formulated a set of rule that were satisfactory to all interests at the time, but a second meeting of this kind has never been called until the present one.

MR. JENKS spoke in the same strain and expressed the opinion that as far as possible rules should be few and simple and should be rather prohibitive than educational; that they should rather say what should not be done, than to issue a set of instructions to incompetent wiremen; in fact, a set of insurance commandments. The opinion was also expressed that we should avoid the error of the English Board of Trade, which hedged the new industry with so many rules and restrictions that development and improvements were almost impossible and electric lighting became an expensive luxury. We should rather strive to encourage than throttle the young industry.

The conference then took up the subject of rules. In this connection it might be mentioned that six different codes now in use were shown at the meeting, viz.:

National Electric Light Association, National Board of Fire Underwriters, Associated Factory Mutual Insurance, English Board of Trade and Phoenix Rules (new); German Code (new); Edison Illuminating Company.

The first four codes were printed for the use of the conference in one book in parallel columns for comparison. The set of rules issued by the Factory Mutuals is a model instruction book, and was evidently written for the information of factory-owners. Almost every rule is accompanied by explanatory notes as to the reasons for such rule, and in some cases authorities are quoted. The rules follow closely those of the National Board of Underwriters for 1895. The first three codes mentioned are very similar, but that issued by the N. B. F. U. showed more careful study in its construction than the others, and was taken as a standard with which the others were compared.

One point brought out in the discussion was that the rules of the N. B. F. U. were primarily composed with reference to the first risk involved, while those of the N. E. L. A. had in view good construction. While the two objects are similar, they are not always the same. Thus a circuit might be run in such a manner as to be a safe fire risk, but very poor construction from an electrical point of view; while, for example, wires fastened to woodwork may be good electrical construction, yet, for well-known reasons, insurance men could not generally indorse or allow that kind of work.

MR. MEAD spoke of the means of enforcing these rules by legal and political means. In all cases where wiring came under the control of civic authorities the various boards should have this code of rules brought to their attention and adopted. In some cases it will be necessary to use political influence to accomplish this, but as a general thing they would be adopted without question, but penalties should be provided for their violation.

CAPT. BROPHY spoke of the Massachusetts law, which compels all cities to appoint an inspector of wires. They hoped in this way to weed out those who were not legitimately in the business. They undertake work that they are not familiar with at prices which freeze out responsible contractors and skimp the job to save themselves from losing money.

MR. A. E. KENNELLY read a paper on the safe carrying capacity of wires. The table of capacity recommended by the English Board of Trade and recommended by the N. E. L. A. allowed a rise in temperature of 10° to 12° C. The table of capacity of wires in use by the N. B. F. U. allows a rise in temperature of from 25° to 50° F., and questioned whether this is not too near the safe limit.

MR. MERRILL, in speaking for the N. B. F. U., said that many contractors had complained that the limit was much too low, and that by increasing the amount of current that may be carried they could get a class of work they could not get without it. The table had been compiled hastily, but actual tests had shown them that the carrying capacity given was safe. It had been a matter of experiment, not theory, with them, and they were well satisfied with the results.

MR. JONES said that the trouble with making the carrying capacity of wires too high was the trouble of making people stick to the limit originally intended for the wires. In case of an office building, for example, an outlet that was originally intended for five lights will often have extra lights or fan motors plugged in by the building electrician without consulting anybody, with the result that many circuits are loaded up to double their original capacity. Inspectors cannot be expected to see all these things, and for that reason the limit of carrying capacity of wires should be low.

MR. GREENE said that in some experiments made by the General Electric Company a No. 00 wire was loaded up to 240 amperes, which is only 20 amperes higher than that allowed in the table, and that the wire got warm enough to soften the rubber. The opinion was that the present table of the N. B. F. U. is too near the safe limit.

MR. KENNELLY was appointed a committee of one to take this subject under consideration, and report to the committee on rules at some future time.

The question was discussed as to whether bus bars should be large. Many widely divergent opinions were brought out, but there was a general agreement that the distance between bus bars and terminals should correspond to the potential used. Referred to the committee.

The question as to whether the dynamo frame should be insulated or grounded provoked a lively discussion. Mr. Scott thought that in alternating plants, insulating the frame was useless and that the static charge might be a source of danger to the attendant from touching the frame, whereas a grounded frame would be a factor of safety. Also that many dynamos carefully insulated at the base were connected to the engine by wire-woven belts. Captain Brophy agreed with Mr. Scott. Professor Crocker said that the static charge can easily be taken care of by grounding through a very high resistance or a wet string or a vacuum tube which would take care of the static charge, but leave the dynamo insulated. The attendant should always be protected by an insulated flooring or platform so that he could not possibly be grounded while handling the machine.

Next came the question as to what was high and what low potential. Professor Crocker said that, as in some cases, 200-volt lamps were being used and asked whether under this rule a three-wire system carrying 400 volts between outside wires would be excluded and treated as a high potential system. He thought the limit as to low potential circuits could be just as well raised to 425 volts.

MR. MERRILL said that his association would object at the present time.

CAPT. BROPHY said the Western Union and several other companies used high voltage and he found it necessary to distinguish between them and companies using heavy currents.

MR. JONES said that in telegraph work potentials varying from 400 volts down were used, but of course the currents were small.

The question of substituting plain iron pipe for the iron-armored conduit now in use awakened the keenest interest. So far as heard from every one present favored the use of plain iron, if they could be convinced that burrs and fins in the pipe would not strip the insulation.

MR. AYER favored allowing the use of two wires in a plain iron pipe.

MR. STONE wanted to know whether the lesser expense would justify making the change.

CAPT. BROPHY said that with insulated conduit the insulation on the wires was apt to be reduced to the lowest possible limit. He favored plain pipe with insulation on the wires.

MR. FITZGERALD saw no objection to plain iron pipe and

said that brass-armored conduit had not fulfilled all expectations. This view was also expressed by others.

MR. JENKS cited the case of fixtures wired ten or twelve years ago with the inferior wires then in use which had never made any trouble, which would seem to show that trouble was not necessarily caused by contact with the metal.

MR. SMITH stated that his company (the N. Y. Edison Illunating Co.) had had very little trouble with wiring done in the old days. The case was cited of large uptown flats wired with underwriters' wire pulled into zinc tubes, such as bell wiremen sometimes use; and while the plant had been installed twelve years, only two or three outlets had made trouble.

MR. KENNELLY could see no use in taking such pains with pipe inside of a building.

PROFESSOR CROCKER thought plain pipe good enough, and that whenever they demanded a pipe with a smooth interior they would get it as they got underground conductors when they had to have them.

MR. MERRILL, while not rising to oppose plain iron pipe, wanted to remind the members of one thing that came up in discussing fixtures. Because work improperly done had gone along for years without trouble, it was no reason for allowing such work generally. Statistics gathered by his association showed that the weak point in wiring systems was apt to be the fixtures.

The question of fuses and cut-outs was discussed pro and con.

MR. M'DEVITT thought that fusible devices were all wrong, and that fuses are not reliable by 100 or 150 per cent.

CAPT. BROPHY thought the ordinary run of fuse blocks a delusion and a snare. Many cut-out terminals are too close together.

MR. AYER opposed referring this matter to a committee as practical men were trying hard to solve this problem.

MR. M'DEVITT thought the question of circuit-breakers should be considered in this connection.

CAPT. BROPHY thought the ordinary run of fuse blocks were not always to be relied upon.

MR. GREENE said that the fuse had been unjustly condemned because the time element had not been considerd; and he referred to some tests showing that the wire can be depended upon to carry more current than the fuse, and that where the fuse does not melt the wire is in no great danger of overheating. Supposing a fuse would not go for five or ten minutes, the wire would not get dangerously hot in that time.

MR. M'DEVITT remarked that even if the wire itself was not destroyed, the insulation might become charred, which would be equally objectionable.

MR. JONES thought some method should be arranged so that a 20-ampere fuse, for example, could not be inserted in a 10-ampere fuse block, and that blocks should be proportioned to the circuits they are intended to protect. He also raised the question as to whether resonance affected fuses.

MR. KENNELLY said that resonance never gave any trouble.

MR. SCOTT—Reference had been made to fuses in the Niagara circuits. There was a wide difference between those and ordinary work. Fuses on these circuits are made very sensitive and blow very quickly. They have had very little trouble at Niagara. In one or two instances has a fuse blown out. A fuse should be marked at the amount of current it is expected to carry, also the current at which it melts. They sometimes find that fuses get hot and melt from loose binding screws. In one case a fuse which melted quite often was located in a boiler room, where the temperature was very high and a very slight rise in temperature was sufficient to melt it. When they buy fuses marked 3, 5, or 10 amperes it simply means little, because they probably don't use the same length or surround it by the same temperature as that in which the test was made.

The question of switches was next discussed and referred to the committee.

The question as to whether the ends of the cord in drop cord pendants should be dipped in solder, or whether the inside of the socket cover should be lined with insulating material was discussed and referred to committee.

A question was raised by Mr. French as to the advisability of doing away with ceiling rosettes. Referred.

MR. KENNELLY thought that the secondary coils of a transformer should be grounded at its center to prevent personal injury and to cut out that circuit in case of trouble.

MR. JONES thought that grounding the secondary would put an additional strain upon the insulation between the primary and secondary coils, which in case of lightning would destroy the transformer.

MR. AYER opposed referring this matter to a committee, as systems grounding the secondary would cause a great deal of trouble. He spoke of an automatic device of high resistance which he had used in his own house which was connected to the primary and secondary in such a way as to open the former in case of any connection between the two coils.

The English and Phoenix rules on this subject were read and discussed at length and the whole subject was finally referred to a committee.

The subject of car wiring brought Mr. Ford up with the remark that this subject had been slighted and not given the attention it deserved. He also thought that under proper restrictions lights and motors might be taken from trolley lines in places where no other electric power was available.

MR. MERRILL asked what restrictions he would have, and then went on to relate that one set of regulations that he had seen demanded that a circuit-breaker, a fuse cut-out, an automatic breaker, and handswitch also be placed in the circuits; that the building in which the motors or lights were located should be practically isolated and the return wire should be carried back to the power station. Under all these restrictions he thought it would be beter to install an isolated plant and under all the circumstances that it would be better to prohibit such work altogether.

MR. AYER called the attention of the committee to electric car heaters and also said that only flexible conductors should be used in car wiring.

When the conference came to the list of wires recommended by the N. B. F. U. the general opinion seemed to be that it should be stricken out and specifications showing clearly the kind of wire desired substituted.

In reading the rule upon the subject of tests (Rule 46) Mr. Kennelly raised the question as to what these tests were based upon. Thus 10 amperes requires an insulation of 4 megohms, or 40,000,000 ohms per ampere, 200 amperes requires 160,000 ohms, or 32,000,000 ohms per ampere, while a current of 1,600 amperes requires only 11,000 ohms, or 17,600,000 ohms per ampere. Of course switches and connections will make some difference, but should it be so much?

It seems that the Boston rule for underground conductors of 20 megohms per mile for each 100 volts is a good one, as it furnishes a definite standard.

This practically ended the discussion on rules, and after a discussion of the question of the adoption of by-laws at the present meeting, the question was laid over.

The thanks of the conference were extended to the N. E. L. A. for their efforts in behalf of the meeting. Also to Mr. Hammer, the presiding officer. Also to the American Society of Mechanical Engineers, for their courtesy in tendering the use of their building as headquarters for the committee. Conference adjourned to meet June 25-26, or sooner, at the call of the chair.

LEGAL NOTES.

THE COMMON CARRIER QUESTION IN TELEPHONY.—AN ADVERSE DECISION.

An important decision was announced by Judge R. G. Siebecker, of the Wisconsin Circuit Court, at Madison on March 18, in the case of the Dane County Telephone Company against the Western Union Telegraph Company. He notified the attorneys he had decided to deny the writs of mandamus asked by the telephone company to compel the Western Union to admit new telephones to its offices.

The question involved was a new one, with no decision of other courts on the point at issue. Judge Siebecker has not filed his opinion in the case, but has formally notified the attorneys of his decision. There is no doubt that the case will be taken to the Supreme Court for a final decision.

Judge Siebecker's decision, as announced to the attorneys, is as follows: "In this case I have found no decision nor has one been cited to me controlling the matter. Upon the principle as to the duties of common carriers I found no adjudication covering the question here at issue. I have come to the conclusion that the application differs radically from the principles determined in cases cited, wherein one common carrier has been compelled to offer the same rights and privileges to the public that it has by means of its relationship to another common carrier.

"To grant the application the court would have to say that the transmission of telephonic messages and the delivery thereof from the office of the telegraph company over the wires of the telephone company is a public right that can be enforced as such, against telegraph companies by reason of its being a common carrier. I think that this principle cannot be applied, for the reason that the telegraph company may deliver its messages or receive messages upon its own terms and stipulations, as long as they are reasonable. The fact that this telegraph company does so for the telephone system of the Bell Telephone Company is a personal privilege or right they may exercise as they may see fit. For these reasons the application must be denied."

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE THOMSON INCLINED COIL PORTABLE ALTERNATING CURRENT INSTRUMENTS.

IN the matter of portable instruments for alternating current work, the practical electrician has, heretofore, been compelled to choose between the high grade, high-priced instrument and the low-priced and usually unreliable one. Reliable portable instruments at reasonable prices have been lacking, and, as a consequence, the demand for them has become both crying and extensive. Realizing this fact, the General Electric Company has undertaken to meet this demand by placing upon the market a complete line of ammeters, voltmeters and indicating wattmeters.

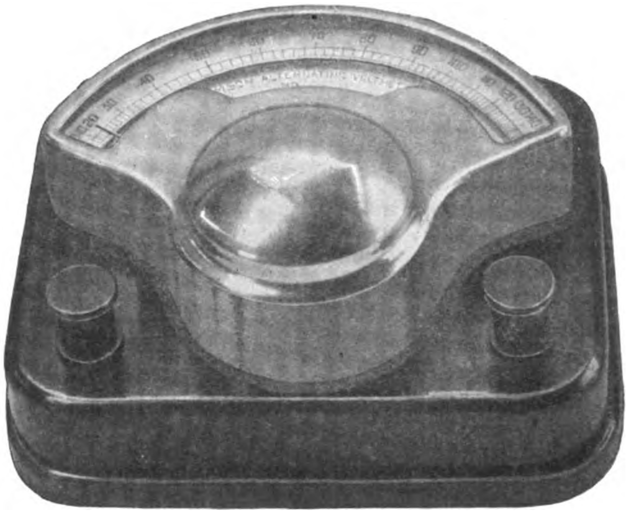


FIG. 1.—THOMSON INCLINED COIL ALTERNATING CURRENT VOLTMETER.

These devices developed by Prof. Elihu Thomson himself embody all the improvements which knowledge of every requirement and long experience suggest. They are compact in form and accurate, and may be used on all alternating current circuits, whatever the frequency and whatever the wave form. No parts liable to change enter into their construction, and accuracy, consequently, is insured for an indefinite period. These instruments are of the series type. The difficulties inherent in shunt instruments are thus absent. They are dead beat, a depressible button operating an attachment by which the needle is immediately brought to rest without detracting from the sensitiveness of the instrument.

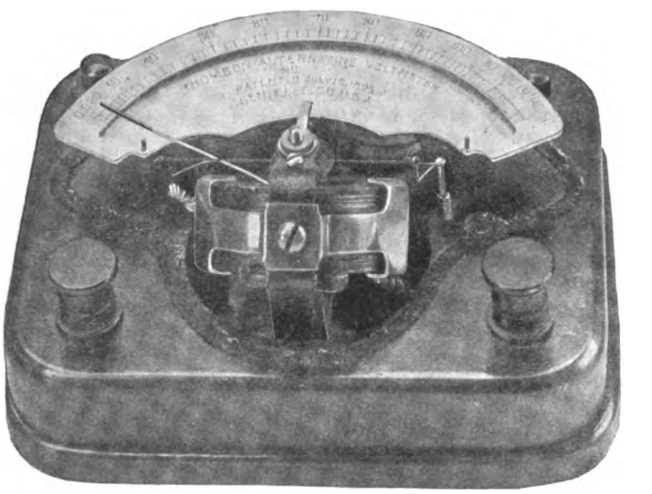

FIG. 2.—THOMSON INCLINED COIL ALTERNATING CURRENT VOLTMETER.

The voltmeters, illustrated in Figs. 1 and 2, are standard for alternating current work, but may be used with good results on direct current circuits in cases where the highest accuracy is not required. The indicating wattmeters give accurate readings with angles of lag on all inductive loads met with in commercial practice. A special field will be found for these in central station practice, testing and calibrating recording meters, testing transformers and measuring their efficiency, in testing the energy consumed in alternating current arc lamps and incandescent lamps, small fan and other motors, etc.

With the indicating wattmeter, shown in Fig. 3, accurate measurements on direct current circuits may also be obtained, provided two observations for each reading are taken with the instrument connections reversed between the readings—the mean of the two readings giving the correct result. Upon each wattmeter the maximum current at which it may be used is marked. They indicate accurately on any potential from 0 to 150 volts.

FIG. 3.—THOMSON INDICATING WATT-METER.

The range of sizes of these instruments is such as to meet all and any requirements. The ammeter is made in the following quantities: 2, 10, 25, 50, 100 and 200 amperes, the voltmeter for 75 and 150 volts, and the indicating wattmeter for 100, 300, 1,500 and 2,500 watts, that for 100 watts having been especially designed for measuring iron losses in transformers and for testing incandescent lamps. The scales are exceptionally long and clear.

In appearance and workmanship the instruments may be favorably compared with the most costly on the market. They are both neat and handsome, having bases of mahogany and covers of polished nickel. Each instrument is packed in a hardwood carrying case. These instruments are known as the Thomson Inclined Coil Portable Alternating Current Instruments, and the principles of construction can be gathered from the illustrations.

THE EDDY ELEC. MFG CO. IN THE WEST.

An important arrangement has just been effected by the Eddy Electric Manufacturing Company, of Windsor, Conn., with Mr. G. W. Russell, Jr., of the Russell Electric Company, of Denver, Colo., by which that gentleman becomes their representative for the district comprising Colorado, Wyoming and Utah. While this region is not thickly settled, it is one where the mining wealth is enormous, and where questions of power transmission assume considerable magnitude. The Eddy generators and motors are already very favorably known in the electric mining field, and Mr. Russell's large experience and acquaintance will prove of great value in his new connection, upon which both parties are to be congratulated.

HOW WOVEN WIRE BRUSHES WEAR.

Mr. W. H. Fleming, 393 Pearl street, New York, has received the following from Mr. D. Howe, electrician for Reed & Barton, the silversmiths, of Taunton, Mass.:

Yours in regard to Woven Wire Dynamo Brushes of the 6th was duly received. On investigation I find that the wear of brushes on three machines in use from one to two years averages about half an inch yearly. As these brushes were five and seven inches long when put on, I shall not need new ones for a long time. With commutator in proper condition, brushes correctly adjusted, the wear is hardly noticeable.

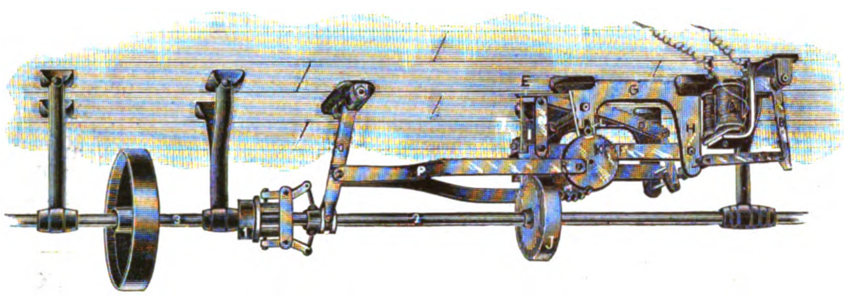
THE STANNARD ELECTRIC CLUTCH.

THE accompanying engraving shows a new electric controller for friction clutches, patented by J. E. Stannard, of 48 Lebanon street, Springfield, Mass. This is designed to controll friction clutches on main lines of shafting, both in stopping and starting, and in case of accident will release the clutch in two to three revolutions, thus preventing serious accidents.

The controller is usually placed overhead, near the clutch, as shown, and takes its power from the driven section of the shaft by means of the friction pulley shown, and is powerful enough to work any size of clutch. In large mills it is designed that each section or floor can be stopped independently of any other, and will only delay the section where it is necessary to stop.

Electric wires are run to all points desired and switches placed where convenient. To stop, it is only necessary to push the switch, which will instantly bring the frictions together and instantly release the clutch from the driving power, and lock it out. As long as the person that worked the switch keeps it out of connection, it is impossible for any other person to start the shaft by any other switch, so that no accident can occur from that source. When ready to start the shaft again, the switch is pushed and the frictions again come in contact, and push the clutch into working position, but at a very much slower speed, so as not to strain or jar the clutch or machinery. This gives full control of shaft for both starting and stopping, and can be placed at any distance, as, for instance, in another building. It will be found a great convenience aside from the safety derived from its use in case of accident, for which it was especially designed.

This controller has been in practical use for the past year and has been found reliable and in one case at least has prevented serious accident. A 50-horse-power clutch occupies a space of 14 x 30 inches over the shaft.



THE STANNARD ELECTRIC CLUTCH.

WATERTOWN ENGINE SALES.

The Watertown Engine Company report the following sales for February:

Clarkson Institute Technology, Potsdam, N. Y., two 50-h. p. vertical direct connected (2d order).

Philadelphia "Evening Telegram," Philadelphia, Pa., two 50-h. p. high speed, direct connected.

Keystone Lime and Stone Company, Tyrone, Pa., one 70-h. p. Excelsior (3d order).

Broadway Central Hotel, New York City, one 70-h. p. high speed, (2d order).

L. Z. Bach, New York City, one 70-h. p. high speed, direct connected.

J. Monroe Taylor Building, New York City, one 50-h. p high speed.

Wissahoming Apartment House, New York City, one 70-h. p. high-speed, direct connected.

Gillespie Apartment House, New York City, one 70-h. p. high speed, direct connected.

Augustus Noll, New York City, one 70-h. p. high speed, (2d order).

New York Electric Equipment Company, New York City, one 100-h. p. high speed.

Wolcott Electric Light Company, Wolcott, N. Y., one 60-h. p. high speed.

C. H. Angus, Albany, N. Y., one 50-h. p. slow speed.

C. R. Remington & Son, Watertown, N. Y., one 50-h. p. Excelsior, (5th order).

J. B. Wise, Watertown, N. Y., one 125-h. p. slow speed.

New Orleans "City Item," New Orleans, La., one 40-h. p. high speed.

Nashua Manufacturing Company, Nashua, N. H., one 75-h. p. slow speed.

Hathorn Fancy Forge Company, Bangor, Me., one 50-h. p. slow speed.

G. R. Andrews, Northfield, Conn., one 75-h. p. Excelsior.

Pacific Lounge and Mattress Company, Tacoma, Wash., one 75-h. p. Excelsior (2d order).

Hydraulic Placer Syndicate, Lewiston, Idaho, one 40-h. p. Excelsior.

Lindell Hotel, St. Louis, Mo., two 75-h. p. Excelsior.

POWERFUL FLUORESCENT SALTS FOR ROENTGEN RAY EXPERIMENTS.

The discovery, which Mr. Edison announces in another column, of a salt which fluoresces far more strongly, under the influence of Röntgen rays than barium platino cyanide, which has heretofore been considered the most efficient salt for the purpose, promises to be of very great importance to all who are investigating the phenomena attending the electric discharge through vacuum tubes.

With this salt properly applied to a suitable screen, the fluorescence is found to be six times as intense as with barium platino cyanide under the same conditions; this, of course, greatly facilitates the work of investigation, and makes it possible to see, at once, results which with the slow and uncertain photographic plate, sometimes require hours to determine.

It is remarkable that, while the effects of the Röntgen rays and their peculiarities have been studied so widely during the past few weeks by means of the photographic plate, so little had been done in simplifying the means for making these investigations. Mr. Edison's very complete tests have made it certain that many substances ordinarily found in the chemist's laboratory exhibit this property of fluorescing under the influence of the X-rays; several substances were found which were more strongly fluorescent than barium platino cyanide, but one of the tungstates of calcium was found to be several times more efficient for this purpose than any of the others.

The theory that it is only the heavier substances which possess this property of fluorescence does not hold good on investigation; one of the light organic salts, salicylate of ammonium, was found to possess it to a remarkable degree. It is found that only a few of the many calcium tungstates fluoresce under the influence of the X-rays; the particular modification which gives the greatest fluorescence without retaining a phosphorescent glow is produced only by skillful chemical manipulation. Mr. Edison is not manufacturing the tungstate himself, but, under his directions, Messrs. Aylsworth & Jackson, of Orange, N. J., have put on the market a "fluoroscope" containing the fluorescent salt prepared ready for use.

AT THE BERLIN IRON BRIDGE WORKS.

The Berlin Iron Bridge Company, of East Berlin, Conn., are very full of work and are running their entire plant with a full force of men. They report contracts lately completed as follows: New casting shop and machine shop for Randolph & Clowes, Waterbury, Conn.; new car house, engine room and boiler house for the Bergen County Traction Company, at Fort Lee, N. J.; a new steel tube plant, including power house, accumulator house, coal storage, etc., for the Pope Manufacturing Company, of Hartford, Conn.; two bridges for the American Sugar Refining Company, at New Orleans, La.; new power house and boiler plant for the Hackensack Gas and Electric Company ,at Hackensack, N. J.; a large foundry for the Bagley & Sewall Company, at Watertown, N. Y.; a large machine shop for the Granger Foundry and Machine Company, at Providence, R. I.; an iron bridge, consisting of five spans of 200 feet for Penobscot County, Me.; a new carshed building for the

Third Avenue Railway Company, at Harlem River, N. Y.; three large buildings for the Standard Oil Company, at Constable Hook, N. J.; a new forge shop for Pratt & Whitney Company, at Hartford, Conn.; a new storage house for Bradley & Hubbard, Meriden, Conn.; a new tube plant for the Coe Brass Manufacturing Company, at Torrington, Conn.; a large extension to a producer house for the Solvay Process Company, at Syracuse, N. Y.

P. & B. THE WORLD OVER.

The Standard Paint Company's products are gradually but surely gaining a foothold wherever civilized man is settled, and Mr. R. W. Shainwald's recent trip abroad has resulted in the establishing of a number of agencies in European countries, through which the company's products can be secured direct. We have before us a circular done in choice Dutch, extolling the virtues of the various P. & B. compounds, and materials, which ought to prove convincing to our friends in the Low Countries. The Holland P. & B. agency is located at Hendrikkade, 21, Amsterdam.

A SAMPLE CARD OF MICANITE INSULATION.

The Mica Insulator Company, sole manufacturers of "Micanite," 218 Water street, New York, with factories at Schenectady, N. Y., and London, England, are sending to the trade a large sample card, handsomely got up, showing samples of Micanite commutator segments, rings, and slot insulation, for standard railway motors and power generators. Micanite and Empire insulating cloth and paper are shown in nine different grades, which are used largely for insulating armature cores and fields. In circular form, at the top of the card, appears the name of the company, and printed in red is the trade-mark, "Micanite, Perfect Insulator," at the right of which is the statement that manufacturers of electric light and power machinery have adopted Micanite as the standard insulator, and that estimates will be cheerfully given on insulation for special designed machinery when sketch or blue prints are furnished. The lower part of the card is given up to the list of agencies in the principal cities who carry a stock: Chicago, W. H. Sills & Co.; St. Louis, A. S. Partridge; Cincinnati, Sinclair Randall; Cleveland, the Cuyahoga Supply Company; San Francisco, J. W. Brooks & Co.

On the back of the card appears a description of the different lines of insulation that the company manufactures. This card has been gotten up at considerable expense, and has been sent to all manufacturers of electrical machinery, electric repair companies, and street railways in the United States, and is highly appreciated. The company is enjoying an excellent trade on their Micanite, which has become known as a standard insulation, both in this country and in Europe.

RICE & SARGENT ENGINES FOR THE BOSTON WEST END.

The West End Street Railway Company, of Boston, Mass., operating the largest street railway system under one management in the world, and using engines of various makes aggregating 20,000 horse-power, have contracted with the Rice & Sargent Engine Company for two cross-compound engines, to be direct-connected to electric generators.

These engines were selected in competition with the leading engine builders of the country, and their general dimensions are as follows:

Indicated horse-power, each engine		1,500
Diameter of high-pressure cylinders	inches	26
Diameter of low-pressure cylinders,	"	50
Length of stroke	"	60
Number of revolutions per minute		80
Steam pressure per square inch	lbs.	150
Diameter of flywheels	feet	24
Weight of flywheels	lbs.	120,000
Diameter of shaft in wheels	inches	24
Diameter and length of main bearings	"	22 x 38

The rims of the flywheels will be composed of forged steel, according to a new design, originating with the Rice & Sargent Engine Company, and the wheels will be practically indestructible.

Jet condensers and air pumps, driven by independent engines, will be used. Reheating receivers will be placed between the cylinders, and the piping will be arranged so that either cylinder of either engine may be run alone if desired.

The design is an unusually massive one, even for street railway work, which is responsible for much of the increase in weight of modern engines.

THE MANUFACTURERS' ADVERTISING BUREAU.

The Manufacturers' Advertising Bureau, Benj. R. Western, Proprietor, which has been located for a number of years at 111 Liberty street, New York City, will remove about April 15 to more commodious quarters at 126 Liberty street. This concern is widely and favorably known throughout both this country and abroad. It takes entire charge of the newspaper work and advertising for manufacturers, who desire to have this very important department of their business conducted with the greatest convenience and profit, free from personal worry. The bureau handles almost exclusively concerns who advertise in the trade journals, Mr. Western being a recognized expert in advertising media of this character, and has established a reputation for commercial integrity and scrupulous attention to the interests of its clients, of which it may well feel proud. A large number of the leading machinery concerns in the country entrust their advertising to the care of this institution. It is because of a growing need for better facilities to transact its business that the change from 111 to 126 will be made.

COOK-STODDARD MFG CO.

The Cook-Stoddard Mfg. Co., makers of gas and gasoline engines, have recently added to their factory at Dayton, O., a department for the manufacture of electrical machinery. They will build electric generators and motors of all sizes. Mr. Shawhan, formerly of the Shawhan & Thresher Electric Co., is connected with them, and will have charge of the work in this new and important department. The company propose to turn out the best apparatus, and will be glad to quote on orders.

WESTERN NOTES.

THE SOUTHERN ELECTRICAL SUPPLY COMPANY, of St. Louis, have recently removed from their old address at 11 North Seventh street, to new quarters at 10, 12 and 14 South Seventh street, where they have opened a very handsome store, which is stocked with a fine variety of electrical supplies, including the well-known Okonite wires and cables, interior conduit specialties, and Lundell motors. Mr. C. E. Sharpe manages the business of this company, and deserves to be congratulated upon the successful manner in which he attends to the welfare and improvement of the concern.

THE ELECTRIC APPLIANCE COMPANY has been fortunate in securing some nice contracts for bare copper wire, acting as Western selling agents for the Taunton Copper Manufacturing Company. The product of this mill is well known as a particularly high grade article, and the Electric Appliance Company hope to make it one of their leading specialties.

ADVERTISERS' HINTS.

KENNEDY & DU PEROW, Washington, D. C., are now agents for the Kerite wires and cables.

THE WESTINGHOUSE MACHINE COMPANY offer some interesting information regarding their inspection department. The conditions there prevailing are most exacting in every detail and should suffice as a guarantee of thorough workmanship and first-class material.

THE WATERTOWN STEAM ENGINE COMPANY are now represented in New York, Boston, and Philadelphia. Any communication to any of these offices will receive prompt and careful attention.

THE ELECTRIC APPLIANCE COMPANY are selling from a complete stock of incandescent lighting supplies, as well as all the latest novelties and staples in the supply line.

THE INTERIOR CONDUIT AND INSULATION COMPANY, in a letter to the trade, offer some suggestions well worthy the consideration of central station men.

THE MICA INSULATOR COMPANY briefly describe the De Ferranti alternator at Deptford, England, and it plainly shows how important a part Micanite forms in the construction of a dynamo.

ALEXANDRIA, IND.—The Stillwell-Bierce and Smith-Vaile Company of Dayton, O., have installed a plant for the water-works system of this city, comprising two duplicate pumping engines, each of 2,000,000 gallons capacity every twenty-four hours. The plant is also equipped with the Stillwell heater, filter and lime extractor. The official tests have, as usual, proved very satisfactory.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. APRIL 1, 1896. No. 413.

Electric Transportation.

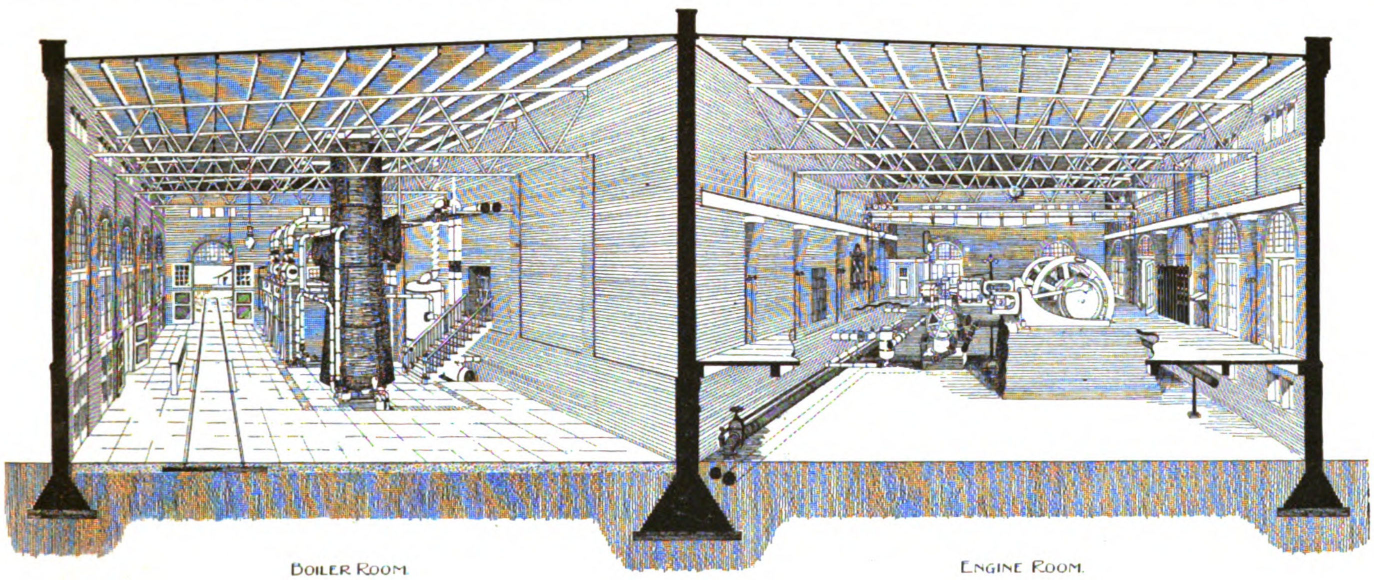
THE ELECTRICAL EQUIPMENT OF THE ORLEANS RAILROAD, NEW ORLEANS, LA.

THE Orleans Railroad was organized in 1867 at the beginning of the political reconstruction period in the South. It stands as one of the first of the industrial undertakings which have, in the last thirty years, accomplished so much in the development of the natural resources of Louisiana. This road has been owned and operated from the beginning by French-Americans, or Creoles. All of its lines extend entirely through the north side of New Orleans, or what was the old French city, and it touches at many of its most interesting and profitable traffic points. Owing to the narrow streets (which average about twenty-three feet from curb to curb) almost the entire line is laid out in single track. The illustrations in this article show some of the streets occupied.

Among the distinguishing features of the road may be mentioned the terminus and stand at Clay Statue, which is the business center of the city and by far the best traffic point possessed by any railway company in New Orleans. Other terminal points are the quaint and picturesque old French market, situated on the Mississippi River, the fair grounds at Sauvage street, the City Park, and the Metairie cemeteries. The fair grounds contain an exceptionally fine race track, on which, during 100 days of the winter season, the Crescent City Jockey Club conducts the series of races so well known in all sections of the country.

The Orleans Railroad Company adopted electric traction in order to compete successfully with other roads recently equipped. Until submitted to this unequal comparison, it had paid substantial dividends for a number of years. After a conservative discussion, the stockholders appointed a construction committee, consulting engineers were engaged, and bonds were issued to provide funds for the work. Since then the construction has been accomplished in the most expeditious manner. A statement of the method employed in the building of this road is interesting, because typical of the most approved method of recent engineering practice. Plans and specifications were prepared by the engineers, bids obtained from the best contractors in each line, and contracts let upon each item. Each contract had its accompanying plans and specifications, and the work was constantly under critical inspection and supervision by the engineers. The contracts were carefully drawn so as to be mutually exclusive, but together forming the complete construction. In this way, the contractor upon each particular part of the construction was a specialist in that line, so that the resulting work was done to the best possible advantage and the middleman's profit of a general or "bulk" contractor was saved to the company. Material and equipment were purchased at the lowest ebb of panic prices, and it is doubtful if there is a road more cheaply equipped for the same grade of material than this one.

A list of the contracts necessary for the complete equipment of this railway follows. With the exception of a few special features peculiar to New Orleans, this list includes all the items necessary for first-class electric railway construction:



SECTIONAL PERSPECTIVE OF BOILER AND DYNAMO ROOM, ORLEANS RAILROAD CO.'S POWER HOUSE.

Contracts for the Electrical Equipment of a Horse Railway.

Preliminary—

Real estate for power house 1
Removal of old buildings on this site 2
Water supply, driving artesian well 3

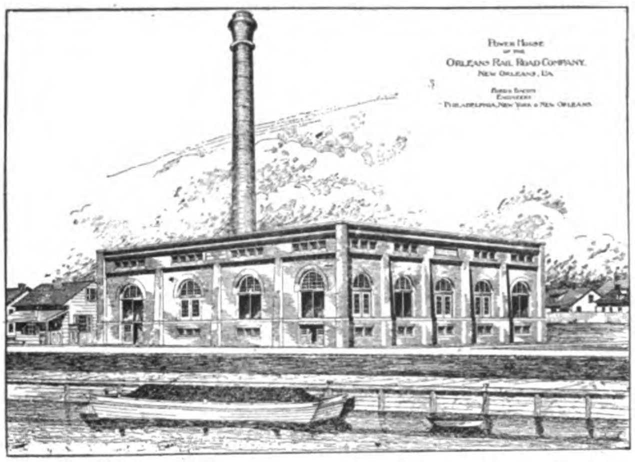
Power House—

Steel trusses and roof framing erected 4
Masonry, brickwork, carpentry and finish entering into foundations and building proper 5
Foundations for stack, boilers, engines, generators, condensers, pumps and piping 6
Boiler setting and stack lining 7

Power Machinery—

Self-supporting steel stack, flue and breeching, erected 8

Boilers erected 9
Engines erected 10
Generators and switchboard erected and connected........11
Air pumps and condensers erected 12
Feed pumps, delivered 13
Feed water heater, delivered 14
Complete steam, water, drip and blow-off piping, erected, including separators, oil purifier, gauges and gauge boards, valves, pipe covering, fire apparatus, erection of feed pumps and heater, and painting of all machinery......15
Traveling crane and track erected 16
Coal-handling apparatus 17
Arc lamps, fixtures and lighting wiring....................18



Power-House of the Orleans Railroad Co., New Orleans. View from River.

Car Equipment—
Trucks, delivered at car factory 19
Motor equipments, mounted at car factory 20
Car bodies, complete with fenders, registers, etc., delivered with motor equipments and trucks 21
Tower wagon, delivered 22

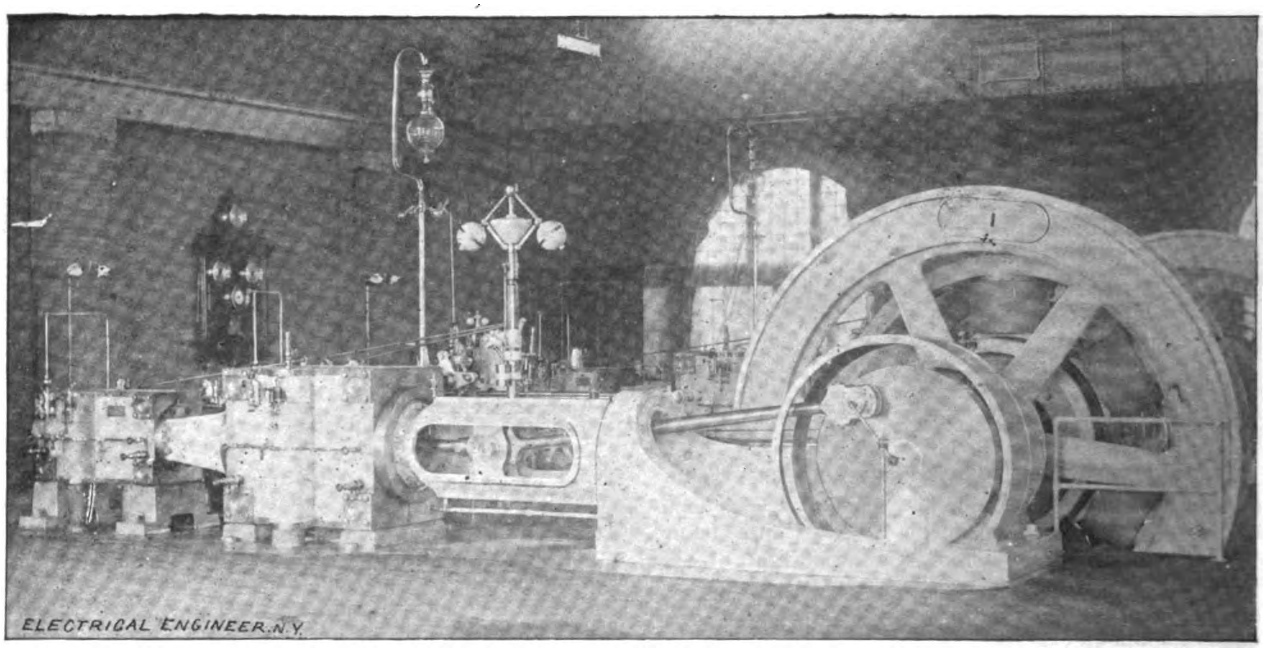
The names of the principal contractors were as follows:

Contract No. 4, roof trusses, contractor, Gillette-Herzog Co.
Nos. 5, 6, 7, 23, building and foundations, Chas. Garvey.
No. 8, stack and flues, Lewis Metesser.
No. 9, boilers, Heine Safety Boiler Company.
Nos. 10 and 12, engines and condensers, E. P. Allis Company.
Nos. 11 and 20, generators and motors, General Electric Co.
Nos. 13 and 14, feed pumps and heater, Smith-Vaile Co.
No. 15, piping, Benj. F. Shaw Co.
No. 16, crane, Brown Hoisting Co.
Nos. 18 and 27, overhead line and wiring, Creaghead Engineering Co.
No. 19, trucks, Baltimore Car Wheel Co.
No. 21, car bodies, J. B. Brill Co.
No. 25, rails and special work, the Johnson Co.
No. 26, track construction and paving, C. E. Loss & Co., and C. B. Fisher.

Power Plant.—The power plant is situated on the Carondelet Canal, or Old Basin, convenient for coal and condensing water and central to the feeder system. The location of the building upon the lot is such as to provide a driveway all around it with space for rear extension. The building design secures an ample supply of air and light without the objectionable features of a monitor roof construction. The absence of snow renders a flat roof most desirable for Southern climates. Large doorways sixteen feet in height open the three outer walls of the boiler room to ventilation and light. Broad casement windows secure the same advantage for the engine room. The engine and boiler rooms are each 48 feet by 82 feet interior dimensions. An eight-foot basement under the engine room provides space for separators, receivers, condensers, piping, and foundations. The front and sides of building and the engine room interior are faced with salmon-colored pressed brick. The trimmings are in limestone. A Fletcher roofing is applied to matched pine roof boards. Steel trusses and framing support the roof boards. The engine room floor is of mill construction. The boiler room floor is Schillinger pavement on eight-inch concrete foundation.

The subsoil consists of a black alluvial clay strewn with cypress stumps. All foundations for buildings and machinery are floated on a cypress plank flooring six inches thick and wide enough to support the load without settling. The walls are battered out to bear on this flooring. Dyckerhoff Portland cement is used in all underground work for concrete and brickwork.

An artesian well furnishes, when pumped, 345,000 gallons



Tandem Compound Condensing Engines in Orleans Railroad Co.'s Power House, New Orleans.

Car House—
Raising roof, renovating horse car barns and building pits..23
Repair shop tools 24

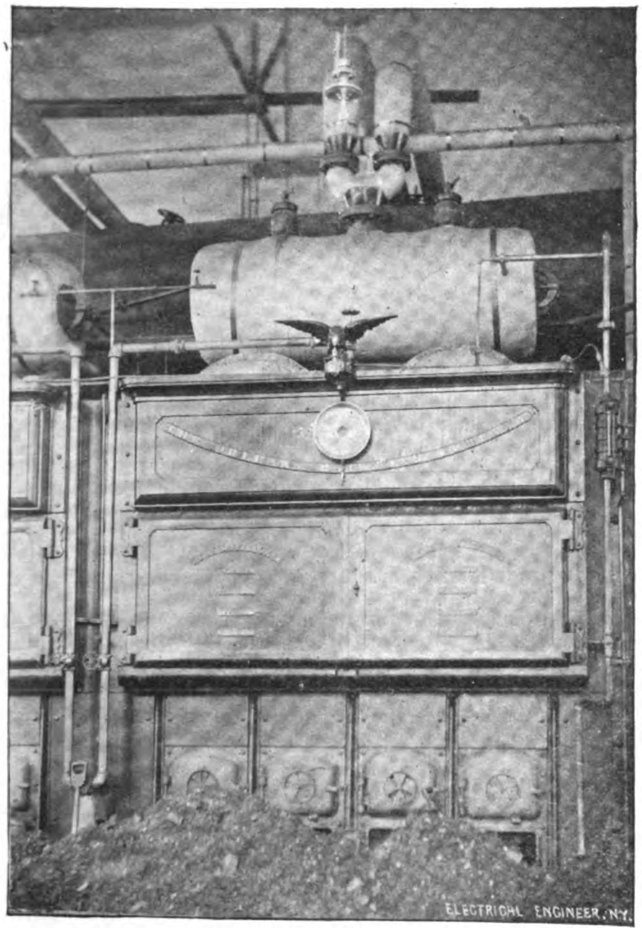
Line Work—
Rail material and special work, delivered 25
Track material, track construction and paving 26
Overhead line material and construction 27

per day. This water is used for condenser injection and feed. It contains a large proportion of carbonates which are precipitated in the open feed water heater.

The boiler room is designed for 1,000-horse-power water tube boilers in two batteries, half of which is at present installed. A self-supporting steel stack with breechings and flue connects to the boilers. The stack foundation is of concrete, 22 feet by

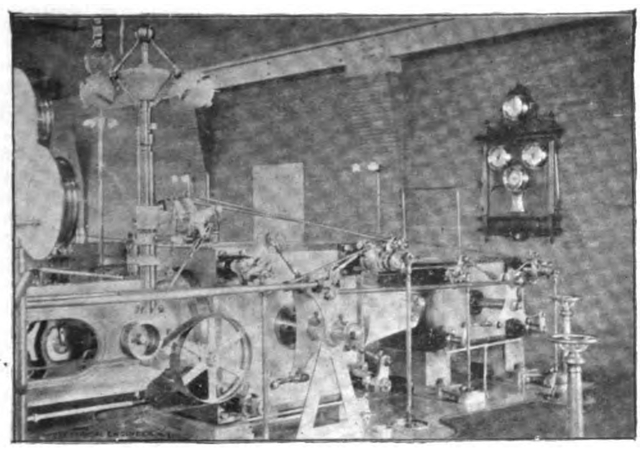
22 feet by 8 feet, entirely below the floor of the boiler room. Where the flue enters the stack a large reinforcing ring is riveted.

The engine plant is designed for 1,200 horse-power of tan-



A Heine Boiler Unit in Orleans Railroad Co.'s Power House.

dem compound condensing Corliss engines in three units, two of 300 horse-power and one of 600 horse-power. The two 14 x 26 x 36 engines now installed are direct connected to 200-kilowatt multipolar generators of the ironclad type. Each machine will run twenty-five single-motor cars, owing to the absence of grades on the line. These engines run at 120 revolutions per minute. The action of the valve gear and dash



Improved Corliss Valve Gear.

pots at this speed is most satisfactory, a result obtained by double porting the valves and lightening the moving parts, as seen from the above illustration. The exhaust valves in the low pressure cylinder are operated by a separate eccentric to admit of a wide range of cut-off.

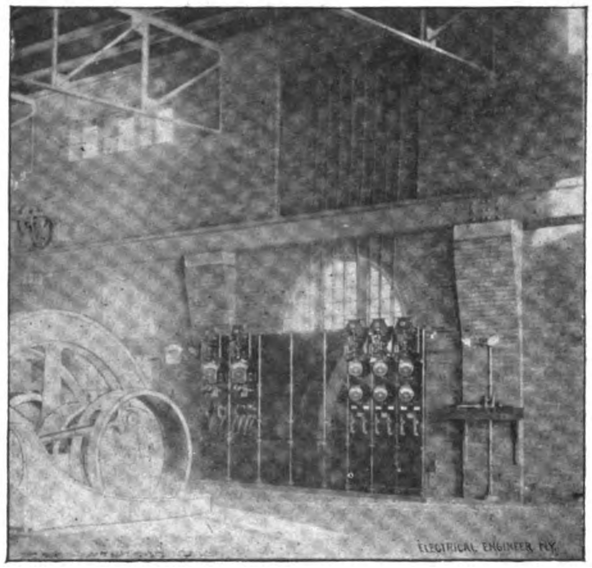
An independent vertical flywheel air pump and condenser are used with each engine. All the main valves of the condenser and engine piping are connected with valve stands in the engine room.

A standard black enamel slate panel switchboard is used with provision for two generators and six separate feeder circuits. Blank panels are installed for future equipment. Weston meters and Carpenter enamel rheostats are used on the board.

Individual gauge boards are provided for each engine, and a main board for the station. Crosby steam gauges are used.

The Davis system of duplicate high pressure steam piping is used. Each of the two mains is of such a size as normally will require the use of both headers and both leaders for any given engine or boilers. In case of necessity, one-half of the system is shut down, and the other half forced during the stoppage. In the usual duplicate systems where one pipe line is always idle, the leakage is generally sufficient to keep the idle main at the temperature of the live steam and makes it a radiating surface. This latter duplicate system therefore contains 43 per cent. more exposed live steam areas than the Davis system. The large duplicate system is also difficult to operate quickly in case of accident, on account of the sticking of valves, and has also the objection of almost prohibitive first cost. All of which difficulties are, it is said, overcome in the smaller system.

The pipe fitting of this plant also includes condensing



The Switchboard, Orleans Railroad.

and exhaust systems, feed water and purifying systems and drip and blow-off systems. Extra heavy wrought iron pipe is used in the live steam system, which is designed for a working pressure of 150 lbs. per square inch. Long radius bends take the place of fittings wherever possible. Copper bends occur where necessary to provide for expansion. Drips from all live steam mains are returned to the boilers. Valves, flanges and fittings in the live steam pipes are of the Chapman high-pressure standard. All joints are flanged with pipe screwed and peaned. The water piping is so arranged that either canal or well water can be used for condensing or feed. The feed is drawn from the hot well of the condenser, passed through the open heater and into the boilers at a temperature of 200° Fahr. A double covering of asbestos and hair-felt is used for all live steam surfaces.

A ten-ton traveling crane with hoist runs the length of the engine room.

The interior finish of this plant has been carefully planned. Engines, generators and air pumps are painted with a white enamel and simple gold striping. The railings, arc light fixtures, gauges, lubricators, etc., are all in nickel. The crane track, crane and trusses are a light straw color. The roof boards are in natural finish, varnished.

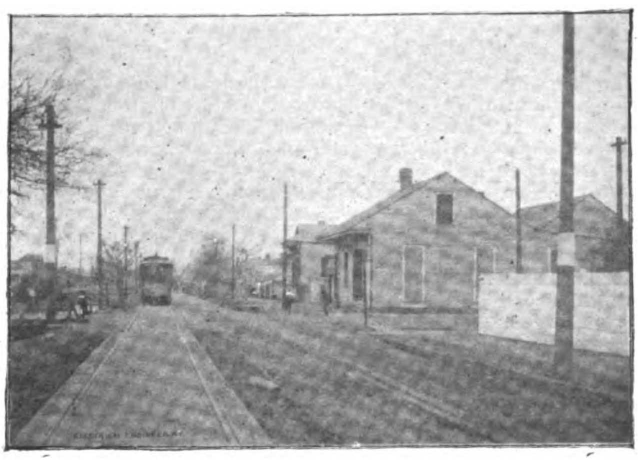
The Orleans power plant is considered by railway authorities to be one of the most efficient and carefully designed stations in the country.

Track Work.—The style of construction is that which has been found best adapted to New Orleans soil, consisting of a layer of one-inch cypress planking, extending over the entire subgrade. Upon the planking is placed four inches of Rosetta

or Bartlett gravel. This gravel has in its composition a sufficient amount of iron ore compounds to make it under pressure a concreting substance. After the track has been placed on 6 x 8 x 8 ties and the gravel thoroughly tamped, six inches of concrete is rammed between ties and between tracks. The paving at the Clay Statue consists of imported Belgian blocks on a two-inch sand cushion and concrete, as previously stated. The interstices between the blocks are filled with Assyrian asphalt. The same substructure continues throughout the work, but the pavement changes according to the location, consisting variously of large square granite blocks, cobble stone and planking. Where square block pavement is used, the rails are placed on five-inch by nine-inch stringers, which rest upon ties, the planking, ties and stringers being of cypress. The ties are placed twenty inches on centers at the joints, and at other points thirty inches on centers. All joints are secured by twelve one-inch bolt joint plates, the joints being suspended. The abutting ends of rails are placed in contact, and the joints are placed exactly opposite. Tie rods are spaced six feet apart throughout. The rails and special work installed on the Orleans road are of nine-inch girder, 90 lbs. per yard, and have proved most satisfactory in every particular. The bonding of the rails is what is known as the triple laced bond with channel pins, and the greatest care was taken to make this perfect.

View Showing Pole and Line Construction on Narrow Streets.

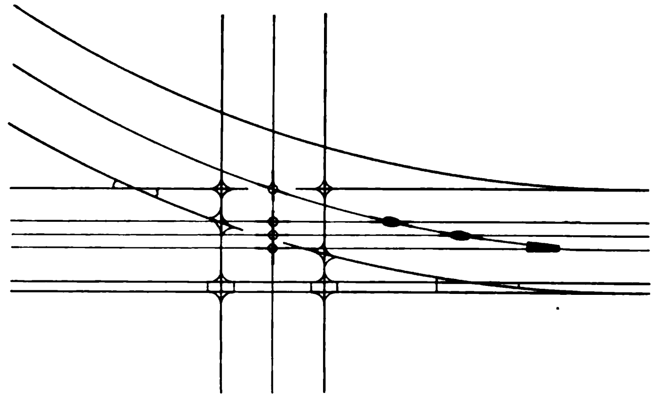
Overhead Line Work.—The permanent and substantial style of overhead construction is shown in the illustrations. It may be said that the greatest variation of pressure over the entire line is about fifty volts.



Plank Road Track in the Outskirts.

On the narrow streets bracket construction as illustrated is used throughout. The hangers are of special design, double insulated with flexible link joints. The section of line construction on Canal street is probably one of the most interesting and complicated in the United States. Canal street is the principal shopping and business center of the city, and the one street upon which all of the street railway companies operate. The total width of the street is 135 feet between curbs. It contains a "neutral ground," or continuous park, from the river front to the new basin. All railway tracks on the street are placed on the neutral ground, and the section between the river and Rampart street is the principal terminus of all the street railway lines of the city. There are in place now five continuous tracks. The three center tracks are used exclusively by the New Orleans Traction Company. The two outside trunk tracks, laid in double gauge, are owned by the Canal and Claiborne Railroad Company, who lease rights to operate at a fixed trackage to the Orleans Railroad Company, to the New Orleans and Carrollton Railroad Company, and to the St. Charles Railroad Company. Each of these companies has its individual trolley wire, and it is due to this and the fact that the New Orleans Traction Company continually crosses the trunk lines that the work becomes so complicated. Our diagram shows the ten trolley wires in position. The distance between trolley wires over the same track is eight inches. The poles are thirty-two feet in length, weigh 1,200 lbs., and are placed ninety feet apart. Bracket construction was used to make the structure reliable. If all wires were placed on a single span, the breakage of one of the spans would disable the entire railway traffic of the city. All line material is of special design. More than fifty specially designed insulated crossings are now being erected. All the poles are set in Dyckerhoff cement concrete in proportions of 1, 2, and 3. This work was designed and erected under the superintendence of Ford & Bacon, for the Orleans Railroad Company, the Canal and Claiborne Railroad Company, and the New Orleans and Carrollton Railroad Company. The New Orleans Traction Company and the St. Charles Railroad Company also use this overhead structure.

Car Equipment.—During the present summer and fall the road will operate from twenty-five to thirty cars over their present tracks and extensions. The Brill cars have 18-foot and 20-foot bodies. The interior finish is in natural ash and holly wood, obtaining a cool and light effect. The lighting consists of eleven lamps, two on platform, three in monitor roof and three on each side of the car at the upper window line between the windows. This has helped materially to make the cars popular, as one can read in any position. The equipments are of single G. E. 800 motors. All seats are of the Hale & Kilburn spring rattan pattern.



Overhead Line Construction on "Neutral Ground."

The officers of the company are: P. Cougot, President; James Pollock, Secretary, and H. J. Malochée, Superintendent. Plans and specifications for the entire construction and equipment were furnished by Ford & Bacon, engineers, of New York. Philadelphia and New Orleans, under whose superintendence the various contracts were executed.

$3,000 BONUS FOR ATLANTA STREET CAR MEN.

The Consolidated Street Railway Company of Atlanta has distributed $3,000 in bonuses to its street car men in sums ranging from $41 down to $5. This bonus was put up in July, in order to encourage the conductors and motormen to better efforts and more care in discharging their duties, both to the company and the public. Those who were to be entitled to a share in the fund should be the men who had been with the company from July to January 1.

A system of fines was also inaugurated against the men for failure to carry out the specific rules of the company. All fines were charged against the men who violated those rules, and the fines made up a fund; both were distributed on a graduated scale.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—VI.

BY

Wm. Baxter, Jr.

THE cost of repairs to locomotives is great, and in this direction electric motors would make a decided saving. Very few are aware of the magnitude of the cost of maintenance of locomotives, although it is generally understood that the figures are high. A few facts, or, more properly speaking, data, taken from official records, will throw light on the subject.

In the State of Massachusetts, the average cost per year of repairs per locomotive is $1,160, and amounts to about 46 per cent. of the coal bill. On the New York Central Railroad, the repairs to locomotives are given as $1,580,660.01. The amount expended for coal is $3,031,749.77, from which it will be seen that in this particular case the percentage runs up to about 50. As the total operating expenses for the same year are $30,631,732.87, it will be seen that the cost of keeping the locomotives in repair amounts to over 5 per cent of all the other expenses combined.

On the Philadelphia and Reading Railroad the cost of repairs to locomotives is $883,463.47, and the total expenses of operation $11,403,307.37, so that the percentage of repairs to total expenses is over 7 per cent. The Pennsylvania Railroad spends $2,896,735.12 for repairing locomotives out of a total expenditure of $41,003,800.20, which is about 6¾ per cent. The coal bill on this road for the same year is $3,724,481.14, from which we can see that on the Pennsylvania Railroad the cost of keeping locomotives in repair equals about 78 per cent. of the coal bill.

From the few facts given above, it is evident that in the matter of repairs to locomotives there is room for effecting a large saving, as this item will amount on an average to not less than 5 per cent. of all the other expenses. That the cost of keeping motors in repair would fall far below this figure, will be conceded by every one informed on the subject.

Some years ago, Mr. O. T. Crosby, in a very able article on the "Limitations of Steam and Electricity in Transportation," took up this subject and showed by a very logical course of reasoning that the cost of repairs to motors would not be more than 30 per cent. of the amount expended on steam locomotives. His basis of reasoning was exceedingly conservative, and it can be safely assumed that the saving claimed would be more than realized in practice.

Not only in the item of locomotive repairs could the electric system effect a saving, but also in the cost of maintaining the track. This statement may seem unreasonable at first sight, but a brief explanation will show that it is not so. A locomotive is an unbalanced machine and cannot be made otherwise. This fact is well known to steam engineers. The moving parts of a steam engine can be balanced either in a vertical or horizontal direction, but not in both. A locomotive can be balanced vertically by placing a counterbalance weight in the driving wheel, opposite the crank about equal to the crank pin, and half the connecting rod; but to balance it horizontally it is necessary to make this weight equal all the moving parts, that is, the piston, piston rod, crosshead, connecting rod, and crank pin. If the latter weight is used, the machine will be more out of balance vertically than if no weight at all were used; therefore, the best result is obtained by taking a weight that overbalances vertically and underbalances horizontally. As the engine is out of balance vertically, the result is that the track is subjected to a series of shocks, from the effect of which the ties soon become loose in the ballast. As the two cranks are set 90 degrees apart, the unbalanced horizontal weight tends to first swing the locomotive to one side and then to the other. The effect of this is to loosen the spikes, and spread the rails.

As an electric motor is a perfectly balanced machine, it would not produce any of the effects above described on the track; therefore the wear and tear would be very much less. That the difference would be great, will be realized when we consider the difference between a line of shafting on which all the pulleys are balanced and one on which they are not, even if running at a moderate speed. In the former there is no wear except in the bearings, but the latter will soon shake the hangers loose, and will be a constant source of trouble and expense.

The locomotives are not responsible for the whole deterioration of the track, but are the cause of a very large proportion of it, and it is safe to say that the reduction in the cost of maintenance of roadway, due to the absence of the racking effect with electric motors, would be very noticeable.

In viewing the various items in which it has been shown that a saving can be effected in the operating expenses of a road by adopting electricity, we find that we are not confined to the reduction of the coal bill alone. We can also reduce the labor account by doing away with the expense of firemen, by entirely eliminating the expense of maintaining coal and water stations, and by reducing the number of men required to operate the signalling system. We can still further reduce the expenses by the difference between the cost of repairs to locomotives and electric motors, and finally by the reduction in the cost of maintenance of roadbed.

In pointing out the various ways in which the coal bill could be reduced, it was stated that the weight of motors required to haul a train would be considerably less than that of locomotives, and that as less weight would have to be drawn over the road, the power required would be less, and hence the coal consumption less.

Now let us consider to what extent the weight could be reduced. If we were to assume that the steam locomotive must be replaced by an electric locomotive, we would then say that the saving would be the difference between the total weight of engine and tender with an average amount of coal and water, in the latter, and that portion of the weight that rests on the driving wheels only. But it does not follow that the electric system should drop into the footsteps of steam, and replace the locomotive with a machine that would be its counterpart. When this phase of the question is given careful consideration we find that there is every reason why a steam locomotive should be a separate machine, while there is none whatever to justify the making of an electric motor such. A locomotive must have a boiler to supply the steam, and also a water tank and coal bunker. Those parts take up so much room that they must necessarily be made in the form of a separate machine.

But even in steam practice, when the power of the locomotive is small enough to permit it, the machinery is placed at one end of a car, as is the case in dummy engines. The use of a separate electric locomotive is unnecessary, and would only add to the cost of operation as well as to the initial cost of the road. There is ample space on the trucks of a full-size steam railway car, whether freight or passenger, to locate motors of sufficient capacity to do the heaviest work required in railway service. There is no valid objection to such an arrangement, while on the other hand there is every reason why it should be adopted. The weight of the car would give all the traction required, as it would be equal to the weight on the drivers of the largest size locomotives. The motors then could be designed so as to give the maximum output per unit of weight, and, as a result, not less than 5 per cent. of the weight of the steam locomotive and its tender would be saved. On a train like the Empire State Express, where the weight of locomotive and tender amounts to about 37 per cent. of the entire weight, this saving would amount to about 25 per cent. of the entire train.

In addition to the advantage gained by a reduction in weight, locating the motors under one of the cars would do away with the services of one man. An electric motor car, as already stated, can be handled perfectly by one man, but to guard against accidents should the man become disabled in any way, it would be necessary to have an extra man near by to take his place, if necessary. On account of safety, an independent locomotive would require two men. With a motor car such would not be the case. This car, in passenger trains, could be used for baggage, and the baggagemaster could be required to stay with the motorman while the train was in motion, so as to take his place if occasion should arise. The same arrangement could be made with freight trains by making the motor car the conductor's headquarters, and requiring the latter to act as substitute motorman.

Exception may be taken to the statement that by placing the motors on the trucks of a car fully 75 per cent. of the weight of a locomotive of equal capacity could be saved, since to effect such a reduction would require a very high output of energy per unit of weight in motors, more, perhaps, than could be obtained in practice. But any doubt as to the possibility of constructing motors that will fully carry out this assumption can be removed by an investigation of what has already been done in that line. The writer has devoted a large portion of his time during the past four or five years to the work of designing railway motors with special reference to obtaining a large output per unit weight. A 25-horse-power motor that was designed to be mounted directly upon the axle of a street railway car gave a horizontal effort of over 900 pounds when working at its rated capacity, and this could be increased to more than 1,800 pounds for a period of ten or fifteen minutes without danger of overheating. The weight of

the motor was less than 2,200 pounds. It was made for use on a truck having 30-inch wheels, and as it was considered that the lowest parts of the machinery should be at least four inches above the tread of the rail, the vertical dimension of the motor was kept within twenty-two inches.

With trucks of the size used for steam railway cars, very much higher results can be obtained. Not only are the wheels larger, but as the space between rails is not paved, the motors could be made of a height very nearly equal to the diameter of the wheels. Under such conditions the torque at the peripheries of the armature and wheels would be nearly the same, whereas in the case above cited, the armature was only nineteen inches in diameter; therefore the horizontal effort was less than two-thirds of the armature torque.

As a further proof of the possibility of obtaining all the power necessary to draw a train from motors weighing one-quarter of the total weight of a locomotive and tender of equal capacity, I will refer to a set of motors also designed by the writer that have been in use for several years on the Neversink Mountain Railroad, of Reading, Pa. These motors are mounted on trucks having 30-inch wheels. They are of the single-reduction type, and weigh about 2,200 pounds each. The motor car is thirty-four feet long and weighs 22,000 pounds; the trailers are thirty-four feet long and weigh 18,000 pounds. The road is a continuous up-grade for a distance of 3⅝ miles. The grades range from 1½ to 7 per cent., the average being about 3 8-10. The car equipped with these motors has on many occasions drawn up the hill, in addition to itself, a trailer, both fully loaded, the total number of passengers on both cars being 250 and 300.

A simple calculation will show the output of these motors under the above conditions. Taking the number of passengers at 275, and the average weight of each at 110 pounds, we have:

Total weight of passengers, 275 x 110 = ... lbs.	30,250
Weight of motor car .... "	22,000
Weight of trailer car .... "	18,000
Total .... lbs.	70,250

Assuming tractional resistance to be 12 pounds per ton, which is certainly low for this character of road, we would have:

Tractional resistance .... lbs.	421.5
Gravity resistance on 3 8-10 per cent. grade........ "	2669.5
"	3091.0

This is the average horizontal effort, and as the average speed is about 12 miles per hour, the energy developed amounts to about 90 horse-power. To mount the 7 per cent. grade requires an effort of 4917.5 pounds, which makes the maximum horizontal effort 4917.5 + 421.5 = 5,339.0 pounds. As these motors are of the single reduction type their performance cannot be taken as representing what can be done with motors mounted upon the axles, but the performance of such a machine can be estimated with a very fair degree of accuracy by making the proper allowances for the difference in conditions. Thus, as these motors are geared down four to one, the torque, or horizontal effort, if the armatures were on the axles, would be one-quarter of that shown above. It would, in fact, be somewhat more, because the gears absorb in friction fully 6 per cent. Making this allowance, we have:

$$\frac{3091 + (3091 \times .06)}{4} = 819. \text{ and } \frac{5339 + (5339 \times .06)}{4} = 1420.$$

That is, 819 pounds of the average horizontal effort if the armatures were mounted on the axles, and 1,420 pounds as the maximum under same conditions.

AN ELECTRIC RAILWAY FOR CUBA.

Ex-Senator E. H. Hammond, of Orlando, Fla., and Colonel T. J. Appleyard, of Sanford, Fla., have been in Cleveland in consultation with S. T. Everett, of the Everett Electric Railway syndicate. As a result a company will be formed in Cleveland, having for its object the construction of electric street railways in Havana as soon as the war is over, and the ultimate extension of the system throughout the island. Such railroads have been impossible heretofore, owing to the oppressive taxes levied by Spain. The gentlemen interested say that even if the insurgents are not victorious they have assurances that Spain will mitigate many of the conditions which have caused trouble and prevented business progress in Cuba.

THE JOHN SCOTT MEDAL.

Mr. A. Langstaff Johnson, of Richmond, Va., has been awarded by the Franklin Institute the John Scott legacy medal and premium for his bonding joint for electric railways.

TESTS OF A 10-CAR ELECTRIC RAILROAD.

BY JOHN F. VAUGHAN.

THE electric street railway from which these figures were taken consists in a newly built line of single track, ten miles long, running north and south across an open and somewhat hilly country, and an eleven-mile loop, several years old, leaving the main line near the south end and meeting it again about two miles from the north end. A short spin leaves the line near the south end.

The power for this road is derived from a station about three-quarters of a mile south of the south end, occasioning about 25 volts drop before the track is reached, although the station regulation is good. The data may be tabulated as follows:

Miles of track	22½
Number of cars in service	10
Car mileage per day	1,750
Average speed (including stops) .... miles	9½
Average current per car (during run) .... amperes.	20
Watt-hours per car mile (at station)	1,500
Watt-hours per car mile (by wattmeter on car)	1,090
Station potential	560
Average potential on line	448
Maximum drop on line .... per cent.	49
Average feeder losses (calculated) .... "	14
Average ground losses (measured) .... "	15
Line efficiency (at present) .... "	71
Line efficiency (with good bonding) should be "	82
Maximum observed station load (clear cold weather, amperes	450

The bonding on the old line is destroyed in many places, showing over 50 per cent. of the total line resistance in places. The line leakage varied from 2 to 8 amperes, according to the weather. The heaters added, on an average, 8 amperes per car.

A striking example of the effect of the position of the station on the economy of distribution is seen by comparing the above figures with those obtained on the assumption that half the power be taken, as is proposed, from a lighting station between the proper center of distribution and the north end of the line. With the two stations and the same feeder system:

The maximum drop on line....................	22 volts = 3%
Average potential on line	volts 546
Average feeder losses	per cent. 3.1
Probable line efficiency	per cent. 96

JUNGFRAU ELECTRIC RAILWAY INTERNATIONAL COMPETITION.

THE Jungfrau Railway Commission, of Switzerland, has issued the programme of conditions of an international competition for the best solution of a number of questions connected with the construction and working of an electric railway up the Jungfrau. Prizes of a total amount of $6,000 are offered. The points to which attention is called are as follows:

I.—The Design of the Line.—(a) The section of the tunnel, without and with stone lining; the foundation and overhead construction, rails, rack-rail, switches and crossings; (b) the system to be adopted for the electric transmission of the power; equipment of the primary stations; system of distribution of the current along the line; protection against atmospheric disturbances; (c) the electric cars, with all the necessary safety devices; (d) designs for the station building and restaurant at Eigergletscher Station; (e) construction and equipment of the intermediate stations; (f) design of a Klubhütte shelter to take fifty persons at Mönchjoch Station; (g) elevator, about 100 meters high and 8 meters in diameter, provided with staircase, at the summit of the Jungfrau.

II.—The Construction of the Line.—(a) The boring of the tunnel; electric drilling machines, blasting material, ventilation; (b) the removal of the spoil; (c) precautionary measures for the maintenance of health and life of the workmen, patterns of movable barracks.

III.—The Working of the Line.—(a) Plans for insuring under the given conditions a continuous working of the line; (b) electric lighting of the tunnel, cars and stations; (c) electric heating of the cars and stations, precautions for the safety of passengers and working staff.

One or more of the above points may be dealt with by a competitor or several competitors collectively. Further suggestions likely to be of advantage to the Jungfrau Railway undertaking are also invited.

The Scientific Commission, with the assistance of experts, will settle the award of the prizes. The results will be pub-

lished. Upon the prizes being distributed the Jungfrau Railway Company will acquire the right to use the plans obtaining prizes without further compensation. The commercial copyright will, however, remain the property of the author. Rejected papers will be returned.

The following data are given: The maximum gradient of the line is 25 per cent. The gauge is 1 metre. The sharpest curve is 100 metres radius, and the maximum radius is 500 metres. The greatest width of car must be 2.5 metres, the greatest height 3 metres, the maximum speed 7 to 10 kilometres per hour. The water power at the disposal of the electrical plant is about 5,000 horse-power, and will be taken from the River Lütschinen. The distance between the power house and the starting point of the line on the Kleine Scheidegg is about 8 kilometres; from there to the tunnel entrance it is 2½ kilometres, and the tunnel has a length of about 10 kilometres.

Competitors must illustrate their schemes by drawings or models, and must also enclose estimates of costs. The latest date for sending in schemes is Aug. 1, 1896.

Further information may be obtained from Bureau der Jungfraubahn, Bahnhofstrasse 10, Zurich, Switzerland, where also general plans, the result of geological investigations and details of the water power available may be obtained.

The Scientific Commission of the Jungfrau Railway will consist of Professor Becker (Zurich), H. Brack, technical director of the North East Railway (Zurich), Professor Golliez (Lausanne), Dr. Maurer (Zurich), Dr. L. von Salis-Guyer (Basle), Dr. Schmid (Berne), Rev. G. Strasser (Grindelwald), E. Strub, railway engineer (Interlaken), Professor Walder-Meyer (Zurich), Professor Weber (Zurich), Dr. Wrubel (Zurich), and President Guyer-Zeller.

MORE ELECTRIC MOTORS FOR THE BROOKLYN BRIDGE.

At the meeting of the bridge trustees on March 23 the plans for the introduction of electric power on the railroad were outlined in this report from Chief Engineer Martin, which was received and approved:

"Since the last meeting of the board I have conducted a series of observations upon the operation of the motor car in use, with the result that it has been determined to use motors of 25 per cent. greater capacity than those on the present motor car and to somewhat differently arrange the electrical units in the power house and increase their capacity 20 per cent.

"With the equipment increased, as shown, the plant will readily do the switching of trains running on forty-five seconds headway, and in case of failure of the cable, it will be capable of running four-car trains at intervals of sixty seconds. With the transportation equipment, consisting of a double cable, gauntleted tracks, and the above described electrical plant, it seems to me that we shall be in an ideally perfect condition to carry absolutely the maximum number of passengers that the bridge railway can be made to carry. Although even the maximum carrying capacity of the bridge will in all probability never again be equal to or exceed the heavy demands made upon it during the rush hours, it will meet, as far as it is possible for this one bridge to meet, the ever-increasing demands for transportation between New York and Brooklyn.

"The plant required to put the bridge railway system in perfect condition will be a power house about 100 feet square, engines of a capacity of 2,500 horse-power, boilers sufficient to supply steam to them, electrical generators of about 1,600 kilowatts capacity, and with all the paraphernalia of a first-class power house. It is proposed to locate the power house on property owned by the bridge trustees and situated at the corner of Dock and Water streets.

"The car equipment will consist of four motors, each of which will be able to exert a drawbar pull of 1,500 pounds, and they will be arranged so that any number of them can be operated independent of the rest. All of the ordinary and well-tested devices will be installed to insure certainty and regularity in the operation of the electrical appliances.

"I have made an approximate estimate of the cost of the new power house and plant complete, and it will be about $300,000. I have made all estimates liberal, and feel sure that the figures given will not be exceeded. This does not include the new cars that will be required. Neither does it include the heating equipment on the cars for heating by electricity. The above estimate provides for the equipment of twenty cars."

At the next meeting the trustees are to submit the plans for the power house, and on their approval bids will be at once advertised for.

The Executive Committee reported that the contract for the equipment of twenty cars with electric appliances had been awarded to the General Electrical Company, at $3,645 each.

SALE OF THE CITY OF MEXICO STREET RAILWAYS.

The City and Suburban Tramway system of the City of Mexico was bought recently by Mr. H. A. Butters, representing London and South African capital. The purchase price is stated at $7,750,000, payable in installments, one of which is $6,000,000 in 6 per cent 20-year mortgage bonds. The system includes about 200 miles of steam and animal traction lines, and it is the intention to equip with electricity, using, perhaps, the drainage canal, for 6,000 horse-power. The consulting engineers are W. W. Page, of London, and T. W. Orbison, of the firm of O'Keefe & Orbison, of Appleton, Wis.

A TROLLEY ROAD FOR TEHERAN, PERSIA.

It is stated that the first trolley railroad in Persia will be built from Teheran to the summer resorts, about ten miles to the north of the city, where everybody lives during the hot season. The summer on the Persian plateau is very hot and dry, and it is only in the neighborhood of the mountains that Europeans can stand the great heat. A concession for ninety years has been granted to a German contractor, who will start the building of the road at once.

ELECTRICITY FOR ENGLISH LIGHT RAILWAYS.

At the London Imperial Institute, Mr. W. J. Brewer recently read a paper on "Light Railways; Their Construction and Working." After many years' experience in railways, he was convinced that there was nothing to compare with a properly-organized system of feeders for the main lines of railway. By the aid of electricity, it would be possible to supply both power and light, not only for the lines, but for the towns and villages on their route. The lines would be a means by which a system of telegraphs and telephones could be established at a slight expense, and they would add to the income. In his opinion, the new "autocar," in the interests of the agricultural classes, would never do the work of a light railway, simply because no road could ever equal the surface of a rail. It was absurd to argue that these feeder lines should be of the same gauge as the main lines. The loads on the cars of the feeder lines could be so arranged as to be moved from the feeder car to the main line car with the least possible amount of trouble or waste of time. As a motive power, he took his stand by electricity. The materials comprising the car, motors, standards for carrying the electric conductors, rails, and other necessary equipment, should be manufactured on the duplicating system, so as to reduce first cost and facilitate renewal.

NEWS AND NOTES.

PLATINUM IN NEW SOUTH WALES.

It is agreeable to note the well accredited statement that large deposits of this valuable mineral have been discovered at Fitfield, New South Wales. It has been known for several years that platiniferous lead existed, and the deposits have been worked, though only on a small scale. It is now found however, that the platiniferous lead is over a mile long, varying in width from 60 feet to 150 feet, and covered with from 60 feet to 70 feet of loam. The precious metals are practically confined to the bedrock and the drift for 3 inches above the bottom. Nuggets which weighed from a few grains up to 5 dwt. have been occasionally found. The crude metal contains about 75 per cent. of platinum, and realizes upon the field nearly $5 per ounce.

ELECTRIC PROPERTIES OF COMETS.

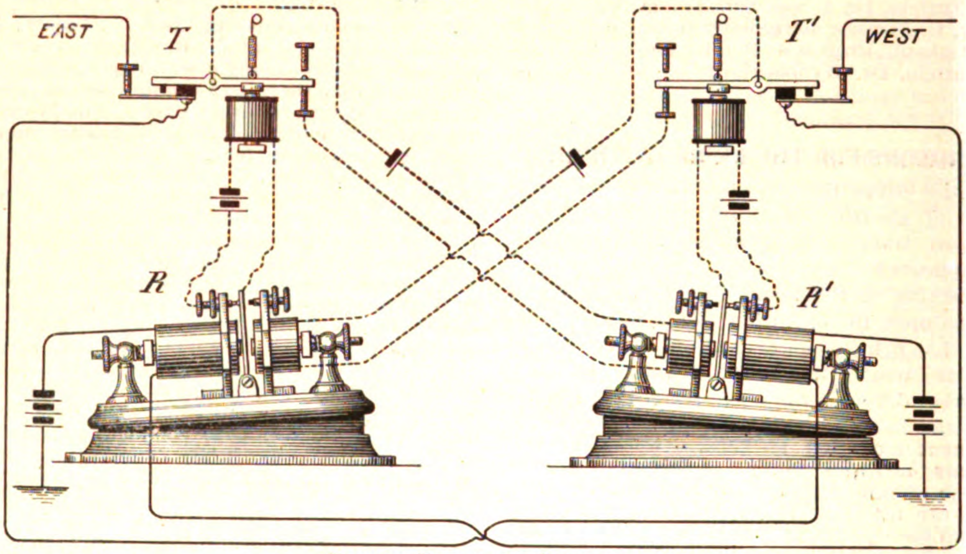
In a recent number of the "Astrophysical Journal" Professor Fessenden suggests that the ultra-violet rays falling upon that side of the nucleus which is turned towards the sun cause negatively-charged particles to be emitted, the nucleus remaining positively charged. Researches by Professor J. J. Thomson indicate that the solar chromosphere is negatively electrified; and the spectra of cometary tails, resembling as they do the candle spectrum, support the hypothesis of negatively electrified tails. There will, then, be four forces acting on the particles projected from the inner surface of the nucleus—namely, the solar electrical repulsion, the mutual electrical repulsion, the electrical attraction of the nucleus and gravitation. These forces will determine the form of the tail; and it would seem that all the special differences in comet structure are capable of explanation on the hypothesis. A solar potential of about 15,000 volts is apparently required.

Telephony and Telegraphy.

HORTON'S TELEGRAPH REPEATER.

MR. L. HORTON, JR., superintendent of the Philadelphia and Reading Railroad Company's telegraph system, has recently been granted a patent on a telegraph repeater, which has found great favor among telegraph men generally on account of its simplicity, compactness and effective working, and which has already been adopted by the Lehigh Valley Railroad, Philadelphia and Reading Railroad, and National Transit Company, and is in use on the lines of the Western Union Telegraph Company, Long-Distance Telephone Company, North American Telegraph Company, and Pennsylvania lines west of Pittsburg. The distinguishing feature of this repeater is the method adopted for preserving the continuity of the sending circuit while the opposite line is being repeated into, which Mr. Horton accomplishes in a remarkably simple and effective manner by the utilization of the force of gravity, dispensing with all extra armatures, springs or other mechanical contrivances, the holding force being obtained by the withdrawal instead of the application of a local current.

The principle and operation of the repeater will be readily understood by reference to the accompanying illustration in which T and T' are ordinary repeater transmitters of the usual form with front and rear contacts arranged for repeating into their opposite lines, and also for actuating the retracting magnets of opposite relays. R and R' are main line relays, differing from the ordinary relay only in the inclined base and the addition of the local retracting magnets which are placed directly behind the relay armature occupying the same relative position as the main line magnets in front and acting, when energized, upon the armature as a retractile force (in place of the usual spring) to draw it backward and away from its local contact when the main line current through the front coils is interrupted, and when demagnetized to prevent such movement of the armature which, under this condition, remains motionless upon its front or local contact regardless of the presence or absence of a current through the main line coils in front; the inclined base on which the relay rests causes the armature to retain its forward position by the force of gravity at such times as both sets of coils may be demagnetized, and thus keeps its neighboring transmitter closed.



Horton Telegraph Repeater.

These retracting magnets being adjustable with reference to their position with the armature, are drawn toward or away from the latter, as it is desired to increase or diminish their force upon it, in precisely the same manner as the tension of the spring in the ordinary relay is regulated; and it will be seen that this is the only part of the repeater requiring adjustment.

The arrangement of circuits, as shown in the diagram, is as follows: The eastern circuit is brought to the post of transmitter T, and from there when the transmitter is closed, through relay R' to battery and ground. The western circuit is brought to the post of transmitter T', and thence through relay R to battery and ground. Both lines being represented as closed, the action of the repeater is as follows: A distant office on the western line opening its key interrupts the current through the relay R, the armature of which is thereupon drawn away from its local contact by the action of its retracting magnet, permitting its neighboring transmitter T to open, which, in turn, opens first the local circuit of retracting magnet of relay R' and next the eastern circuit at its spring contact.

The opening of the extra local circuit demagnetizes the retracting magnet, thereby preventing any movement of the armature of relay R', which is held against its front or local contact stop by its own weight when the main line through the front coils is opened an instant later, transmitter T' being thus kept closed, preserving the local circuit through retracting magnet of relay R, and providing a path for the western circuit through spring contact of transmitter T', relay R and battery to ground to enable the distant western office to close relay R again.

When the western office closes its key the armature of relay, R, is again attracted forward, closing the local circuit of transmitter, T, which in turn closes first the eastern circuit at its spring contact and next the local circuit of relay R's retracting magnet.

The means employed for keeping the relays on either side closed during the time their respective circuits are being repeated into accomplishes the result most effectively without the use of extra armatures requiring special adjustment, the adjustment being thus simplified to that of an ordinary relay.

The advantages of this repeater are:

1. Its thorough efficiency as a repeater, the absence of all extra armatures and springs from the relay, rendering the latter extremely sensitive and permitting the closest possible adjustment of both relay and transmitter armatures, the play of which may be shortened up so that their motion is scarcely perceptible, which, together with the instantaneous application of the holding force, greatly increases the capacity of the repeater for rapid work. Any very marked decrease in strength of extra local current, which is fatal to the operation of most forms of repeaters, can be instantly and fully compensated for in this instrument by simply giving the adjustment screw of the retracting magnet a turn to bring it closer to the armature, and as the holding force is in no sense dependent upon the strength of current, any variation in the same can have no possible effect upon this function of the instrument.

2. The very small amount of attention required during its operation, the adjustment seldom requiring change, and the ease and simplicity of adjustment, which insures better results in the hands of ordinary operators than most forms.

3. Small amount of battery required with resultant economy in maintenance, one cell of extra local for each retracting magnet being sufficient as against six cells usually employed in the Milliken, for example, in addition to which it is found that the transmitters can be operated on less battery consequent upon their close adjustment. It is said that a saving of about ten cells of local battery can be effected at each repeater where this form takes the place of a Milliken repeater.

It will be readily seen that this repeater can be divided into half sets and operated in connection with duplex or quadruplex systems with the same facility as other forms not possessing its advantages.

LETTERS TO THE EDITOR.

ELECTRICAL INSURANCE RULES FOR STREET RAILWAYS.

"At the recent formation of the National Conference on Standard Electrical Rules, in common with the electrical interests, the American Street Railway Association was represented, and for the first time was consulted with regard to the various electrical rules now enforced by the insurance companies. The following committee was appointed to formulate a new code of rules to be submitted to the next meeting of the National Conference, June 25 and 26: Francis B. Crocker, chairman, representing American Institute Electrical Engineers; William J. Hammer, ex-officio President National Conference on Standard Electrical Rules; Frank R. Ford, American Street Railway Association; William H. Merrill, National Board of Fire Underwriters; Alfred Stone, American Institute of Architects; E. A. Fitzgerald, Underwriters' National Electric Association; William Brophy, National Electric Light Association; E. V. French, Associated Factory Mutual Insurance Companies.

The undersigned, as representing the American Street Railway Association, has been requested to secure suggestions from the members of the association, and from all other street railway companies, engineers and allied manufacturing interests, with respect to such changes or additions to the present rules that may seem advisable.

The importance of this work, in its bearing upon street railway construction and the opportunity now offered to street railway interests for the first time to participate in a movement in which they are so vitally concerned, should not be overlooked. The Committee on Rules depends upon the active co-operation of all parties at interest in order to secure a full presentation of all changes that might be beneficial in the formulation of a new code.

The present rules relating to electric railways are as follows:

Electric Railways.

"RULES FOR SAFE WIRING.

"37. All rules pertaining to arc-light wires and stations shall apply (so far as possible) to street railway power stations and their conductors in connection with them.

"38. Power Stations:—

"Must be equipped in each circuit as it leaves the station with an approved automatic 'breaker,' or other device that will immediately cut off the current in case the trolley wires become grounded. This device must be mounted on a fireproof base, and in full view and reach of the attendant.

"Automatic circuit breakers should be submitted for approval before being used.

"39. Trolley Wires:—

"(a) Must be no smaller than No. 0. B. & S. copper, or No. 4. B. & S. silicon bronze, and must readily stand the strain put upon them when in use.

"(b) Must be well insulated from their supports, and in case of the side or double-pole construction, the supports shall also be insulated from the poles immediately outside of the trolley wire.

"(c) Must be capable of being disconnected at the power house, or of being divided into sections, so that in case of fire on the railway route the current may be shut off from the particular section and not interfere with the work of the firemen. This rule also applies to feeders.

"(d) Must be safely protected against contact with all other conductors.

"40. Car Wiring:—

"Must be always run out of reach of the passengers, and must be insulated with a waterproof insulation.

"41. Lighting and Power from Railway Wires:—

"Must not be permitted, under any pretense, in the same circuit with trolley wires with a ground return, nor shall the same dynamo be used for both purposes, except in street railway cars, electric car houses and their power stations.

"42. Car Houses:—

"(a) Must have the trolley wires properly supported on insulating hangers.

"(b) Must have the trolley hangers placed at such a distance apart that in case of a break in the trolley wire, contact cannot be made with the floor.

"(c) Must have cut-out switch located at a proper place outside of the building, so that all trolley circuits in the building can be cut out at one point, and line circuit breakers must be installed, so that when this cut-out switch is open the trolley wire will be dead at all points within 100 feet of the building. The current must be cut out of the building whenever the same is not in use, or the road not in operation.

"(d) Must have all lamps and stationary motors installed in such a way that one main switch can control the whole of each installation (lighting or power), independently of main feeder switch. No portable incandescent lamps or twin wire allowed, except that portable incandescent lamps may be used in the pits; connections to be made by two approved rubber-covered flexible wires, properly protected against mechanical injury; the circuit to be controlled by a switch placed outside of the pit.

"(e) Must have all wiring and apparatus installed in accordance with rules under Class B.

"(f) Must not have any system of feeder distribution centering in the building.

"(g) Must have the rails bonded at each joint with not less than No. 2 B. & S. annealed copper wire; also a supplementary wire to be run for each track.

"(h) Must not have cars left with trolley in electrical connection with the trolley wire.

"43. Ground Return Wires:—

"Where ground return is used it must be so arranged that no difference of potential will exist greater than five volts to fifty feet, or fifty volts to the mile between any two points in the earth or pipes therein."

At the meeting of the National Conference a number of topics were suggested that might advantageously be incorporated into the new rules. Some of these are here presented for the consideration of street railway interests merely as an indication of general lines upon which there may be necessity for revision, and with the hope that they may evoke a very general expression of opinion from all concerned: Increased protection of lighting circuits; method of grounding generators; double insulation for trolley wires with iron pole construction; car wiring in moulding and interior conduit; automatic magnetic circuit breakers for cars; electric brakes; electric car heaters; use of lights from railway circuits in buildings operated by street railway companies, such as amusement pavilions, repair shops, waiting rooms, etc.; rail bonding; arc lamps on railway circuits.

It has been suggested that the new rules should cover very fully the subjects of car wiring and outside construction. They should deal not only with the construction objectionable from the standpoint of fire hazard, but also with respect to personal danger.

All suggestions should be forwarded at an early date, in order to secure full discussion, as the committee has but a limited time in which to consider and report upon recommendations to the Conference. FRANK R. FORD,
203 Broadway, N. Y.

March 24, 1896.

DR. PUPIN ON THE EDISON FLUOROSCOPES.

Messrs. Aylsworth & Jackson, of East Orange, N. J., presented me, on behalf of Mr. Thomas Alva Edison, with a tungstate of calcium fluoroscope. It is a magnificent piece of apparatus, and will undoubtedly prove of the greatest service in the new field of work opened up by Röntgen's discovery. I cannot speak too highly of its merits, and I take much pleasure in recommending it to all who are interested in Röntgen radiance. I wish to state also that this recommendation is spontaneous, and not in any way suggested or even hinted at by the generous donors.

Mr. Edison and his assistants—Messrs. Aylsworth & Jackson—deserve the deepest gratitude on the part of scientific men and the public at large for their magnificent fluorescent screens. M. I. PUPIN.

Faculty of Pure Science, Columbia University, New York.

AN INVALUABLE NECESSITY.

I enclose herewith my check for $3 for one year's subscription to "The Electrical Engineer." I beg to say that your valuable paper has become a necessity to me, and I consider the information I glean from its columns invaluable to me.

I must congratulate you on the exceedingly interesting articles which have appeared of late. I must especially commend you on the issuing of the "Data Sheets" and the information contained therein, and I consider that "The Electrical Engineer" stands pre-eminently at the head of the engineering journals.

Your recent issues relating to central stations have been very interesting.

Trusting you will keep on with the good work, I remain, yours very truly. PAUL H. BRANGS,
Electrical and Gas Engineer.

Hoboken, N. J., March 18, 1896.

MR. B. J. WOOD, of Babylon, L. I., has been appointed superintendent of the lighting plant of the Manhattan Beach Improvement Company, Coney Island.

CONTENTS.

ROENTGEN RAY EXPERIMENTS.

WHILE the interest, amounting almost to excitement, created among the general public by the discovery of Prof. Röntgen has almost subsided, such, we are glad to say, is not the case among scientists and inventors, who have at their disposal apparatus for carrying on experimental work of this nature. This is evident on glancing at the continuing contributions on the subject appearing in our columns. Indeed, the further study is pushed in this direction, the more it becomes certain that the Röntgen ray phenomenon will require the most careful investigation before its true character can be established. Already experiments seem to cast a doubt on the original belief as to the source of these rays, eminent experimenters, like Prof. Rowland and Prof. Elihu Thomson throwing the weight of their opinion in favor of the anode. Dr. Morton, with a very characteristic photograph, has shown that in his particular experiment the source of the X-rays was confined to a limited point of fluorescent material within the tube between the anode and cathode. It will be remembered that Prof. Röntgen, in his original essay, pointed out that the chief seat of the rays was located at the most brilliant phosphorescent spots on the walls of the tube, and was to that extent independent of either cathode or anode. For those who have not followed the history of the Röntgen ray we can strongly recommend the perusal of Mr. Osterberg's admirable résumé of the subject embodied in his lecture before the New York Electrical Society. We agree fully with Mr. Osterberg in recommending to all at work on, or about to undertake Röntgen ray experiments, to read carefully Prof. Röntgen's essay, which appeared in our issue of Feb. 12. As a collateral branch of investigation, much interest has been concentrated in fluorescent bodies, and investigators will, we ascertain, be grateful to Mr. Edison for having called attention to the tungstate of calcium, a material far more powerful than what had heretofore been commonly used.

In line with Röntgen ray experiments is the alleged discovery of a means for rendering transparent opaque objects placed in a certain position with regard to a number of chemical solutions. The description of this new development, as far as the inventor has permitted its publication, is given on another page. While, of course, we can not guarantee the authenticity of the story, we have given it on the testimony of reliable witnesses, and present it to our readers for what it is worth.

THE BOARD OF FIVE.

THE more the recent alliance between the General Electric and Westinghouse companies is discussed, the more it becomes apparent that a nearer union than that of mere patent licensing is probable. The proposed Board of Five is apparently a power that rises superior to either individual company, in that it constitutes a joint executive committee of both. Such a committee under any normal state of affairs would have pretty continuous occupation, even on the skeleton lines indicated in the formal announcement. But there is reason to believe that prices not less than patents are in the minds of the devisers of the alliance. Unless we are misinformed, it is an old plan of Mr. Twombly's to have a Board of Five to control matters generally. This board was not only to control prices, but all important contracts were to be submitted to it. That this should gradually appear to be the

real intention now under the new regime will not be surprising.

The task before the "Big Five" is herculean. Stated in a few words, it is nothing less than undertaking to earn dividends on a capital of $60,000,000, or more, in a field where competition is already active and is likely to become rifer. We discussed last week the various appliances that are free in the field of electricity, and while almost everything was enumerated, we have still to learn that our views are erroneous. Prices cannot, therefore, be cut, if dividends are to be paid on $60,000,000. If prices are maintained at the point where the "combine" can make an average profit of twenty per cent. on everything it sells, it must do an annual business of $25,000,000 in order to pay eight per cent. on its $60,000,000. At the same time, if there is $25,000,000 of business going at a margin of twenty per cent. profit, we think the alert, intelligent, industrious and specially informed manufacturer, on an independent basis, and devoting his whole energies to one or two lines is likely to get a large share of that trade.

It seems to us that this period is peculiarly favorable to the independent manufacturers. To begin with, the public sympathy and that of the whole electrical trade, is with them. Nobody likes to be compelled, under duress, to deal with one man or one concern. That is sheer industrial slavery, unless based on the merit of the goods, so that if one could, one would not go elsewhere to effect a purchase. Not only is the law against combines in restraint of trade, but public opinion and public action go further than the law. Moreover, the protean, plastic nature of electricity itself, is all the time making for greater conditions of freedom, and each achievement in the field, so far from tying up the art, simply promises a dozen new conquests. The manufacturer to-day who has a good thing, who pushes it boldly and who advertises it freely, will suffer from no want of general support. Parsimony and lack of courage are the things he has chiefly to fear, for if the field is let alone the "combine" will get the business, no matter what the quality of its goods might be.

THE INCANDESCENT FILAMENT AND THE WELSBACH AND ACETYLENE FLAMES HYGIENICALLY COMPARED.

DR. W. H. BIRCHMORE'S contributions on hydro-carbon flames, which have recently appeared in these columns, afford much material for those who are interested in defending incandescent lighting by electricity against the assaults of the gas interests. Taken in connection with his paper on the Bunsen burner spectrum, they cannot but remind our readers of what has been so often said about the danger to the eyes from the actinic rays given off by the intensely heated carbon gases of the regenerative burners and the Welsbach light. The peculiarly dangerous character of this last from the great volume and degree of its chemical radiation has been stated before, but the reason has never, so far as we are aware, been made quite so apparent. If this series of contributions is read consecutively, the following deductions are obvious, and should be forcibly stated by every one who is interested in the business of electric lighting:

1. These investigations show conclusively that the radiation from incandescent gases is dangerously rich in chemically efficient rays. Considered in relation to the eyes, therefore, the light from any solid heated by, and surrounded with, an envelope of incandescent gas, is hygienically bad and dangerous to the eyes. 2. The incandescent carbon of the ordinary gas flame, simply because it retains the flame at a lower temperature, and thus keeps down the radiation of the actinic influence given off by high temperature gases, is a useful check, while with the Welsbach mantle and other appliances of the same sort, there is no limit to the temperature possible, and no check exists in the nature of the case itself. 3. The incandescent filament, while rich in chemically efficient rays too rich for choice, contains less than a twelfth of the chemical rays in an oil flame of the same "visible radiation value," and not two per cent. of the amount given off by a Welsbach of the same nominal candle power. 4. There is a difference, not of degree only, but of kind, in the chemically efficient rays coming from the Welsbach and the filament, which will some day be better understood. 5. There is also an especial reason why the light from the acetylene flame is bad for the eyes. Not only is it of remarkable actinic power, but it is rich in the fourth sort of chemical rays—a kind which not only decomposes the yellow pigment of the eyes with a startling rapidity, but which prevents its formation to such an extent that the eyes are disabled from correctly appreciating colors by daylight after a prolonged use of the light of this flame.

There is no sort of doubt that if these facts are presented by those having electric light interests in charge to the attention of an intelligent public the use of the filament as a source of light must increase rather than diminish in the competition with the new and "improved" means of illumination by gas.

THE COMING EXPOSITION.

THE preliminary list of exhibitors given out this week by the officers of the National Electrical Exposition, soon to be supplemented, we are informed, by another list of large proportions, is enough in itself to indicate that the affair will be the success we all desire. The exhibits will evidently be large, varied and comprehensive, and, together with the many special features that are to be added by the management itself, will do more to educate the public in the general use and appreciation of electricity than anything else that has been done these ten years past. It will be noted that in the departments of steam power and current generation, the list is remarkably strong, and this is in itself very satisfactory, for the average citizen has still much to learn in that respect. When he sees how simple the mechanism and modus operandi is, he will be the quicker to inquire why he is still debarred from the service of this modern agency in his home and business for the larger uses of comfort and convenience.

Other features of the Expositon are not less hopeful, as, for example, Mr. Edison's generous intention, not only to contribute largely to the historical and loan exhibit, but to place freely at disposal several sets of fluoroscopes and Röntgen ray apparatus, so that everybody can see the whole thing and try the new process of internal inspection for himself. In fact, now that the management has been so successful in disposing of its space, and thus in providing very properly for financial success, it may well give as much attention as possible to the educational side of the great show. That in turn will prove remunerative, not alone immediately to it, but in the long run to every exhibitor.

ELECTRIC LIGHTING.

FURTHER EXPERIMENTS IN FLUORESCENCE UNDER THE CATHODE RAY.

BY

Thomas A. Edison.

FURTHER experiments with the fluorescence of different chemicals under the influence of the X-ray have added a few more to the list already published. The following fluoresce: Cadium tungstate, tungstate of zinc, lithia benzoate, tannate lead, carbonate lead, salicylate potassium, carbonate silver, sodium salicylate, sodium carbonate, sodium tungstate, zinc acetate, zinc chloride, zinc carbonate, molybdate zinc, benzoic acid, malic acid, diphenylamine, ruffigallic acid, pyridin nitrate.

I have so far found no salt in the following metals to fluoresce: Aluminum, antimony, arsenic, boron, beryllium, bismuth, cerium, chromium, cobalt, copper, gold, iridium, magnesium, manganese, nickel, tin, titanium.

The crystals of the following chemicals give spots of light when held close to the bulb within a dark box. The light has the glowworm color of phosphorescence, and is due to the electric discharge and not to the X-ray: Ammonium, sulphocyanide, calcium formate, calcium nitrate, iron citrate, silver nitrate, soda, lime, zinc, cyanide, zinc hypermanganate, zinc valeriate.

THE EDISON FLUOROSCOPE IN USE.

With plates of fluorite I have found that the phosphorescence penetrates the plate very slowly. If held before a fluorescing tube for one minute, the phosphorescence penetrates for 1-16 of an inch deep in the plate. This part, when held edgewise, is brilliant; beyond is dark.

(The latest form of fluoroscope designed by Mr. Edison is that illustrated in the accompanying engraving. It consists of a flaring box, curved at one end to fit over the forehead and eyes, like a stereoscope. The end of the box is closed by a pasteboard cover, on the inside of which is spread a layer of tungstate of calcium, which material Mr. Edison reports he has found to possess six times the fluorescing power under the influence of the X-rays, as compared with barium platino-cyanide.

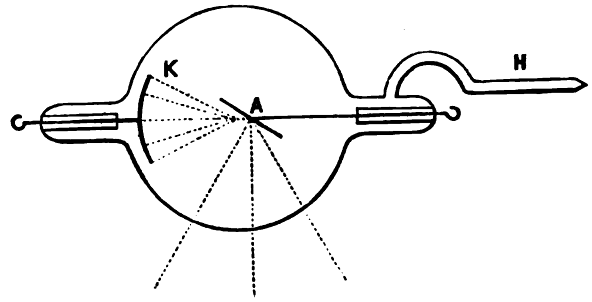
By placing the object to be observed, such as the hand, between the vacuum tube and the fluorescent screen, the shadow is formed on the latter and can be observed at leisure. In order to exclude all light from the screen, the curved part of the fluoroscope encircling the eyes is lined with black ostrich feathers, so that the experiments can be carried on in broad daylight, if desired.

These fluoroscopes are manufactured by Messrs. Aylsworth & Jackson, of Orange, N. J., who have very kindly placed one of them at our disposal for illustration. EDS. E. E.

A NEW X-RAY "FOCUS" TUBE.

A NEW tube for producing the X-rays has recently been designed by one of the professors at King's College, London, which, according to the London "Electrical Review," is so great an improvement on anything in this line that has been previously produced, that it will undoubtedly give a great impulse to the practical applications, especially to surgery, of the new photography.

The cathode rays are focused to a point where they impinge on a plate of platinum fixed on the anode. The X-rays radiate from this point, and, of course, produce a much sharper shadow of the object being photographed than when radiating from the extended luminous patch on the glass of the tube which has hitherto generally been used. Fig. 1 shows a section of the "focus" tube. The cathode plate, K, is a concave disc of aluminum which focuses the cathode rays at a point near the center of the bulb. The anode plate, A, is a small



NEW RONTGEN RAY FOCUS TUBE.

piece of platinum foil placed at an angle a short distance beyond the focus of the cathode rays. Curiously enough, the cathode rays do not cross like rays of light at the focal point, but behave rather like a number of fluid jets coalescing at the focal point, and proceeding thence onwards as a solid parallel jet. The point where the rays impinge on the platinum still retains its small dimensions, though the plate is placed some distance beyond the focal point.

Platinum is known to be one of the most opaque substances for the cathode rays, and thus very little of the radiation passes through the platinum foil. The greatest part of the radiation is absorbed by the platinum, and given out as X-rays from the luminous point by a kind of diffuse reflection. The anode plate, A, being set at an angle, the best part of the radiation is directed downwards through the sides of the bulb, where it can be conveniently utilized to produce the photograph in the usual way. The tube, H, through which the bulb is exhausted, is shaped so as to permit the tube to be fixed in a stand at the required height. The anode and cathode plates are connected to the terminals of the induction coil by platinum wires fused through the glass.

ROENTGEN RAY LITERATURE.

THE "Comptes Rendus" for February 17 contains, as usual, numerous communications on the subject of Röntgen rays. M. R. Swyngedauw has a communication on the subject of the lowering of the sparking distance. MM. L. Benoist and D. Hurmuzescu present a paper in which they state that they have verified that Röntgen rays are propagated in air according to the law of inverse squares. They also state that the Röntgen rays are heterogeneous. They base this statement on the fact that they find the coefficient of transmission for a 0.1 mm. thickness of aluminum to be about 0.85, and they go on to say that such a value is absolutely incompatible with the very sensible transparency that Professor Röntgen observed for a plate of aluminum 15 mm. thick, if we assume that the coefficient is independent of the Crookes tube employed, and if it does not increase with the thickness traversed—that is to say, if X-rays are not subjected when passing through aluminum to selective absorption, which is a proof of heterogeneity. If the value 0.85 were constant the total transparency of a

sheet 15 mm. thick would be represented by 26×10^{-12}. MM. Benoist and Hurmuzescu then carried on experiments with increasing thicknesses. They found that the coefficient increased from 0.85 for sheets not exceeding 0.6 mm. thick, to 0.9 for sheets exceeding 1 mm. They next employed different Crookes tubes under identical conditions, and found that the coefficient of transmission varied from 0.85 to 0.78. Another communication was made by MM. Auguste and Louis Lumière describing some experiments carried out by them with a view of ascertaining the amount of absorption which Röntgen rays undergo when passing through sensitive films. After ten minutes' exposure they found that photographic effects were produced through a packet of 250 sheets of gelatino-bromide-silver paper; they further found that 300 sheets of paper without the bromide emulsion exercised the same absorptive effect as 150 sheets of sensitized paper. They then experimented with photographic plates having different degrees of sensitiveness for white light in the ratio of extent of 1.8 to 30, and they found that within the limits of their experiments this ratio was exactly the same for Röntgen rays.

OPAQUE OBJECTS MADE TRANSPARENT BY RAYS PASSING THROUGH CHEMICAL SOLUTIONS.

We have received from a correspondent at Parkersburg, W. Va., an account of an alleged remarkable discovery which, if verified, places it well on a par with the now famous discovery of Professor Röntgen. The discovery referred to is due to Mr. A. G. Davis, of Parkersburg, and consists in an arrangement of chemical solutions, the effect of which is to make opaque bodies transparent to light.

The discovery is said to have come about in this way: Mr. Davis, who is a jeweler by trade, was engaged in soldering, seated at a table with three bottles of chemicals before him. In one hand he held a fourth bottle and in the other a file. By accident, he held the file between the bottle in his hand and the three bottles on the table, and, much to his surprise, only the ends of the file were visible. A number of other objects, including the hand, were tried, all appearing transparent. The accompanying engraving, Fig. 1, shows the first apparatus constructed by Mr. Davis, consisting of two end boxes containing the bottles of chemical solutions, with what is said to be a solid block of steel 12 x 18 x 25 inches between them. The internal arrangement of the end boxes is shown in Fig. 2, which exhibits their contents exposed. Both these boxes in their latest form have glass fronts and backs. The box on the left hand is the one containing the single chemical and which is the one placed next to the observer. The bottle has two wires connected to it which extend to a metal plate inside of the small box shown above the bottle. A crank is so arranged that by turning it the contents of the bottle are shaken, and this agitation is said to produce the effect of making the metal plate inside the small box transparent.

The box farthest from the observer is shown at the right in Fig. 2. This also contains a small auxiliary box, tightly

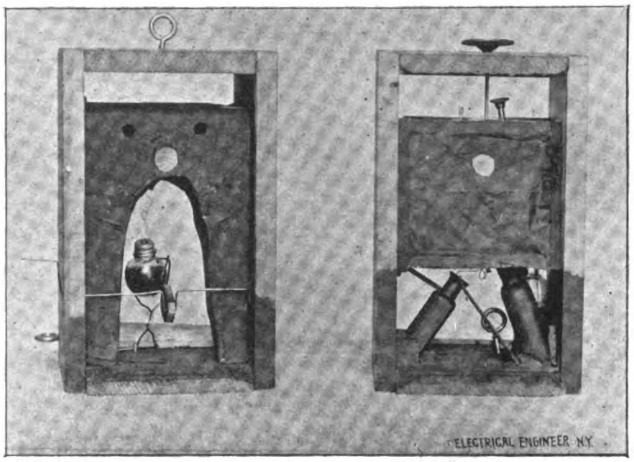


Fig. 2. The Boxes Exposed.

closed, with a one-inch aperture and piece of tinfoil back of it and a piece of windowglass over it. This small auxiliary box also contains a metal placed behind the aperture, and from the plate wires extend to the bottles shown. In order to avoid the suspicion that the results may be due to an arrangement of concealed mirrors, placed in the board supporting the two boxes and block of steel, in the latest arrangement the two boxes are entirely independent of each other. In a communication received from Mr. Davis himself, that gentleman writes: "I have found by a combination of four chemicals that I can make transparent any opaque object, one being on one side of the opaque object and the other three on the other side. I have further made a second and later discovery, that the powers of the chemicals can be transmitted by means of small wires to a metal plate, which, if enclosed in a dark box, makes a sort of fluorescent screen, and by looking through it all opaque objects become transparent the same as if looking through the one bottle of chemicals.

"I will not reveal the name or nature of the chemicals, nor

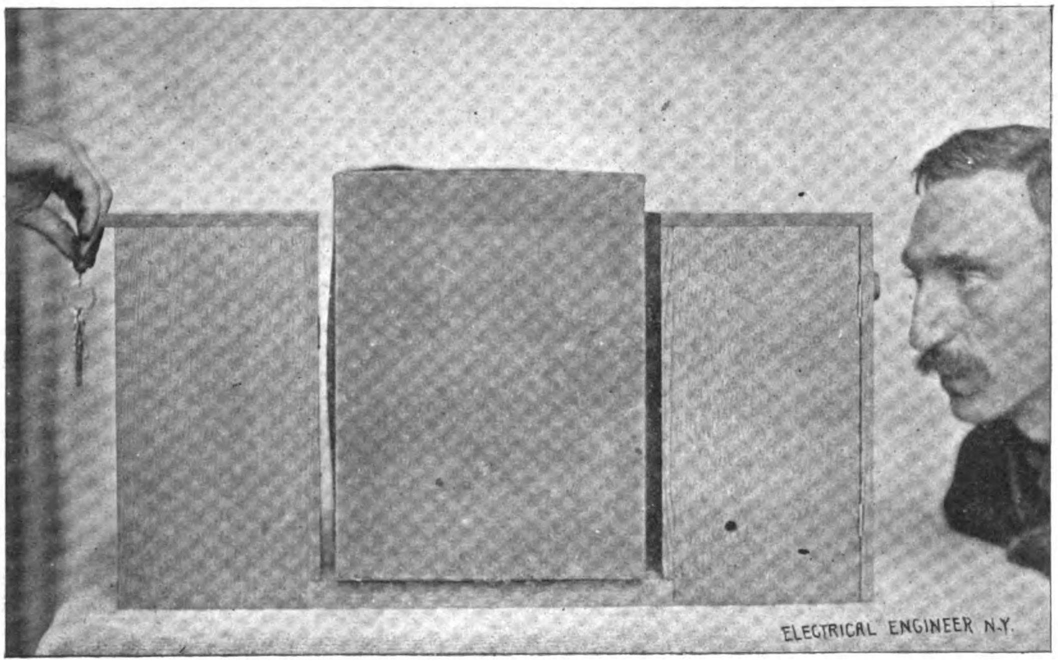

Fig. 1. Davis's Method of Viewing Objects Through Opaque Bodies, by the Aid of Chemical Solutions.

Photograph by Emil Korb, of Parkersburg, W. Va.

the metal plates, but hundreds here in this city have seen their results. In order to conceal their identity, I enclosed them in two closed boxes on the two ends of a board in order to keep them in darkness, as I find that the sunlight had a weakening effect on their powers.

"The later metal discovery enabled me to allow the chemicals to remain in the light, but I must keep the metal in the dark box, as shown in the engravings."

THE PIONEER INCLOSED ARC LIGHT FOR INCANDESCENT CIRCUITS.

OUR readers will recall that at the National Electrical Congress held in Chicago in 1893, Mr. L. B. Marks, the well-known carbon and arc light expert, read a paper on the inclosed arc light. The paper made considerable of a sensation, and while, even at that time, the results obtained were

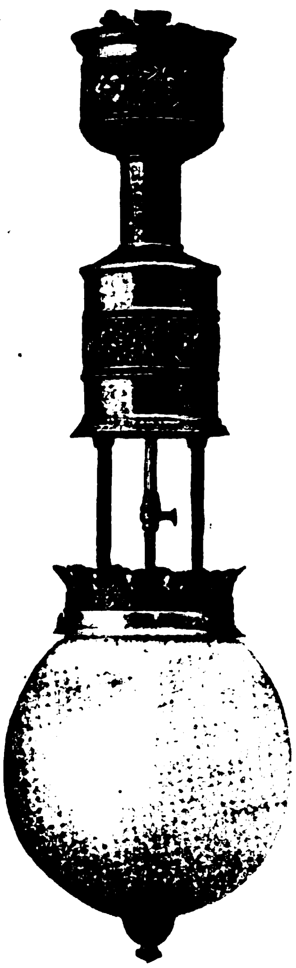

FIG. 1.
THE PIONEER STANDARD INDOOR LAMP.

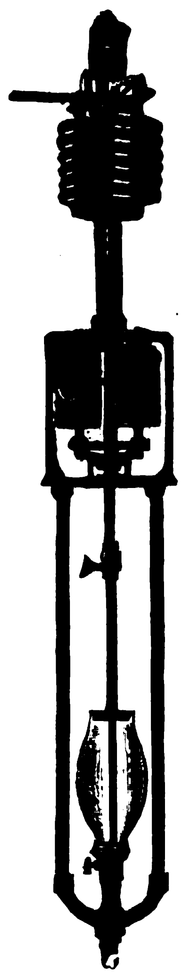

FIG. 2.
PIONEER LAMP WITH CASE AND GLOBE REMOVED.

remarkable in their way, the improvements which have since been effected by Mr. Marks are such that the inclosed arc lamp now occupies a position of established reputation in the field of illumination. That this statement is fully warranted must be conceded when we state that nearly one thousand of the "Pioneer" inclosed arc lamps, as the Marks lamp is called, will be installed in the great New York department store of the Siegel-Cooper Company, now rapidly nearing completion. The selection of the Pioneer inclosed arc lamp was by no means a matter of chance, but was decided upon after a competitive test with nearly every other arc lamp in the market.

The improvements which have been effected will be apparent by a glance at the accompanying illustrations. In these, Fig. 1 shows an outside view of the Pioneer standard indoor lamp, while Figs. 2 and 3 show the interior with the case removed, and also an enlarged detail of the mechanism; the latter, it will be noted, is extremely simple in character, consisting merely of a pair of solenoid magnets bearing the clutch mechanism; no springs or auxiliary mechanism of any kind being employed.

The features which make the Pioneer arc lamp particularly valuable are: First, that the lamps require trimming at intervals of only ten days, or two weeks, while in some situations with short hours of burning a monthly trimming only would be necessary. The lamp does not require cored carbons, the ordinary solid carbons being used. This results not only in a saving on the cost of carbons, but also in that of trimming—items which, together, aggregate a saving of from fifteen to twenty dollars per year per lamp.

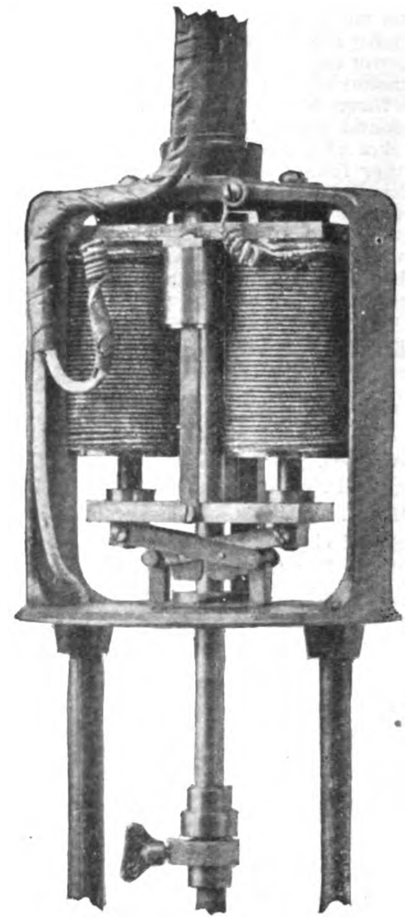

FIG. 3.—THE PIONEER LAMP MECHANISM.

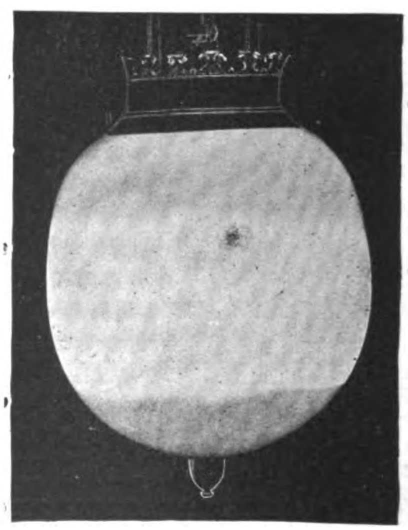

FIG. 4.—SHADOWS ON GLOBE OF OLD STYLE LAMP.

Owing to the arc being inclosed, it is possible to run the lamp on incandescent circuits at a much higher potential than

where the arc is not inclosed, so that the Pioneer lamp can be run singly, each lamp independent of the other. It follows from this also that one lamp cannot rob the other of light, as is frequently the case where two are run in series. As regards distribution of light, which is an essential factor, both in outdoor and indoor lighting, the inclosed arc has a decided advantage over the open air arc. This is well illustrated in Figs. 4 and 5. Thus, Fig. 4 is a direct reproduction from a

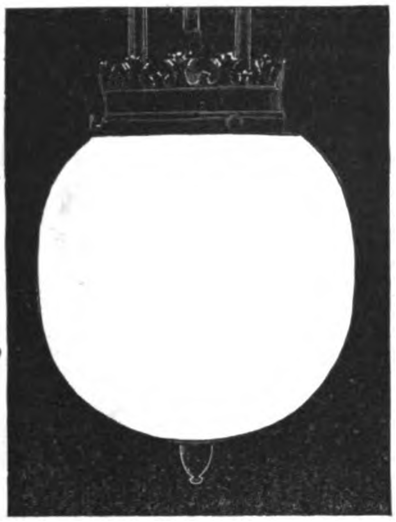

FIG. 5.—SHADOWLESS GLOBE OF THE PIONEER LAMP.

photograph of an open air arc lamp, showing the shadows cast by the carbons, while Fig. 5 is a photograph of the Pioneer inclosed arc lamp, showing a remarkably even distribution of light. This quality of the lamp will be especially appreciated by storekeepers and factory owners, as it avoids one of the greatest inconveniences attached to the old form of arc lamp.

Not the least important advantage of the inclosed arc is its perfect cleanliness, since all the carbon dust is completely consumed, and, above all, its perfect qualities as a spark arrester. This has an important bearing on the insurance question, and the lamp on this account has been thoroughly indorsed by the fire underwriters.

The Electric Arc Light Co., manufacturers of the Pioneer arc lamp, have secured a fine suite of offices and salesrooms at 687-689 Broadway, and agencies are being established in every important city in the Union.

NOTES ON CONCENTRIC WIRING.

BY C. J. KINTNER.

I HAVE read with very much interest the paper of Mr. Sam Mavor on "Concentric Wiring," published in the January issues of "The Electrical Engineer" and referred to in numerous other electrical journals at various times since its publication. To the question of concentric wiring, I gave much attention, as early as 1886, when the induction system of electric lighting of Gaulard & Gibbs was introduced into this country by Mr. Westinghouse, it being obvious to me at that time that with a high tension system of primary currents, a protective system of wiring would be necessary. I have written a number of articles touching, and taken a number of patents covering broadly, the principle of concentric wiring wherein the inner conductor is removable from the outer or concentric conductor, and have made various improvements in concentric safety or protective devices for use in connection therewith.

Although Mr. Mavor has pointed out very clearly many of the advantages of the concentric system over existing systems of wiring, and also the fact that such a system is much safer than is possible with a two-wire system, there are other important advantages which he has failed to note and to which I desire to direct attention if you will grant me the space in your valuable paper at this time.

First, he has failed to note that oftentimes with existing systems of wiring in which lead cables are used, the cables are ruptured; and no one, so far as I know, has yet satisfactorily explained the reason of such rupture. It is undoubtedly due to high statical charges upon the cables during thunderstorms, or, at times when atmospheric electricity is conveyed to said cables from the surface conductors, the high static charge undoubtedly penetrating the cables and therefore effectually ruining them.

Second, no one has yet, so far as I am aware, satisfactorily accounted for the explosions in manholes and subways where electric wires are found. Such explosions are undoubtedly due to the presence of electric wires, as they were, so far as I am aware, unknown or certainly of very rare occurrence before wires were placed in the subways. Although these explosions have been attributed to leaking gas from gas mains ignited by the presence of an arc from subway conductors, or to the generation of explosive gases through the electrolytic action of metals with which the cables are armored, I am convinced that most of these theories in this direction are absolutely incorrect, and that such explosions are really due to the presence of atmospherical electricity conveyed to the subways by the surface conductors, and I base my conviction in this direction upon the fact that all the subway explosions I have ever heard of have occurred in the summer time, or at that period of the year when atmospheric electricity is prevalent. If any one of the readers of this article is aware of any such explosion at a time other than during the season when exterior or atmospheric currents are liable to find their way to the subways, I should be pleased to hear of it.

It is also a matter of common knowledge that persons often receive marked shocks from incandescent globes connected with existing systems of electric lighting; such shocks, I may add, as are not possibly attributable to currents of the voltage used at the lamps. They can therefore only be attributable to atmospheric charges which do not find their way to earth through the absolutely perfectly insulated systems of lighting as now used in this country. With a perfect system of concentric wiring having absolutely earthed contact at all points for the outer conductor, no safer system of lighting or transmission of power can possibly be imagined, so that all of the bugaboo raised by the insurance companies and those who oppose the earthing of the third wire in the Edison system is in in fact fallacious, provided, of course, that such third wire be inclosed in a concentric conductor, which is properly earthed.

The English people are far in advance of us in the matter of the use of concentric wiring, and Mr. Mavor in his able article, so clearly points out how perfectly such a system works, even with the poorest kind of insulation, that it seems to me engineers in this country are standing in their own light in not freely acknowledging the advisability of the use of this type of conductors.

A NEW METHOD OF STUDYING THE LIGHT OF ALTERNATING ARC LAMPS.[1]

BY W. L. PUFFER.

THE author first referred to the general characteristics of the continuous current arc. To demonstrate the properties of the arc the latter was thrown on a screen and observed by the stroboscopic method by means of a revolving disc, with slots cut in it, and revolved so as to intercept the rays from the arc at definite periods.

The experiments clearly show that the alternating current arc is a sequence of direct current arcs, alternating in polarity, and that each wave of current produces very clearly and distinctly all the attributes of the direct current arc.

In subsequent experiments with a synchronous alternating motor, a disc was used having half as many slots as there were pole pieces on the dynamo. With 500 volts, and a large non-inductive resistance in series with the arc, it was plainly evident that the current wave was approximately sinusoidal, as the time of extinction of the current, as indicated by the blue band of the arc proper, was very short, and the rise and fall of the current gradual, and with no irregularities. This was to be expected, as the back e. m. f. of the arc is small compared to the voltage of the generator, and the circuit as a whole is non-inductive.

The opposite condition was realized by using a lower e. m. f. and regulating by a reactive coil. The time of no current was longer, and the current appeared to jump to its maximum in an exceedingly small angular time. In this case the arc was not steady, showing clearly to the eye that the succeeding waves of current were not alike either in form or current value, and also that the angle of lag was constantly changing. This fact has always prevented an accurate plotting of wave forms by the instantaneous contact method, and, although known to exist, was never before actually seen.

A very pretty double arc was arranged by using three carbons and wiring two circuits, each with current regulators, in such a way that the arc was the common junction, and one

[1]Abstract of a paper read before the American Institute of Electrical Engineers, March 25, 1896.

carbon was of one polarity, while the other two were of opposite polarity. With wire resistances in each side, there was nothing peculiar to be noted other than the effects of the junction of two currents, but when the resistance in one circuit was gradually cut out, and equivalent inductance cut in, there was at once visible evidence of the lag of the current, together with the change of shape of the wave and the unsteadiness before noted. Owing to the long time of no current in the inductive side there were times when even with considerable lag there were actually no visible traces of current between either points.

In this way there have been studied single arcs of high and low e. m. f., long and short double arcs, arcs with much inductance in circuit, Jablochkoff candles, arc between a ring and a point within, the spinning arc between the ends of a carbon cylinder and a concentric carbon within, with a magnetizing coil around the inner carbon and the like.

One of the most beautiful arcs investigated visually and photographically was a rotary arc made by the use of three carbons in the same plane, at angles of 120° apart and wired up as the junction point of an external Y load on a 500-volt 60 cycle three-phase generator. Non-inductive resistance was used in the circuit, and the current used in one leg of the Y was 10 or 15 amperes.

The three-phase arc is less noisy than the single phase, and its light is steadier and has less variation in its total intensity, owing to the fact that the current never stops, and there is always a positive carbon. Three cored carbons, placed parallel side by side, with slight magnetizing coils to keep the arc at the ends of the carbon, will give a very satisfactory light in the direction away from the tips, and may be used when it is desirable to throw the light all in one direction.

Four carbons at 90° apart, each with a suitable resistance in series with it, and connected to quarter-phase tap wires on a Gramme ring or other generator giving quarter-phase circuits, will also produce a rotary field arc of great beauty and interest. Prof. Puffer is continuing these experiments.

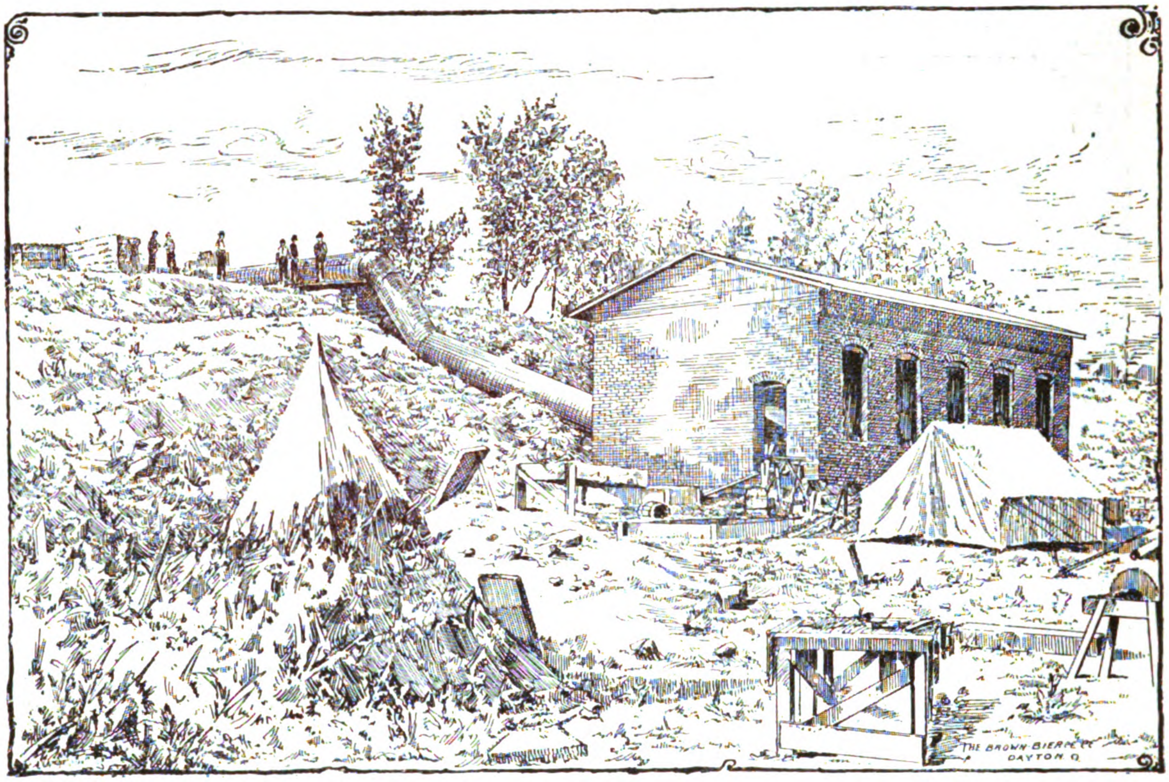
MUNICIPAL PLANT FOR RIVERSIDE, CAL.

Mr. Geo. A. Johnston informs us that the contract for the Riverside, Cal., municipal lighting plant is now being carried out by the California Electrical Works, of San Francisco, who furnish all the labor and material. This includes a 21-mile, 10,000-volt transmission line, as well as the city mains. For lighting, 100 Helios alternating arcs will be used. The transformers will all be of Helios make. The price is $40,978.

POWER TRANSMISSION.

A NOVEL IRRIGATING AND ELECTRIC PLANT AT MESA, ARIZONA.

THE cut herewith illustrates a special water power plant constructed by the Stilwell-Bierce & Smith-Vaile Company, Dayton, O., for the Consolidated Canal Company, Mesa, Ariz. The water is taken from the Salt River and carried by a 48-inch feed pipe across the Utah Canal to a pair of 21-inch cylinder gate Victor turbines on a horizontal shaft, developing 400 horse-power under 40 feet head. One end of the shaft is connected by a friction clutch to a 200-horse-power dynamo, which furnishes light and power for the town of Mesa, Ariz. The other end of the shaft is connected to a pumping plant for irrigating purposes. This novel station is suggestive of great possibilities in this line.



ELECTRICAL AND IRRIGATING PLANT IN ARIZONA.

THE WELLAND POWER & SUPPLY CANAL COMPANY LTD.

The Welland Power and Supply Canal Company, Limited, was incorporated under special act of the Dominion of Canada in 1894, for the purpose of utilizing the natural water supply of the Niagara and Welland Rivers, with the object of promoting manufacturing industries and inducing the establishment of manufactories and the development of general business. The company now propose to construct and operate a canal and hydraulic raceway from a point in the Welland River, within five miles of its mouth, across comparatively level land, to a point or points on the Niagara escarpment, with such enlargements of the natural watercourses in the townships of Grantham and Niagara, as may be necessary for carrying off the water from the power canal to Lake Ontario.

URBAN & CO., the great milling firm of Buffalo, issue a very handsome calendar to their many friends. This year it contains some excellent views of the Niagara power enterprise. Mr. George Urban has long been interested in electric light and power work, and his flour mills are one of the sights of the "new Chicago."

MR. JOHN B. WHITE has succeeded Mr. J. A. Wallace as superintendent of the Eastchester (N. Y.) Electric Light Co.

SOCIETY AND CLUB NOTES.

PRELIMINARY LIST OF EXHIBITORS AT THE ELECTRICAL EXPOSITION.

WE publish below a preliminary list of exhibitors at the National Electrical Exposition to be held in this city next May, and Mr. G. F. Porter, the secretary, states that another list nearly as large is in hand of exhibitors, who have reserved space, but whose contracts have not yet been signed. This absorbs the 36,000 square feet of space contracted for, and the Exposition Company has already deemed it advisable to contract for another 10,000 square feet of space equally desirable. Details of many features of interest are promised for early publication. The partial list given below is strikingly representative:

LIST OF EXHIBITORS.

A. A. McCreary, New York.
Abendroth & Root Co., New York.
Adams-Bagnall Electric Co., Cleveland, O.
American Carbon Co., Noblesville, Ind.
American Stoker Co., Dayton, O.
Babcock & Wilcox Co., New York.
Ball & Wood Co., New York.
Bishop Gutta Percha Co., New York.
Birdsall Electric Manufacturing Co., New York City.
Bryant Electric Co., Bridgeport, Conn.
Brady, T. H., New Britain, Conn.
Bradford Belting Co., Cincinnati, O.
Bryan-Marsh Electric Co., New York.
Bossert, Wm. F., New York.
Burry, John, New York.
Card Electric Motor & Dynamo Co., Cincinnati, O.
Carpenter Enamel Rheostat Co., Hoboken, N. J.
Calculagraph Co., New York.
Clark Electric Co., New York.
Columbia Incandescent Lamp Co., St. Louis, Mo.
Corey, R. B., New York.
Chapin-Douglass Electric Co., New York.
Cutter Electrical Manufacturing Co., Philadelphia, Pa.
Crocker-Wheeler Electric Co., New York.
Columbia Rubber Works Co., New York.
Crouse-Tremaine Carbon Co., Fostoria, O.
Crane Co., New York.
Diehl Manufacturing Co., Elizabethport, N. J.
Dale, Farrell & Co., New York.
Eddy Electric Manufacturing Co., Windsor, Conn.
Edison Electric Illuminating Co., New York.
Electric Storage Battery Co., Philadelphia, Pa.
"Electrical Engineer," New York.
Electricity Newspaper Co., New York.
Forest City Electric Co., Cleveland, O.
Ferracute Machine Co., Bridgeton, N. J.
Fuel Economizer Co., Matteawan, N. Y.
Goubert Manufacturing Co., New York.
General Electric Co., Schenectady, N. Y.
Gordon-Burnham Battery Co., New York.
General Incandescent Arc Light Co., New York.
Harrisburg Foundry and Machine Co., Harrisburg, Pa.
Huebel & Manger, Brooklyn, N. Y.
Holtzer-Cabot Electric Co., Boston, Mass.
Heine Safety Boiler Co., St. Louis, Mo.
Hunt, C. W., Co., New York.
Ironclad Rheostat Co., Westfield, N. J.
India Rubber and Gutta Percha Insulating Co., Yonkers, N. Y.
Jewell Belting Co., Hartford, Conn.
Johnston, W. J., Co., New York.
Keasbey, R. A., New York.
Kennedy Valve Co., New York.
Keuffel & Esser Co., New York.
Lozier, R. T., New York.
Locke Regulator Co., New York.
L. Katzenstein, New York.
Mica Insulator Co., New York.
McEwen, J. J., Manufacturing Co., Ridgeway, Pa.
National Carbon Co., Cleveland, O.
National Conduit Manufacturing Co., New York.
New York & Ohio Co., Warren, O.
Nowotney Electric Co., Cincinnati, O.
Nuttall, R. D., Co., Allegheny, Pa.
Niles Tool Works Co., Hamilton, O.
Okonite Co., New York.
Phoenix Iron Works, Meadville, Pa.
Peck Electrical Co., New York.
Partrick & Carter Co., Philadelphia, Pa.
Peru Electric Manufacturing Co., Peru, Ind.
Payne, B. W., & Sons, Elmira, N. Y.
Proctor-Raymond Co., Buffalo, N. Y.
Reisinger, Hugo, New York.
Riker Electric Motor Co., Brooklyn, N. Y.
Roebling's Sons, John A., Co., New York.
Russell & See, New York.
Stirling Co., Chicago, Ill.
Schieren, Chas. A., & Co., New York.
Siemens & Halske Electric Co. of America, Chicago, Ill.
Sunbeam Incandescent Lamp Co., Chicago, Ill.
Straight Line Engine Co., Syracuse, N. Y.
Standard Electrical Lamp and Novelty Co., New York.
Standard Paint Co., New York.
Standard Underground Cable Co., Pittsburg, Pa.
Shultz Belting Co., St. Louis, Mo.
Stanley Electrical Manufacturing Co., Pittsfield, Mass.
Safety Insulated Wire and Cable Co., New York.
Stanley & Patterson, New York.
Schoonmaker, A. V., New York.
Smeltzer & Co., Nurnberg, Bavaria.
Straight Line Engine Co., Syracuse, N. Y.
The E. T. Burrowes Co., Portland, Me.
Tucker Electrical Construction Co., New York.
United Electric Improvement Co., Philadelphia, Pa.
United States Mineral Wool Co., New York.
Vacuum Oil Co., New York.
Vetter, J. C., & Co., New York.
Walker Manufacturing Co., Cleveland, O.
Warren, A. K., & Co., New York.
Wagner Electrical Manufacturing Co., St. Louis, Mo.
Weston Engine Co., Painted Post, N. Y.
Weston Electrical Instrument Co., Newark, N. J.
Williamsport Wooden Pipe Co., Williamsport, Pa.
Worthington, Henry R., New York.
Wilkinson Manufacturing Co., Bridgeport, Pa.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—NOMINATIONS FOR OFFICES.

AT the monthly meeting of council held March 25, the returns of nominations were canvassed and the following council nominees were selected: For president, Louis Duncan, of Baltimore; for vice-presidents, Charles P. Steinmetz, of Schenectady, N. Y.; Harris J. Ryan, of Ithaca, N. Y., and W. M. Stine, of Chicago; for managers, J. W. Lieb, Jr., of New York City; F. A. Pickernell, of New York City; Wm. L. Puffer, of Boston,j and L. B. Stillwell, of Pittsburg; for treasurer, George A. Hamilton, of New York City; for secretary, Ralph W. Pope, of New York City.

The terms of the following officers do not expire this year: Vice-presidents Angus S. Hibbard, Dr. M. I. Pupin and W. F. C. Hasson; managers, A. E. Kennelly, C. S. Bradley, W. D. Weaver, W. B. Vansize, Charles F. Scott, Carl Hering, Cary T. Hutchinson and B. J. Arnold.

The rules have been amended by the council under advice of the Committee on Incorporation, in order to conform with the laws of the State of New York. The rules will hereafter be known as the "Constitution," and under its provisions the secretary is now elected by the Institute at large, instead of by the council. The system of cumulative voting is abolished. Copies of the revised constitution will be mailed to the membership with the ballots on or before April 15.

The following associate members were elected:

Philander Betts (3d), electrician, U. S. Navy Yard, Washington, D. C.; Charles Frederick Burgess, instructor in Electrical Engineering, University of Wisconsin, Madison, Wis.; A. Wright Chapman, electrical engineer, Fort Wayne Electrical Corporation, Baltimore, Md.; Wm. Edgar Firth, chief engineer, the Midvale Steel Co., Nicetown, Philadelphia; Frank R. Ford, M. E., consulting engineer, Ford & Bacon, 203 Broadway, New York City; Lucius T. Gibbs, manager and chief engineer, Gibbs Electric Co., Milwaukee, Wis.; Ch. Gorrissen, superintendent, Fort Wayne Electrical Corporation, Baltimore, Md.; Elwin Clinton Green, testing department and installing work, Jenney Electric Motor Co., Indianapolis, Ind.; Arthur A. Hamerschlag, electrical expert and owner, Hamerschlag & Co., 26 Liberty street, New York City; Wm. S. Hulse, electrical engineer, Fort Wayne Electrical Corporation, Baltimore, Md.; Arthur De La M. Lozier, M. E., salesman and expert, Westinghouse, Church, Kerr & Co., 26 Cortlandt street, New York City; Frederick Mackintosh, electrical engineer, General Electrical Co., residence, 9 South Church street, Schenectady, N. Y.; James W. Manson, wire chief, Franklin Street Exchange, Met. Tel. and Tel. Co.; Wm. J. Phelps, electrical engineer and contractor, Box 272, Asheville,

N. C., residence, Chicago, Ill.; H. Hobart Porter, Jr., agent, Westinghouse Electrical and Manufacturing Co., 120 Broadway, New York; Taylor William Ross, second assistant engineer, U.S. Revenue Cutter "McLane," Key West, Fla.; Howard R. Sargent, electrical engineer, General Electric Co., residence, 510 Union street, Schenectady, N. Y.; W. M. Stewart, wire chief, Met. Tel. & Tel. Co., 18 Cortlandt street, New York City; Howard F. Thurber, general superintendent, Met. Tel. & Tel. Co., 18 Cortlandt street, New York City.

At the meeting of the institute in the evening a paper was presented by Prof. W. L. Puffer, of Boston, on "A New Method of Studying the Light of Alternating Arcs." Sixty members and visitors were present. After the reading of the paper the meeting adjourned to Columbia University, where the experiments referred to were very effectively shown on a screen.

ELECTRICITY AS AN EXACT SCIENCE.

PROFESSOR FRANCIS B. CROCKER lectured before the Franklin Institute on March 20, on the above subject. The hackneyed expression that "electrical science is only in its infancy" was very vigorously denied by the lecturer. The remark recently published that "in a department of knowledge, whose principles are yet obscure, any moment may give birth to a fact revolutionary in its consequences," was regarded by Professor Crocker as a libel upon the profession of electrical engineering. A serious obstacle in the path of the electrical engineer is the general opinion that electrical science is a happy guesswork, and that its greatest engineers and inventors are peculiar geniuses or fortunate blunderers, who have stumbled on certain results without mental or other processes.

As a matter of fact, he said, electricity, as a science, is one of the most exact of the known sciences and second only to astronomy. The most important test of a science is the power of prediction. Upon that test astronomy stands pre-eminent, yet so exact is electrical science that the economy of the operation of a dynamo or motor can to-day be calculated from the drawings, before the machine is built, more nearly than by a test made of the machine itself. No one could assert the same of a steam engine or any other machine not extremely simple. In electrical engineering the uncertain quantities are mechanical ones, the friction of a belt, of a bearing, of the air resistance. But the calculation of the electro-motive force and current generated by the dynamo, the current consumed in the field, the Foucault currents in the armature and similar losses, are all the subject of exact mathematical calculation; the only doubtful elements would be mechanical.

The great names connected with electrical science are in themselves most powerful arguments in favor of its definiteness—Franklin, Faraday, Lord Kelvin, Maxwell and many of the most distinguished names that science has ever had, who were physicists before they were electricians. These names are not connected with indefiniteness of ideas; they are intellectual giants of the first magnitude. The rapid progress of electrical science is an argument in favor of its exactness. The entire development of electrical engineering has taken place within the last twenty years. In 1876 the telephone was first heard of; electric lighting came in 1878-9; electric metallurgy has received nearly all its development within that period. These permanent results would not have been possible with an inexact science.

The most surprising results to the popular mind are doubtless those attained in telephony, where conversation is carried on between Boston and Chicago. The transmission of 100 horse-power for a distance of more than 100 miles between Frankfort and Lauffen in 1891, with an efficiency of 75 per cent., has shown the world what can be done. The absolute calculations which are possible to the electrical engineer show that it is perfectly feasible to transmit power to even greater distances, and also to fix a limit to the economy of such transmission. The transmission of several messages over a single wire in opposite directions, or in the same direction and at the same time, is another of the great inventions of the brief period referred to. Yet these inventions were not stumbled upon, but were carefully worked out by the exact laws of electrical science. The construction of the great 5,000-horse-power dynamos which now utilize the power of Niagara was not a working in the dark. The great Corliss engine, the wonder of the Centennial Exposition of 1876, had but one-fifth the power of one of these dynamos, yet every part was accurately calculated. The first great machine was never tested until it was put in the place where it was to stand, and it was found to fulfill every expectation. No power machine of any nature of so great capacity was ever before constructed. It involved principles and constructive features that had never before been attempted, yet worked perfectly.

The fact which gives electrical science its exactness is the correctness with which electrical measurements can be made with the voltmeter and the ammeter. They are extremly accurate instruments, correct within 1 per cent.—can be used without stopping the machinery, and a test be made in a few seconds, which will determine the conditions of the circuit, and bring one face to face with the facts. No other power can be thus measured. The ability to test with such exactness is the foundation stone of the science.

THE FLUOROSCOPE AT THE NEW YORK ACADEMY OF SCIENCES.

THERE was quite a flutter among the ladies of the audience at the annual reception of the Academy of Sciences in the American Museum of Natural History on the evening of the 26th ult. Prof. Pupin gave a very interesting lecture, and, after pointing out the various steps leading up to Röntgen's discovery, and explaining the apparatus used in producing the X-rays, gave an exhibition of the capabilities of the fluoroscope. An uncanny atmosphere crept into the room as Prof. Pupin declared that he could see the skeleton of his own hand perfectly. After a while the audience took courage, and a number of them took advantage of the opportunity to look at their own phalanges, and were convinced. One woman feared she could not see the bones through her black glove, but she did see them and then hurried away. Prof. Pupin suggested that, instead of the "fluoroscope," the screen which has been made susceptible to the Röntgen radiance by a coating of the salt tungstate of calcium, should be called a "phosphoroscope," since the screen retains its luminosity some time after the passage of the X-rays has been cut off.

Although Prof. Pupin's lecture formed the most interesting feature of the evening reception, yet the many interesting exhibits of the latest development in science attracted much attention. In the electrical field the most noticeable exhibit was that of Prof. Pupin's apparatus for conducting X-ray experiments. In an alcove was shown in operation an instantaneous contact-maker attached to a 4-frequency alternator, driven by a small electric motor. A series of necessary measuring apparatus, including dynamometers, Kelvin multicellular voltmeter, transformers, etc., were all shown in circuit. Prof. Pupin also showed a motor transformer with current interrupter and a large number of interesting Röntgengraphs.

In addition to Prof. Pupin's exhibit, a very interesting series of Röntgengraphs were shown by various experimenters, notably one of a man's foot in his boot, taken by Nikola Tesla, showing in faint outlines the trousers, flesh, shape of the foot, and revealing distinctly the skeleton of the foot, the nails in the heel of the boot, and the eyelets and hooks for the laces.

A very interesting series of photographs of lightning were also shown, and a quantity of recent physical apparatus for electrical experiments.

N. E. L. A. TRANSPORTATION.

MR. C. O. BAKER, JR., Master of Transportation of the National Electric Light Association, reports as follows:

I am pleased to inform you that the Central Passenger Committee have granted the rate of a fare and one-third, on the certificate plan, from points in their territory to New York and return, for delegates attending the nineteenth convention of this association.

Mr. W. A. Kreidler, of the "Western Electrician," Chicago; Messrs. Bryan and Humphrey, Turner Building, St. Louis, and E. H. Heinrichs, of the Westinghouse Electric and Manufacturing Company, Pittsburg, will have charge of transportation matters in their respective localities.

A special party is being organized in Chicago, which will be joined en route by delegates along the line. A very large attendance is anticipated.

THE ASSOCIATION OF MISSOURI COMPANIES.

A special dispatch from Sedalia, Mo., of March 18, says: The Associated Water, Gas and Electric Light Companies of Missouri began their annual meeting here this afternoon, and will remain in session over to-morrow. In the absence of President W. E. Walton, of Butler, James A. Montgomery, of Sedalia, vice-president, called the meeting to order, and C. F. Strohm, of Nevada, officiated as secretary.

Considerable routine business was transacted, after which the following officers were elected for the ensuing year: Jas. A. Montgomery, Sedalia, president, R. D. Wirt, Independence, vice-president; C. F. Strohm, Nevada, secretary; Charles Carroll, Sedalia, treasurer.

The Executive Committee consists of the president, vice-president, and secretary, and F. J. Tygard, of Butler, and J. H. Shelton, of Clinton.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED MARCH 17, 1896.

Alarms and Signals:—

PNEUMATIC SIGNALING DEVICE. S. P. Hull and J. H. Boylett, Poughkeepsie, N. Y., 556,577. Filed Jan. 9, 1895.
Semaphore is operated by a piston controlled by electromagnets and means are provided whereby a pump is operated by passing trains to store the air.

BLOCK SIGNAL TELEGRAPH. C. M. Grace, Philadelphia, Pa., 556,070. Filed Sept. 10, 1895.
Is operated by a dynamo current proceeding from a single generator, each station being adapted to draw current from a common feed-wire and signal on either or both sides of a line wire.

Batteries:—

BATTERY CONNECTION. M. M. Kohn, Chicago, Ill., 556,544. Filed July 29, 1895.
The battery is mounted upon the same support or base board that carries the translating device.

SECONDARY VOLTAIC BATTERY. W. A. B. Buckland, London, England, 556,660. Filed July 15, 1895.
The active material is held in position on the plate without exposing any of the plate to the action of the electrolyte.

PORTABLE FARADIC BATTERY. J. E. Unger, New York, 556,708. Filed Feb. 6, 1896.
The exterior casing of the battery forms the electrodes and serves as an inclosure for a so-called "dry battery" and the induction coil.

Distribution:—

SYSTEM OF MULTIPHASE DISTRIBUTION. R. D. Mershon, Pittsburg, Pa., 556,359. Filed April 11, 1895.
For description see page 312, last issue.

Lamps and Appurtenances:—

ELECTRICAL CONNECTOR FOR ARC LIGHTS. J. J. McGill, Thorold, Canada, 556,362. Filed Jan. 15, 1896.
A ball and socket metal connection between the end of the loop wire leading to the lamp and the wire carried by the insulator leading from the line.

ELECTRIC ARC LAMP. G. C. Pyle, Indianapolis, Ind., 556,437. Filed May 2, 1895.
Designed especially for use in electric headlights.

ELECTRIC ARC LAMP. T. Spencer, Philadelphia, Pa., 556,479. Filed July 1, 1895.
Consists of a frictional feed regulator, a magnet controlling the same, and regulating the length of the arc and an independent stopping device for limiting the extent of slip of the friction mechanism.

ELECTRIC LAMP. C. E. Quimby, New York, 556,693. Filed Aug. 18, 1893.
A metallic shield incloses one-half of the lamp and extends through the central aperture of the lamp beyond the plane of the annular illuminating conductor, and a heat insulating backing is applied to the metallic shield.

Miscellaneous:—

ELECTRICAL GAS COCK. H. L. Taylor, Corning, N. Y., 556,386. Filed June 20, 1895.
The valve is operated by an electromagnet.

ELECTRIC HUB WELDING MACHINE. C. E. Hartman, Lynn, Mass., 556,414. Filed June 20, 1891.
Two work-electrodes adapted to squeeze or compress the work between them.

ELECTRICAL REGISTERING INSTRUMENT. H. Lemp, Lynn, Mass., 556,425. Filed March 12, 1891.
An actuating electromagnet having an iron core and coil related so that the iron of the core will saturate with a very small fraction of the maximum current employed in operating the register. Intended for welding machines.

ELECTRIC METAL WORKING APPARATUS. H. Lemp and W. B. Lewis, Lynn, Mass., 556,426. Filed April 23, 1891.
A single work holder forming a pole of the heating source is surrounded by a number of independently movable work holders, also connected with the source and provided with independent automatic cut-off devices.

ELECTRIC PROGRAM CLOCK. J. P. Luxmore, Chicago, Ill., 556,428. Filed Nov. 14, 1894.

ELECTRIC ELEVATOR. J. J. Parkinson, T. M. Martin and C. C. Bowen, Los Angeles, Cal., 556,435. Filed Feb. 7, 1895.
Details of construction.

ELECTRIC DRILL. M. Hebgen, Butte, Mont., 556,502. Filed July 16, 1895.
The armature is mounted on a hollow shaft through which extends the drill shaft, which is capable of longitudinal motion, that it may be fed forward to advance drill or be retracted.

ELECTRIC HEATER. J. E. Williamson, C. E. Collins and J. B. Graham, Allegheny, Pa., 556,524. Filed Feb. 9, 1894.
Details of construction.

ELECTRO-THERAPEUTIC APPARATUS. W. Carter, Louisville, Ky., 556,617. Filed Jan. 29, 1896.
Provides a motor generator capable of generating a direct and alternating current simultaneously.

ELECTRIC FURNACE. A. C. Girard and E. A. G. Street, Paris, France, 556,626. Filed May 24, 1895.
A heated chamber with electrode projecting into it, a passageway through chamber capable of receiving the object to be heated and means for producing a voltaic arc between said electrode and the object to be heated.

ELECTRIC FURNACE. A. C. Girard and E. A. G. Street, Paris, France, 556,626. Filed May 24, 1895.
A heated chamber with electrode projecting into it, a passageway through chamber capable of receiving the object to be heated and means for producing a voltaic arc between said electrode and the object to be heated.

DEVICE FOR DETECTING SHORT CIRCUITS. C. F. Scott, Pittsburg, Pa., and C. E. Skinner, Allegheny, Pa., 556,646. Filed Dec. 31, 1892.
Consists in varying the number of lines of force passing through a coil and determining whether or not said coil is heated thereby.

PROCESS OF EXTRACTING GOLD FROM SOLUTIONS. G. O. Pearce, Colorado City, Colo., 556,690. Filed May 8, 1895.
Consists in passing said solution through a mass of vegetable carbon having associated with it sulphate of iron, oxalic acid and tartaric acid.

ELECTRICAL APPARATUS FOR DRILLING WELLS, TUNNELS, ETC. P. Semmer, Irwin, Pa., 556,718. Filed Aug. 16, 1895.
Employs a motor contained within a casing, the drill being mounted on the lengthened armature shaft of said motor.

Railways and Appliances:—

MOTOR SUSPENSION. N. C. Bassett, Lynn, Mass., 556,488. Filed Nov. 27, 1895.
One end of motor is geared to axle and the other to a bar on yoke supported by the truck frame at substantially the plane of the center of gravity of the motor.

ELECTRIC RAILWAY SYSTEM. B. E. Osborn, Auburn, N. Y., 556,516. Filed Sept. 3, 1895.
Embodies a switching device for connecting the feeding conductor to the working conductors.

RAILROAD CROSSING SIGNAL. R. O'Toole, Thurmont, Md., 556,553. Filed Feb. 20, 1895.
So constructed that a signal will be given when the train is approaching the crossing, but not when it is passing away from the crossing.

UNDERGROUND CONDUCTOR FOR ELECTRIC RAILWAYS. G. Westinghouse, Jr., Pittsburg, Pa., 556,602. Filed Jan. 6, 1894.
Composed of two like halves fastened together by means of conducting devices and having adjacent contact faces separated by a clear space.

ELECTRIC LOCOMOTIVE. T. E. Adams, Cleveland, O., 556,654. Filed Sept. 5, 1894.
The motor is so suspended that the weight of the motor and parts carried thereby will be equally distributed at opposite sides of the suspending devices.

SAND-BOX FOR ELECTRIC OR OTHER CARS. C. H. Cox, Haverhill, Mass., 556,712. Filed Dec. 17, 1895.
A sand-box having an outlet, and means for closing it, a movable member of a chute and means for operating it, and an inclined end.

Switches, Cut-Outs, etc.

ELECTRIC MOTOR RHEOSTAT. T. J. Fay, New York, 556,342. Filed Dec. 12, 1895.
Adjacent to the rheostat frame and mounted eccentrically upon the same shaft is a series of contacting rings, suitably mounted upon a cylinder, and effectually insulated from each other by alternately disposed layers of mica.

RHEOSTAT. T. J. Fay, Brooklyn, N. Y., 556,408. Filed Dec. 10, 1895.
A controlling lever, an electromagnet, the lever being pivoted to one of the poles of the magnet, a spring arranged to swing the lever on its pivot, the magnet being included in two circuits adapted to oppositely magnetize its core.

ELECTRIC SWITCH. N. Marshall, Boston, Mass., 556,510. Filed Dec. 14, 1895.
Employs spring actuated pawls on locking devices, one of which is in engagement with the movable contact member when the other is in engagement with the co-operative contact member.

Telephones:—

TELEPHONE. C. F. Dunderdale, Chicago, Ill., 556,496. Filed May 24, 1895.
Details of construction relating to a granulated carbon transmitter.

TELEPHONE SWITCHBOARD. I. Anderson, Saginaw, Mich., 556,609. Filed July 8, 1895.
Details of construction whereby a central station is obviated.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED MARCH 24, 1896.

Accumulators:—

ELECTRODE FOR SECONDARY BATTERIES. O. Pirsch, Liege, Belgium, 556,769. Filed March 11, 1895.
Thin sheet lead provided on both faces with outwardly flaring tubular projections.

SECONDARY BATTERY. M. Sussmann, Neu-Ruppin, Germany, 556,782. Filed May 15, 1895.
Comprises a sheet metal conductive core and an active material consisting of a paste composed of a plumbic material and pumice-stone, and a solution of rubber.

Alarms and Signals:—

BLOCK SYSTEM FOR RAILWAYS. B. C. Rowell, Boston, Mass., 556,773. Filed Dec. 16, 1893.
Two opposed signal apparatuses; mechanism connecting them and keeping them always in opposed positions.

Batteries:—

ZINC SUPPORT FOR BATTERIES. H. J. Brewer, New York, 556,048. Filed June 9, 1894.
Employs two downwardly projecting arms engaging with the two sides of the spout of the jar.

CONDUCTOR FOR ELECTRICAL DECOMPOSING TANKS. J. Leith, St. Helen's, England, 556,854. Filed Nov. 20, 1895.
Stranded wires or strips, each strand individually connected to the anodes.

Conductors, Conduits and Insulators:—

ELECTRICAL CONNECTOR. B. L. Toquet, Westport, Conn., 557,037. Filed Dec. 28, 1895.
A tube for a joint for electrical conductors indented to form an internal central stop.

Distribution:—

CONVERTER OF FREQUENCY FOR ALTERNATING ELECTRIC CURRENTS. M. Hutin and M. Leblanc, Paris, France, 556,094. Filed March 13, 1894.
Consists in successively and continuously changing the points of line connection in either direction around a commutator apparatus.

ALTERNATING CURRENT SYSTEM. E. W. Rice, Jr., Swampscott, Mass., 556,865. Filed Jan. 24, 1894.
A three-phase generator, in which the different armature coils are wound with wire of different section corresponding to the strength of the current they are designed to generate.

Dynamos and Motors:—

WIRE GAUZE BRUSH FOR DYNAMOS OR MOTORS. A. B. Soar

and E. W. Collier, London, England, 556,870. Filed Dec. 7, 1895.
Superposed layers of corrugated wire gauze.
SUPPORT FOR FIELD MAGNET COILS. B. G. Lamme, Pittsburg, Pa., 556,891. Filed Sept. 4, 1895.
Comprises a body portion in one plane and integral flanges in planes perpendicular thereto.

Electrometallurgy:—

PROCESS OF AND APPARATUS FOR PRODUCING METALLIC COMPOUNDS BY ELECTRICITY. E. N. Dickerson, New York, 557,057. Filed June 5, 1895.
Method of producing calcic carbide by a process of continuous feeding of material between the arcing electrodes.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. G. C. Pyle, Indianapolis, Ind., 556,898. Filed May 2, 1895.
Especially intended for locomotive headlights.
ELECTRIC SIGNAL LAMP. A. F. Ward, Memphis, Tenn., 556,946. Filed June 21, 1895.
A dynamo, a hand-driven mechanism therefor, a folding mast and a signal lamp at the upper end of said mast.
MEANS FOR ATTACHING AND DETACHING ELECTRIC LAMPS. F. A. Butterfield, Detroit, Mich., 556,959. Filed June 1, 1895.
A gripping arrangement for removing lamps in inaccessible places.

Miscellaneous:—

ELECTRIC ELEVATOR. E. W. Rice, Jr., Schenectady, N. Y., 556,866. Filed April 2, 1890.
An electrodynamic machine constructed to operate as a motor in causing the car to ascend and be operated on a short circuit as a generator by the car in descending.
DEVICE FOR PLACING ELECTRIC BLASTING FUSES. R. H. Elliott, Birmingham, Ala., 556,882. Filed July 13, 1895.
The wires are only insulated by wound insulation for a short distance from the fuse, and are then held between superimposed slabs of wood.
THERMO-EXPLOSIVE CARTRIDGE. C. H. Rudd, Chicago, Ill., 556,901. Filed Dec. 26, 1893.
Augments violence of chemical combination of explosive substances by means of heat applied when the explosion is desired.
ELECTRICAL DETONATOR. C. H. Rudd, Chicago, Ill., 556,902. Filed Feb. 3, 1894.
Relates to above.
ELECTRICAL DETONATOR. C. H. Rudd, Chicago, Ill., 556,903. Filed Feb. 3, 1894.
Relates to above.
ELECTRICAL DETONATOR. C. H. Rudd, Chicago, Ill., 556,904. Filed Feb. 3, 1894.
Relates to above.
ELECTRIC RECORDING INSTRUMENT FOR SHIPS' COMPASSES AND LOGS. C. L. Jaeger, Maywood, N. J., 556,987. Filed Jan. 25, 1894.
A conducting disc having projections, a conducting arm actuated through suitable mechanism and arranged to rotate close to the conducting disc, an induction coil and a recording device.
LIGHTNING ROD BALL. E. K. Hum, Pittsburg, Pa., 556,984. Filed Jan. 5, 1895.
Of silvered glass, having an interior coating of asphaltum or paint.

Railways and Appliances:—

TROLLEY SUPPORT. E. B. W. Reichel, Gross-Lichterfelde, Germany, 556,864. Filed Sept. 3, 1895.
Relates to a trolley base.
CLIP FOR TROLLEY WIRES. R. H. Beach, East Orange, N. J., 556,876. Filed April 17, 1895.
Comprises pivoted clamping members adapted to engage and hold the trolley wire.
ELECTRIC CAR TRUCK. E. Lundqvist, Pittsburg, Pa., 556,893. Filed July 31, 1895.
The motor is supported entirely upon the truck frame.
TROLLEY ATTACHMENT FOR ELECTRIC CARS. F. S. Smith, Hartford, Conn., 556,941. Filed June 11, 1895.
Allows trolley to drop whenever pressure of flanged wheel against conductor is relieved.
SAFETY DEVICE FOR ELECTRIC CARS. A. H. Wheeler and J. Gilbert, Warwick, R. I., 556,949. Filed Jan. 2, 1896.
An emergency track brake operated by a lever on platform.
INSULATED SUPPORT FOR CONTACT RAILS. A. Hanson and J. R. Chapman, Chicago, Ill., 556,971. Filed Oct. 30, 1895.
Details of construction.
ELECTRIC TROLLEY. G. R. Mitchell, Newtown, Pa., 557,008. Filed Nov. 22, 1895.
Designed for use on double track railways, having one common overhead conductor.
TROLLEY FOR ELECTRIC RAILWAYS. P. F. O'Shaughnessy and O. T. Crosby, New York, 557,015. Filed Sept. 27, 1888.
A trolley for making an underneath contact with a conductor, a telescopic support for the trolley on the roof of the car, and means extending within reach of the operator for adjusting the trolley.
MEANS FOR SUPPORTING MOTORS AND MOTOR FRAMES. E. S. Breed, New Britain, Conn., 556,049. Filed April 22, 1895.
Details of construction.

Regulation:—

OPERATING DYNAMO ELECTRIC MACHINES IN MULTIPLE. E. Verstraete, St. Louis, Mo., 556,788. Filed Sept. 1, 1894.
A generator having series field coils and field coil in shunt relation to the armature, and other generator supplying the same circuit in multiple, having a set of shunt field coils energized by current taken from opposite sides of the armature of the first generator.
CONTROLLER FOR ELECTRIC MOTORS. E. D. Priest, Schenectady, N. Y., 556,862. Filed April 9, 1895.
A reciprocating resistance switch, a separate reciprocating series parallel switch, and permanently connected means for operating the two switches simultaneously from a single handle.
REGULATING DEVICE FOR CONTROLLING WORKING OF ELECTROMOTORS. R. Thury, Geneva, Switzerland, 556,945. Filed Feb. 3, 1896.
Adapted to railway use.

Switches, Cut-Outs, etc.:—

ELECTRICAL CONNECTOR. P. H. Fielding, New York, 556,967. Filed July 9, 1895.
A bottomless stage or floor pocket, the object being to prevent contact by anything falling therein.
AUTOMATIC GROUNDING DEVICE FOR ELECTRIC CONDUCTORS. G. A. Jewett, Chicago, Ill., 556,823. Filed July 8, 1895.
A part electrically connected with the ground, a second part which is movably attached to a support and which bears against but is unattached to the wire.

Telephones:—

TELEPHONE SWITCH. W. A. Moore, Brooklyn, N. Y., 556,763. Filed Sept. 5, 1895.
The removal of receiver opens switch.

REPORTS OF COMPANIES.

NEW YORK EDISON EARNINGS.

The Edison Electric Illuminating Company, of New York, reports its February earnings (inclusive of high tension systems) as follows:

	1896.	1895.	Inc.
Gross	$195,221.23	$176,715.44	$18,505.79
Net	103,4[illegible].37	82,680.13	20,754.24
Gross, 2 months.........	413,402.77	382,357.97	31,044.80
Net, 2 months...........	220,2[illegible].57	186,998.52	33,291.05

WESTINGHOUSE COPPER MINES.

A special dispatch from El Paso, Tex., of March 24, says: The Westinghouse interests have secured control of the Washington Camp group of copper mines in Pima County, Ariz., the heaviest producing copper properties in the Territory, and took possession of the defunct International Copper Smelting Plant in this city to-day. The price paid for the mines is said to be $70,000, but developing will make them worth very much more than that sum.

A well-founded rumor is that a new smelter of six or eight stacks will be erected by the Westinghouse Company at this central point, and an extensive industry inaugurated to supply the Westinghouse Company with copper for manufacturing purposes. The copper is of the very best.

COMMERCIAL CABLE CO'S. ANNUAL REPORT.

The annual statement of the Commercial Cable Company for 1895 was submitted to the shareholders at their annual meeting last month. The gross earnings amounted to $2,009,738.14, and the working and other expenses to $794,340.53, leaving a balance of $1,215,397.61.

There was an increase in the earnings of $236,304.10, and an increase in expenses of $31,344.69, as compared with the previous year, resulting in an increase in net earnings of $204,959.41.

Dividends of 1¾ per cent. for the quarters ending March 31, June 30, Sept. 30, and Dec. 31 have been paid, a total of 7 per cent. for the year on the capital stock, amounting to $700,000. The reserve fund has been augmented by the purchase of $200,000 United States Government bonds. The balance of the year's profit, amounting to $315,397.61, remains to the credit of profit and loss.

The following directors were elected for the year: J. W. Mackay, James Gordon Bennett, George G. Ward, Sir Donald A. Smith, Sir William C. Van Horne, Clarence H. Mackay, T. Skinner, G. G. Howland, C. R. Hosmer, R. Irvin, G. S. Coe, A. B. Chandler, F. C. Platt.

LEGAL NOTES.

THE VAN DEPOELE PATENT CONTEST.

The Kelsey Electric Railway Specialty Company has appealed to the United States Circuit Court of Appeals at New Haven, Conn., from the order of Judge Townsend granting a preliminary injunction in favor of the Thomson-Houston Company, enjoining the manufacture by the Kelsey Company of a trolley base. The ground of the appeal is that there was no evidence in the case of the Kelsey Company's intention to aid in the infringement of the Van Depoele patent. The Kelsey Company was sued as a contributory infringer, it having manufactured merely the trolley base, which it is claimed was not covered by the patent specifications.

BROOKLYN BOARD OF ELECTRICAL CONTROL.

Assemblyman Perkins has introduced a bill in the New York Legislature which replaces the Brooklyn Electrical Subway Commission by a Board of Electrical Control, to consist of the Mayor and the two present Commissioners, Professor George W. Plympton and Frederick R. Lee. Like the present law, the bill provides that on Nov. 1 the powers of the board shall vest in the Mayor and City Works Commissioners.

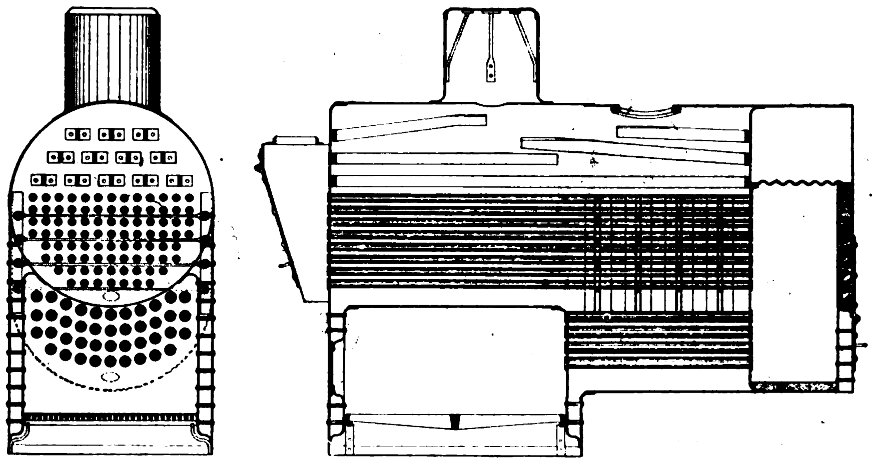
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE ECLIPSE BOILER.

The accompanying engraving represents the Eclipse return tubular boiler. Great care has been taken to distribute the heating surface in a manner to effect rapid and efficient absorption of heat. As much heating surface as possible is brought in direct contact with the fire, and it is claimed more heating surface is secured than in any other internally fired boiler yet introduced. The design also secures sufficient distance of travel of ignited gases to take up all effective heat.

Boilers of this type have heretofore been made with cast iron furnaces, lined with loose firebrick. The great loss of heat by radiation through the sides and front of such furnaces is not only a direct loss of efficiency, but subjects firemen to the discomfort of working in a high temperature, which is avoided with the Eclipse boiler. The absence of water sides and fronts in other boilers of this type is a serious loss of effective heating surface, it being estimated that one-holf the total heat evolved by combustion of coal on the fire-grate of a steam boi er is given out by radiation to the heating surfaces of the firebox. It has been determined by experiment with a locomotive boiler that one square foot of firebox heating surface evaporates from twenty-six to twenty-eight pounds of water per hour.



THE ECLIPSE BOILER.

The Eclipse boiler occupies but little space, and combines the safety of the stationary return tubular type with portability. The front end of the boiler is cylindrical in form, and extends over the furnace, forming the crown sheet. The construction of other parts will be readily understood by reference to the engraving. The crown sheet, being cylindrical in form, is self-sustaining, and does not require bracing. All handholes are so placed that the boiler is readily accessible at all necessary points for cleaning and repairs.

This boiler, which is built by the Kingsford Foundry and Machine Works, of Oswego, N. Y., is made of homogeneous steel plate of 60,000 pounds tensile strength per square inch. All flat surfaces are thoroughly stayed and braced, complying in this requirement with the marine laws of the United States, no stay or brace being subjected to a greater strain than 6,000 pounds per square inch of section.

ANTI-BELL ASSOCIATION IN IOWA.

A special dispatch from Des Moines, Ia., of March 18, says: At the meeting to-day of the anti-Bell telephone companies in the State, nineteen exchanges were present. An organization was perfected, to be known as the Iowa Telephone Association. The companies represented have an aggregate of over $1,000,000 paid-up capital. They have in operation, in addition to thirty exchanges in larger towns, about 2,000 miles of toll lines. The purpose is to connect the systems throughout the State. Practically every part of the State was represented, over forty members being present. A number of the companies operate several exchanges. The association will also control lines in parts of Minnesota and South Dakota.

The association decided on building toll lines from the north and south into Des Moines to connect the systems of toll lines in the north and south part of the State. It is also probable that the association will establish in the State a factory by which all telephone supplies will be manufactured.

E. H. Martin, of Webster City, presided, and E. H. Haines, of Oskaloosa, was secretary. The following concerns were represented by the officers of each that are named: Boone County Telephone Company, of Boone, J. L. Stevens, president, C. E. Wells, secretary, W. H. Crooks, treasurer; Marshall Telephone Company, A. A. Moore, president; Cedar Valley Telephone Company, Waterloo, C. F. Bennett, secretary; Charles J. Cockerill Telephone Company, of Jefferson, C. G. Cockerill, president; the E. H. Martin Telephone Company, of Webster City; E. H. Martin, president; Clearfield and Mount Ayre Telephone Co., H. Baum, president; Clearfield and Lenox Telephone Co., F. A. Ferguson, secretary; Perry Telephone Company, of Perry, George N. Bandy, manager; Iowa and Dakota Telephone Company, of Parker, S. D.; W. A. Houts, secretary; Home Telephone Company, of Sioux City, F. A. Durnell, director; Mutual Telephone Company, of Des Moines, A. T. Hess, manager; Sioux City Telephone Company, H. O. Woodruff, manager; Home Telephone Company, of Oskaloosa, S. T. Slade, manager, and E. K. Hines, secretary; Tri-City Telephone Company, of Clinton, C. B. Miller, manager; Western Telephone Construction Company, of Chicago, J. F. Keelyn, president.

Various committees were appointed, and the following officers were elected:

President, E. H. Martin, Webster City; vice-president, E. T. Hess, Des Moines; secretary, Ed. K. Haines, Oskaloosa; treasurer, S. T. Slade, Oskaloosa; executive committee, Charles E. Wells, Boone; C. F. Bennett, Waterloo; F. A. Durnell, Sioux City; George N. Bandy, Perry.

The chairman stated that the business of the independent companies had increased 50 to 100 per cent. during the last year.

The association will build an exchange in Des Moines in case the company now planning to do so does not succeed.

BERLIN IRON BRIDGE CO.

The Berlin Iron Bridge Company, of East Berlin, Conn., have a contract with the Carteret Steel Co., of Carteret, N. J., for a steel frame to support the furnaces which are to be placed in the new iron building which the Berlin Company is erecting for them.

The Michigan-Peninsular Car Company, of Detroit, Mich., have placed a contract with the Berlin Iron Bridge Co. for a new foundry building, 160 feet square. This building is one story high, has a steel framework throughout, and is so designed that the lower chords of the trusses support runways extending the whole length of the building. These runways carry trolleys having a capacity of 2,000 lbs. By means of these overhead trolleys the molten metal is conveyed quickly and easily from the cupolas to any part of the casting floor.

LINK-BELT MACHINERY COMPANY.

The catalogue of the Link-Belt Machinery Company, Thirty-ninth street and Stewart avenue, Chicago, and New Orleans and New York, reads like a concentrated disquisition on modern mining machinery. The dimensions of the catalogue have advisedly been fixed at 6 x 9 inches, the size recommended by the American Society of Mechanical Engineers as a standard for machinery catalogues, for the pamphlet will be kept

by many of its readers as a work of reference. The cuts and the whole get-up of the work are admirable, and its contents are highly instructive. They show conclusively that electric coal mining machinery has been reduced to a thoroughly practical basis; that it concentrates the workings in the mine and reduces the expense from dead work. It enables the entries to be driven and the rooms to be turned more economically and gives a ready power for drilling, hauling, hoisting, pumping, ventilating and lighting. Electrical machinery adapted for all these operations is described in the catalogue. Among the most interesting features of the pamphlet are the illustrations of the storage plants used for the storing and reloading of coal, some of which have a capacity of hundreds of thousands of tons.

GENERAL ELECTRIC HOISTS.

THE application of the electric motor to portable hoists for derricks is illustrated admirably in the two hoists which the General Electric Company has lately furnished the United States Government, in connection with an important electrical installation. These hoists are of the double drum and single

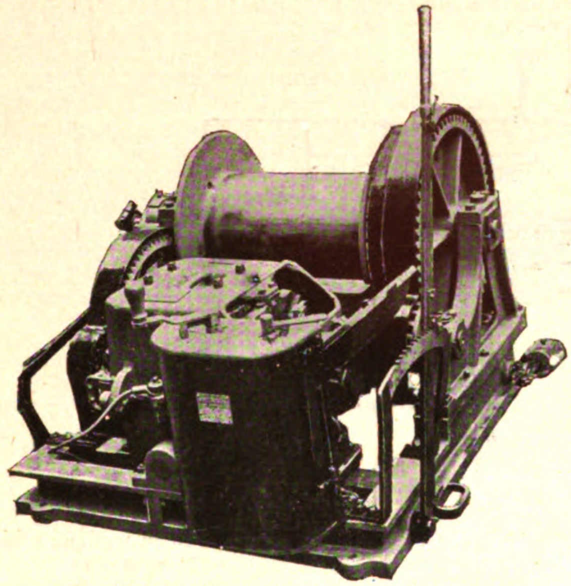


FIG. 1.—GENERAL ELECTRIC HOIST.

drum type, respectively, the double drum hoists being operated by a 20-horse-power motor, the single drum hoist by one of 10 horse-power. Each motor is mounted upon the same bed plate as the hoist and is of a late and efficient type, resembling in general appearance the well-known railway G. E. 800. The parts of the motors are all readily accessible for examination and repair, but are entirely covered in by the motor casing and are thus fully protected against dust, moisture and mechanical injury.

The armatures are iron clad, each coil lying in a slot in the iron core entirely below the outside surface. The motors are sparkless and the bearings are self-oiling. The controllers are known as M. R., and embody all the excellent features of the controller K2 used in street car work.

The levers for the brakes, controllers, etc., are so arranged that full control of the entire mechanism is had without change of position by the man in charge. The hoists themselves are from the works of the Lidgerwood Company. The drums are 14 inches in diameter and 26 inches long.

THE CRANDALL ELECTRIC SIGNAL.

Secretary Herbert, members of the Senate and House Committees on Naval Affairs, General Greely, Chief Signal Officer, U. S. A.; General Flagler, Chief of Ordnance, U. S. A.; Rear Admiral Ramsay, Chief of Navigation; Commodore Hichborn, Chief Constructor; General Dumont, Supervising Inspector General of the Steamboat Inspection Service; Superintendent Kimball, of the Life-saving Service, and a number of other officials, witnessed on March 24 an exhibition of a new electric signal for use at sea and on land, the invention of L. S. Crandall. The exhibition took place in the sub-basement of the Navy Department building and was conducted by the inventor. A display frame, containing numerous incandescent electric light lamps, so arranged as to contain all the elements of every letter in the alphabet, composes the signalling apparatus proper. To this is attached a keyboard similar to that of a typewriter, and, pressure on each lettered key so switches the current that the letter indicated is formed in brilliant curves and hues. It is claimed that the device will show plainly at the distance of five miles.

A SUCCESSFUL WOMAN INVENTOR.

The progress now being made by the New Woman is illustrated in the recent success of Mrs. Lottie Cox, of Blue Springs, Nebraska, who has just been awarded a prize of $150 for the best and simplest invention submitted to the patent firm of John Wedderburn & Co., Washington, D. C.

Mrs. Cox is the first woman who has been successful in these monthly competitions which have now been in progress for the past year. She is forty years of age and styles herself a "self-made woman." She was left a widow at twenty, with two small children, and thrown entirely on her own resources. While engaged in daily labor to support herself and children, she experimented with various ideas, and finally evolved a work table, supplied with numerous conveniences much appreciated by women. Although somewhat stinted as to means, she bravely undertook to patent her invention, and, having submitted it to Messrs. Wedderburn & Co., in connection with their patent awards, received the prize of $150 in the February contest.

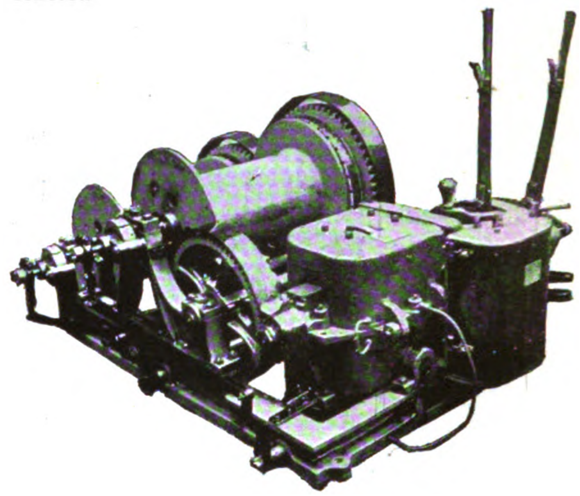

FIG. 2.—GENERAL ELECTRIC HOIST.

Mrs. Cox declares she is much encouraged at her success, and hopes to follow it with the completion of other inventions now under way. This would seem to be a most edifying example for the emulation of her sisters, who are now absorbed in the endeavor to imitate men in far less profitable enterprises.

NATIONAL UNDERGROUND CABLE CO.

Mr. Edwin S. Reid, who has been with the Standard Underground Cable Company for many years, as superintendent of construction, has severed his connection with that company and has accepted a position with the National Underground Cable Company, with main office at New York and branch offices at Chicago, Philadelphia, and Boston, as its general superintendent of construction, and all construction work done by the National Company will be under his immediate charge and supervision.

Mr. Reid, who was for many years associated with Mr. Stephen D. Field, in his various electrical works, entered the underground cable business in its earliest days, and many of the appliances used on underground cable work, which have tended to make underground cables successful are of his invention and design.

The well-known Reid cable terminal, which was invented by him only a few years ago, has given such satisfaction and met the requirements of the users so well that over 100,000 of them are in use to-day in the United States and Canada on telephone, telegraph and electric light cables for underground and aerial service.

There are but few underground systems in the United States which Mr. Reid has not had something to do with, and his experience covers not only the construction of cables, but also the building of complete subway systems; and, besides, he has the advantage of being able to make the most delicate and complicated electrical tests, and of being master of electrical subjects generally.

Mr. Reid has already started in on his work with the National Underground Cable Company, and in the hands of one so competent, the most satisfactory results are certain to be obtained.

The National Company is certainly surrounding itself with the most competent men obtainable, and is to be congratulated upon its enterprise and progressiveness.

A MICA SAMPLE CARD.

Eugene Munsell & Co., 218 Water street, New York, importers and wholesale dealers in India and Amber mica, are sending to the trade a large sample card, showing a variety of forms of mica for electrical insulation, stamped solid mica segments for all the standard railway motors, mica washers, etc. At the top of the card appears the company's name and address, in heavy, bold type, as importers of pure India mica for electrical insulation, and the statement that the mica can be furnished in Amber quality. The lower part of the card is given up to the list of agencies in the principal cities—Chicago, W. H. Sills & Co.; St. Louis, A. S. Partridge; Cincinnati, Sinclair Randall; Cleveland, the Cuyahoga Supply Company; San Francisco, J. W. Brooks & Co. The company is in a position to furnish mica in both India and Amber quality; in the sheet, or cut to any size or pattern; mica segments gauged to thickness for all the standard railway motors.

LUNDELL FAN MOTORS.—"WHITE WINGS."

THE Interior Conduit & Insulation Co. have issued a handsome and complete catalogue, showing their line of Lundell fan motors for the season of 1896. These machines—some 20,000 of which are now in actual use—are so well known throughout the country that a description of them is entirely superfluous. Special mention, however, should be made of several new styles which are now offered for the

LUNDELL CEILING FAN.

first time. The Lundell "White Wings," illustrated, is a decided novelty. This is a ceiling fan motor with aluminum blades, made in two sizes, and especially adaptable for low studded ceilings. The outfits are complete and most efficient, of handsome design, and are very low-priced. New designs in suspended and bracket fan motors are also shown in the catalogue. This large and varied line of Lundell fan motors will meet with the commendation and recognition of the trade at large.

THE NEW YORK ELECTRIC FACTORY.

J. L. Ludwig, connected with the Walker Company, of Cleveland, O., which is to locate here in a factory on Winchester avenue, is in the city and will take charge of the operators. He expects to open the factory in about six months with a few men and increase the number as fast as business will warrant it. He will employ New Haven men. He confirmed the statement that the Walker Company had purchased the machinery and business of the Consolidated Electric Company, of Boston, and added that the business previously done by that company, what was left of that done by the Standard American Electric, the former occupant of the Winchester avenue factory, and certain kinds of work being done in the Cleveland factory of the Walker Company, would be done in the factory in this city.—New Haven "News."

ROCHESTER, N. Y.—The Irondequoit Park R. R. Co., of Rochester, N. Y., have contracted with W. J. Creelman, of that city, agent of the Stearns Manufacturing Co., for their complete power equipment, consisting of two 100-horse-power Woodbury engines, two 100-horse-power boilers, line shaft, pump, heater, etc. The road will be in operation early in May.

WHERE THE NEW COPPER GOES.

A good idea may be gathered of the extent to which transmission of power by electricity is gaining ground in this country by the statement, that in the long-distance plants installed by the General Electric Company during 1895, over 1,200 miles of copper wire for transmission purposes alone were used, amounting practically to 1,200,000 pounds of copper.

UNDERGROUND CABLES FOR THE BOSTON WEST END RAILWAY.

The National Underground Cable Company has just received an order from the West End Street Railway Company, of Boston, covering all the lead-covered underground feeder cable to be used by the latter company during the year 1896.

The first work to be done on this contract will be for about twenty-one miles of 500,000 circular miles cable and two miles of 1,000,000 circular mils cable. The West End Company has been using for some time large quantities of the National Company's cable, and the giving of this order speaks for itself as to the quality of the cable and the satisfaction it has given. This contract of the National Underground Cable Company covers also the laying and connecting of the cables in Boston, and the doing of all the work.

WESTERN NOTES.

MR. C. O. BAKER, who was recently appointed manager of the Western office of the Anchor Electric Company, of Boston, Mass., is now settled in his new quarters, 1654-5-6 the Monadnock, Chicago, where he has a complete line of samples of the electrical goods manufactured by his company.

MR. J. E. WAY, New York, manager of R. Thomas & Sons headquarters at the office of Grier Bros., who are Western agents for the concern.

MR. THOS. GRIER will read a paper on April 17 on "Little Economies in Central-Station Practice," before the Chicago Electrical Association.

THE AMERICAN CIRCULAR LOOM COMPANY, 1114 the Marquette Building, Chicago, have just issued a new alphabetical directory of all the office buildings in Chicago, with their locations. This little book, which is very tastefully got up, has a complete list of all the buildings in the Western metropolis, which number some 200. It will supply a long-felt want, and will be of great use not alone to strangers who visit the city, but to many who reside there permanently, as even numbers of the latter are often at a loss to locate readily some of the many small office buildings with which the city abounds. The book, which is vest-pocket size, has a neat, dark-colored leather paper cover with its title and the publishers' names printed on the front.

MR. E. M. SCRIBNER, who has for a considerable time been connected with the Western Electric Co., Chicago, is about to sever his connection with that concern, and will, after April 1, enter another responsible postion with the Bryant Electric Co., at their factory in Bridgeport, Conn. Mr. Scribner has the best wishes of his friends for his future success.

MR. J. D. M'INTYRE, representing Pass & Seymour, Syracuse, N. Y., was a Chicago visitor last week.

THE ELECTRIC APPLIANCE COMPANY is distributing two catalogues which should be in the "catalogue library" of every electric light station in the country. One of these is their catalogue of Paiste specialties, and the other of P. S. porcelain specialties. Both of these catalogues are supplied with special trade discount sheets, giving the latest and lowest trade prices on these goods, and are hence valuable information to the close buyer. Copies will be cheerfully furnished on application.

THE TRUMP MANUFACTURING COMPANY, of Springfield, O., has secured an order from the Street Railway Company of Oswego, N. Y., for two Trump turbines. They are for the new power house to be built on the site of some old mills, and will develop 642 horse-power on a horizontal shaft.

DENVER, COLO.—Incorporation papers have been filed in Denver, Colo., for a company, the purpose of which is to purchase the street, electric and cable railroads of Denver and consolidate them under one management. The capitalization of the company is $3,700,00, and the incorporators are G. H. Holt, C. D. L. Huilen, William Cole and Charles Sheehan, of New York City; Joshua Wilbour, of Providence; Arthur Knight, East Greenwich, R. I., and George E. Randolph, receiver of the cable line of Denver.

ELECTRIC BORING.—Messrs. Siemens & Halske, of Berlin, have recently secured a contract for an electric boring plant for the State salt mines at Hallein. The plant will comprise a high-pressure turbine, coupled direct to a continuous-current dynamo and two boring machines.

A NOVEL STREET CAR IN CLEVELAND.

The Cleveland "Recorder" of March 26 has the following item. The battery used is the Washburn, and the motor was also designed by Mr. Washburn. Mr. Shipherd is a large street railway owner:

J. J. Shipherd, of this city, one of the gentlemen interested in the United Motor Company, which has been conducting a series of experiments in regard to use of storage batteries as a means of propulsion on street cars, stated yesterday that he was very well satisfied with the experiments so far made.

"The theory is a beautiful one," said Mr. Shipherd, "for the new system would do away entirely with expensive power plants and cumbersome, dangerous overhead wires. You see the system we are working on is not to charge a battery and then let it run down, as has been the method in vogue with most inventors, but we carry a gasoline tank, and, by manufacturing our electricity on the car, are able to keep up the maximum of power with the minimum of expense.

"Just as long as the gasoline in the tank holds out, just so long we can run. I could not tell you just how much gasoline we can carry, but I do know that there is enough to make power for 24 hours.

"We have a car running on the Superior street tracks after the cable stops. The work done is very good so far, and we all believe the method of transmitting power now in use will be superseded by the storage battery in time.

EDISON BUYS BACK HIS OWN PHONOGRAPH.

Thomas A. Edison has bought from the New Jersey receiver of the North American Phonograph Company all his own rights and property, and, after a bitter experience rarely equalled by that of any other great inventor, is going to see what he can do for himself with the phonograph.

He has thoroughly perfected and is going to put on the market a cheap spring motor phonograph to sell for about thirty-five or forty dollars, which will run two of the ordinary cylinders on one winding.

The Edison Phonograph Works, near the laboratory, at Orange, will build the apparatus, and the National Phonograph Company, of Orange, N. J., has been formed to handle the selling end of the business. Hitherto, there has been a territorial system, like that of the telephone, but the new company has determined to get right to the people by appointing selling agencies in all of the large cities throughout the country like those for the sewing machine and bicycle.

MR. FRANK H. BALL.

The American Engine Co., Bound Brook, N. J., have secured the services of Mr. Frank H. Ball as manager of their business. He will add to their present line of steam and electrical machinery a full line of his celebrated engines, especially adapted for direct connected electrical work.

Mr. Ball is widely known as one of the best engineers in this country, and the American Engine Co. are to be congratulated on the new order of arrangements.

NEW YORK NOTES.

MR. L. J. MONTGOMERY, Secretary of the Electricity Newspaper Co., who has been with that firm since its inception, has resigned his position, in order to take charge of the business department of another publication.

R. HOE & CO., of New York City, manufacturers of printing presses, have placed an order with the Berlin Iron Bridge Company for an all-steel building for storage purposes. This building is 40 feet wide and 60 feet long, 3 stories high. It is absolutely fire-proof. To avoid condensation of moisture, the roofs and sides are lined with the Berlin Company's patent anti-condensation fire-proof lining on the underside of the corrugated iron covering. The floors are concrete, supported by corrugated iron arches, resting on I-beams. A traveling crane is attached to the trusses, having a capacity of 3 tons, and so arranged that it takes the material to be raised in the building from the lower floor, and raises it to any part of the building on any of the floors. It is a very conveniently arranged and compact storehouse.

MR. C. O. MAILLOUX, the consulting electrical engineer, has of late found his business increasing so rapidly that he has had to move to the American Tract Society Building, where he has double the amount of floor space occupied by his offices hitherto, and where he will have improved facilities for drafting, etc.

THE ROESSLER & HASSLACHER CHEMICAL CO., of New York, are having a brisk demand for barium platino cyanide and ammonium platinum cyanide, both of which chemicals are extensively used in X-ray experiments. There appears to be a greater demand for these goods than ever, and this company are particularly well equipped to furnish this necessity in any quantity.

MR. A. A. DE BONNEVILLE, the popular steam pump salesman and engineer, has resigned his position with the Geo. F. Blake Manufacturing Company, and will in the future represent M. T. Davidson, manufacturer of steam pumps, at 133 Liberty street, New York.

J. H. M'EWEN MANUFACTURING COMPANY, Havemeyer Building, have issued a neat and interesting illustrated catalogue on their Thompson-Ryan direct current multipolar electric generator which has lately received so much attention.

THE ELECTRIC LAMP COMPANY, of Buffalo, has been formed with a capital stock of $100,000. The directors are T. H. Spaulding and J. R. Keim, of New York City; T. F. Crane, of Brooklyn; H. H. Fulton, of Elmira, and D. L. Whittier, of Indianapolis.

THE RUSHMORE DYNAMO WORKS find it necessary to run their factory night and day to keep up with orders for their new lens mirror projectors. The great power of the new projectors, together with their simple construction and perfect performance, has overcome the prejudice which formerly existed, and they are now placing their apparatus on all kinds of vessels on both coasts, the great lakes and Western rivers, besides equipping several warships. They have recently replaced a number of the finest projectors of foreign make, as it was shown that the Rushmore light had four to five times the power for the same current consumption. They are now making their own lenses, and their grinding plant is said to be one of the finest in the country for this class of work.

"THE PHOTOGRAPHIC TIMES" for March contains over 100 pages. The articles are interesting and valuable to camerists and the numerous illustrations are fine specimens of engraving. Considerable space is given to X-rays, one article being contributed by Mr. Osterberg. The "Times" has used the articles in "The Electrical Engineer" of Feb. 5 on Professor Wright's cathodographs and the Moore etheric light, and has also quoted this paper's articles on Professor Röntgen and Mr. D'Infreville's seeing and photographing in the dark.

"HOW TO SPRAY" is the main title of a clever little pamphlet issued by the Goulds Manufacturing Co, of Seneca Falls, N. Y., and devoted to their spray pumps and spray nozzles. It not only contains a mass of trade data relative to pumps and nozzles, but gives a variety of formulas as to solutions for spraying plants and when to use them.

PHILADELPHIA NOTES.

STERN & SILVERMAN have contracted with the Dayton Traction Company, of Dayton, O., for the building of their line from Dayton to Miamisburg, O., a distance of twelve miles. The contract calls for the furnishing of the roadbed complete with bridges, cars, trucks, motors, Corliss engines, boilers, dynamos, and steel and brick carbarn and power station, all to be in operation by July 1, 1896.

THE KENSINGTON ENGINE WORKS, LTD., of Philadelphia, Pa., have recently sold three 100-horse-power return tubular boilers of 125 pounds working pressure to Haddon Hall Hotel, Atlantic City, N. J., also a 200-horse-power feed water heater of special design to the Atlantic Refining Company, of Point Breeze, Pa.

NEW ENGLAND NOTES.

THE AMERICAN ELECTRICAL WORKS, of Providence, R. I., have issued a very pretty calendar with a water-color picture on it of their Phillipsdale mills, into which is also vignetted their large factory in the City of Providence.

MR. ALONZO KEAN, East Boston, Mass., one of the early graduates from the Thomson-Houston Expert Course, Lynn, who was for about eight years in the Construction Department of the Thomson-Houston Electric Company, and about two years in the Construction Department of the General Electric Company, Boston, Mass., has received an appointment as chief electrician for R. H. White & Co's., new plant, Boston, Mass.

MR. F. A. ABBOTT, who was with the Boston Electric Light Company for eight years, and with the Edison Electric Illuminating Company, at 3 Head Place, for the last four years in the Meter Department, has organized the Abbott Electric and Gas Engineering Company in Boston, with offices at 66 Bowdoin street. Mr. Abbott has had wide experience in the electrical field, and has already received indications favorable to his new business.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. APRIL 8, 1896. No. 414.

ELECTRIC LIGHTING.

ARE ROENTGEN RAY PHENOMENA DUE TO SOUND WAVES?

BY

Thomas A. Edison.

FURTHER experiments with the Röntgen ray have developed some new phenomena which may aid in explaining the mode of transmission. In studying various photographs taken in the past month there were certain features which were difficult of explanation except on the theory that the X-ray was a sound wave of very small wave length, and that the shadows were sound shadows, the peculiarities of which are known, one of the best illustrations being the experiments of Le Conte in the Bay of San Francisco, published in the "Philosophical Magazine," February, 1882.

The experiment was briefly this: Le Conte placed a bottle under water on one side of a pile; at a distance of 200 feet from the pile he exploded a charge of nitro-glycerine, also under water. The concussion wave shattered the bottle. He then placed it behind the pile and exploded a charge. The bottle

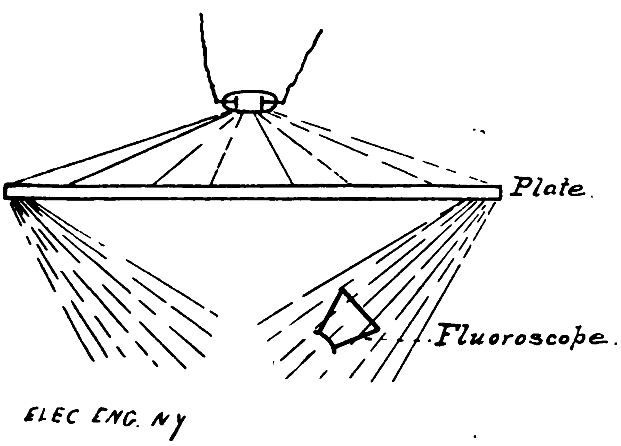

FIG. 1.

was uninjured. In another experiment he placed a glass tube at right angles to the pile, its ends projecting a couple of feet on each side. The portions within the shadow were uninjured, the ends were broken off. I therefore conducted a number of experiments with this theory in mind.

The fluorescent bulb was placed on one side of a steel plate, Fig. 1, the observer being on the opposite side. When the fluoroscope was placed against the steel plate directly opposite the bulb on the other side, no light was observed; but when the fluoroscope was made to approach within six inches of the edge and well within the shadows it lighted up. The direction of the X-ray was found by a moving bar of iron, so as to obtain the sharpest image. Fig. 1 illustrates the direction of the ray as near as possible with the rough apparatus used.

The second fact which possibly tends to confirm the sound wave theory is that liquids do not fluoresce with the ray, at least none that I have tried. Crystals alone fluoresce, except in one or two cases, such as precipitates, and these may not be amorphous. The crystal is resonant to the wave.

The third observation is that a tube with a vacuum so low as to give striae and from which ordinarily no X-ray can be obtained, no matter how long a dry plate is exposed to it, can be made to give the ray by a powerful blast of air on the spark of the break wheel of the primary and a spark gap in the secondary, the wires of which are guarded up to the very end.

Another observation is that the sharpness of the shadow depends on the abruptness of the break. A very weak bulb may be made to give sharper shadows than one giving twice the luminosity in the fluoroscope, which has a connection with this theory. Another fact is, that when tubes are on the pump continuously the vacuum will depend upon the pump, that is, the amount of mercury running per minute. The vacuum will reach a certain stage and keep that way for several days, the pump being able to reach a certain exhaustion, and no further, the air brought in by the mercury being the limiting point.

With Sprengel pumps used for incandescent lamp exhaustion the stage of vacuum reached is rather too high for the best X-ray, but still very good. But if a device is used whereby a definite amount of air is permitted to enter the bulb the X-ray will flash out with great brilliancy in the fluoroscope, lasting for 10 or 15 seconds until the pump has exhausted it to the limiting point mentioned. With this device a moving object can be seen through 30 inches of pine board. By means of the fluoroscope the bones of the arm and shoulder are of extraordinary sharpness.

[For the benefit of our readers we print below the article above referred to by Mr. Edison.—Eds. E. E.]

EXPERIMENTS ON SOUND SHADOWS.

"Experiments with Stout Glass (soda water) Bottles."—In these experiments the observer stood on the top of a vertical cylindrical pile (the trunk of an Oregon pine) about one foot in diameter, situated about forty feet horizontally from the explosive cartridge. The bottle, being secured to a rigid rod, was first plunged under the water from ten to twelve inches behind the pile (Fig. 1, A), that is, within its geometrical shadow. The shock of the explosion did not injure the bottle. It was then plunged into the water in front of the pile (Fig. 2, B), or outside its geometrical shadow. In this position the bottle was

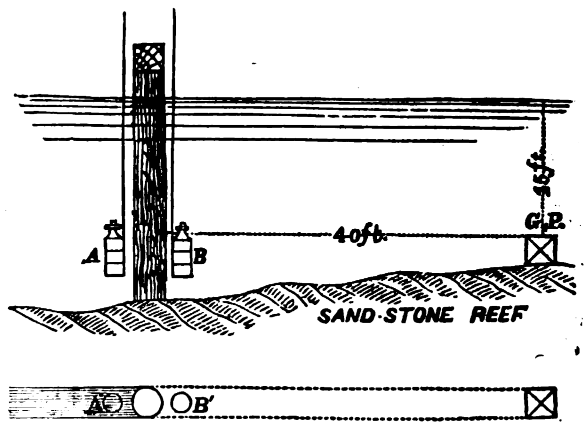

FIG. 2.

shivered to atoms by the concussion due to the explosion. As viewed from the experimenter's situation on the top of the pile, Fig. 1, A' and B', indicate the two positions of the bottle in the preceding experiments.

The experiments were varied by plunging bottles into the water in various positions around the pile, within and outside of its geometrical projection from the explosive center; and in

all cases they were protected from injury when within the geometrical shadow, and were shivered when outside of the same. The same results took place whether the bottles were filled with water or with air.

The breaking of a glass by a sudden shock communicated by means of water is a fact long known, and is illustrated by the old familiar class experiment of exploding a "Prince Rupert drop," while its bulb is plunged into an ordinary apothecary's phial filled with water.

"Experiments with Stout Glass Tubes."—The cylindrical glass tubes employed were about six feet long and 1.5 inches in diameter, the glass being about 0.5 of an inch in thickness. They were covered by pasting cartridge paper over them, so as to prevent the loss of fragments when breakage occurred.

The tubes were adjusted to a framework of wood so arranged that they could be plunged in a horizontal position beneath the surface of the water behind the pile, the axis of the tube being at right angles to the plane of its shadow, and held there (the

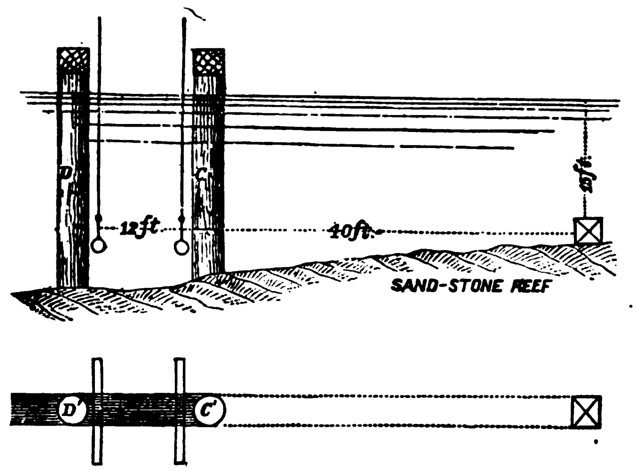

FIG. 3.

observer standing as before on the top) with the middle of the tube in the geometrical shadow, while the two extremities projected on either side about 2.5 feet beyond the boundaries of said shadow (Fig. 3, C and C'). In every case the shock of the explosion shivered the projecting portions of the tube, and left the portion within the shadow uninjured. The boundaries between the broken and the protected portions of the glass were sharply defined.

By standing on the top of a second pile, in the direction of the axis of the shadow of the first pile, and distant about 12 feet, the experiments were varied by plunging the framework and tubes—adjusted at right angles to the plane of the prolonged shadow—into the water at this distance (12 feet) from the obstacle which obstructed the sound wave transmitted by the liquid (Fig. 3, D and D'). The shock of the explosion produced sensibly the same results as when the tube was near to the obstructing obstacle. The protected portion of the horizontal glass tube was sensibly equal in length to the diameter of the pile casting the shadow; hence the shadow of the cylindrical pile extended back for about 12 feet between sensibly parallel vertical planes, and its boundaries, at this distance, were still sharply defined.

DOCTORS TO BECOME CATHOGRAPHERS.

Cathodography will shortly be one of the regular features of the Post-Graduate Hospital, Twentieth street and Second avenue. The utility of taking X-ray pictures in surgery has been demonstrated so often that the hospital authorities have decided to set aside one of the smaller wards for that purpose; and they will equip it with Crookes tubes, Rhumkorff coils, sensitized plates and all the other paraphernalia of the new art. For the generation of electricity they will employ a powerful machine, which has heretofore done service as an ozone generator.

GIFT OF A PLANT TO BLAIRSTOWN, PA.

John I. Blair, a millionaire, has just completed an electric plant at Blairstown, Pa., and presented it to Blair Hall. The plant cost $15,000. The current was turned on for the first time a few days ago, 67 lamps being used to light the town.

THE ROENTGEN RAY SOURCE.

BY

Elihu Thomson

SINCE writing my brief statement, in which it was set out that the anode was possibly the source of the Röntgen rays within the Crookes tube, and not the cathode, I have continued my experiments and investigations and have come to the conclusion that I was mistaken, largely owing to the particular structure of the tubes tested. Indeed, my later experiments have led me to this conclusion, which I think will require no amendment, namely, that the Röntgen rays are produced by the bombardment of any surface within the Crookes tube by cathode rays, or the radiant matter of Crookes; that fluorescence has nothing whatever to do with it, since substances which are bombarded and which do not fluoresce give out the rays—notably a piece of platinum. Lead glass, which fluoresces less than German glass, is still a strong source of the Röntgen rays when bombarded by the cathode rays. I have also been led to the conclusion that the more fluorescence there is produced by the bombardment the less energy will be available for Röntgen rays.

Another result of my observations has been to determine the fact that the Röntgen rays are emitted in all directions from the bombarded surface, and are not special to any particular direction. They are even emitted backward towards the cathode from which the rays which bombard the surface are sent.

In my experiments I find a very convenient way to determine the direction of the rays to be a modification of the fluorescent screen. In this tube a small patch of fluorescent material is mounted at some point between the two ends of the tube itself and backed by dark paper as usual. An opening for the eye is provided at one end of the tube and a moderate size opening at the far end, or the one nearest to the Crookes tube, while the whole screen tube is made of metal to prevent any lateral entrance of Röntgen rays. It will be evident that in this case, when the eye and the fluorescent patch and the distant opening are in line with the source or point of emission of the rays in the Crookes tube, fluorescence will be obtained, but at no other position. Hence, when the tube is so pointed or adjusted that fluorescence is seen it is only necessary to follow back the direction of the tube to lead to the source of the rays. By changing the direction in which observations are made, it is very easily seen that all of the directions determined will converge at some place which is the source of the rays. In this way it was found that with a small piece of platinum in the center of the bulb upon which bombardment occurred from a concave cathode, such platinum became the source of Röntgen rays, and that it did not show the slightest trace of fluorescence.

It was also found that where the rays struck the walls of the bulb, whether they were of lead glass or of German glass, Röntgen rays were emitted in all directions from the place where the radiant matter struck, and that when such rays were projected down and along a tubular extension from the bulb containing the cathode, and opposite which tubular extension the cathode was mounted, the sides of this tubular extension became a source of Röntgen rays, sent out in many directions, even in directions which were towards the cathode terminal.

Since experimenting with the special fluorescent screen which is mentioned above I note that experiments carried out in an entirly different manner by Messrs. Scribner and McBerty,[1] have brought them to the same conclusion, and I also note that Professor Stine has, by following still other methods of investigation, found that the rays are emitted from the bombarded surface. It is interesting, further, to find that, according to an account appearing in "The Electrical Engineer," page 340, an improved tube designed by one of the Professors of King's College, London, has a piece of platinum, which is made the anode for convenience, and which platinum becomes, when bombarded by the cathode rays, the focalized source of Röntgen rays within the tube. I may say that one of the best tubes in my possession, and one which gave the sharpest image, had a piece of platinum foil mounted in the focus of the cathode rays, which platinum foil had become sagged or bent at an angle, its structure resembling the last mentioned tube designed in London except that it had a separate anode.

HOLYOKE, MASS.—The Connecticut River Manufacturing Co., Holyoke, Mass., have purchased a 40-h. p. Ball engine for electric lighting from J. H. Houghton, Boston representative of the Ball Engine Company, Erie, Pa.

I. CENTRALIZING X-RAY BULB.
II. EXTERNAL ELECTRODES VACUUM BULB.

BY WILLIAM JAMES MORTON, M. D.

I.

IN a communication to the March 25th issue of this journal I described an experiment which seemed to demonstrate that the X-ray proceeded from a piece of fluorescent material mounted within the bulb, independent of its walls, and mentioned that I had had constructed and was using a Crookes tube so modified as to embody this idea. The main purpose of the independently mounted fluorescent substance was, as then stated, to receive upon its surface the focused cathodic stream at such an angle that the X-rays might be projected out of the tube in a directive manner. Incidentally I proposed the query, based upon the experiment referred to, as to whether the X-ray might not proceed from the fluorescence only. In this issue I take pleasure in submitting a photographic illustration, Fig. 1, of the centralized X-ray bulb then referred to and described.

The cathode is shown at C, Fig. 2; the anode at A; F, is a piece of fluorescing substance.

The fluorescent material is placed at an angle to the cathodic stream and in such a position as to most conveniently permit of radiation proceeding outward through the sides of the bulb.

I have also had constructed a bulb resembling this one, with

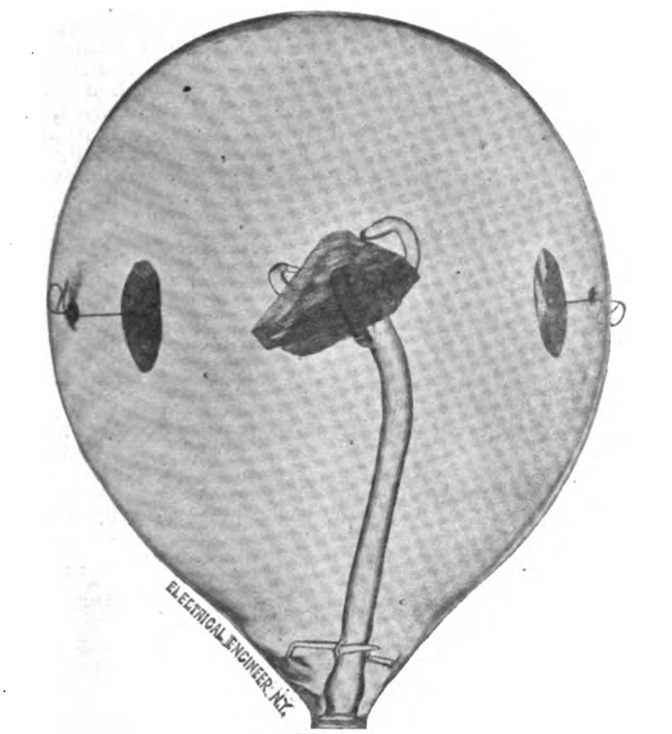

FIG. 1.

the exception that both electrodes focus upon the fluorescent substance.

The bulb illustrated was made for me by Messrs. Eimer and Amend. Any one of a great variety of fluorescent substances may be thus mounted and acted upon.

II.

Unable, like most others interested in making Röntgen pictures, when the announcement of their possibility was first made, to obtain Crookes' tubes, I was forced to turn to other devices of vacuum bulbs.

Omitting details of many experiments, I would like to record, for the benefit of those who wish to work upon this subject, a final form of vacuum bulb which I have arrived at which seems to embody a practical principle of construction, namely, that in a vacuum bulb provided only with external electrodes, the cathodic stream is projected opposite to and against the anodal electrode and its line of projection passes through the anode to reach the sensitized plate.

With this bulb—and it is the only one I, for a long time, used —I made shadowgraphs of the hands, feet, wrist and elbow. It was used with an eight-plate (discs thirty-two inches in diameter) static machine, connected in the circuit existing between the external armatures of Leyden jars, and without a converter of any sort. I found it preferable to use small Leyden jars. But it may also be employed in connection with the induction coil or coil and converter.

The bulb was blown and the vacuum made by Messrs. Eimer and Amend. Reference to the following illustration will enable any amateur to make one: The bulb is about 7½ inches long by 4½ wide. Fig. 3 shows its appearance before the electrodes are fitted to it. Fig. 4 requires a brief explanation. The

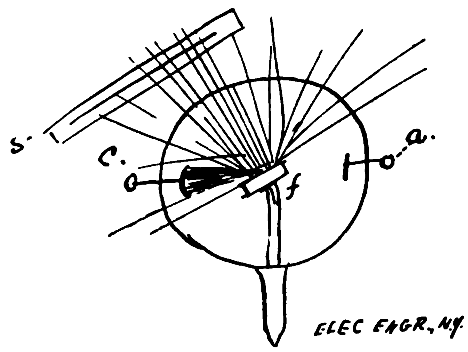

FIG. 2.

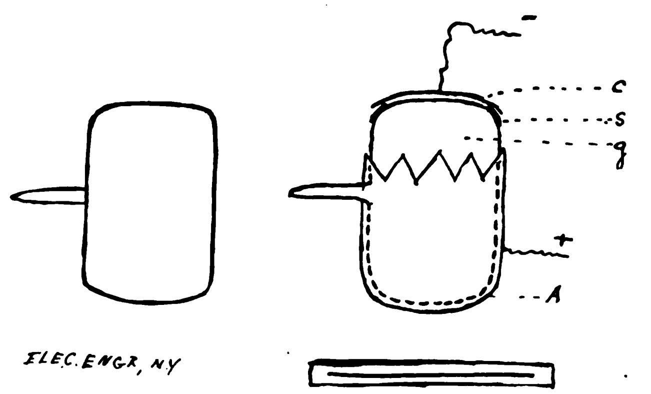
cathode, C, is a disc of thin sheet aluminum about the thickness of ordinary tinfoil annealed and affixed and fitted directly upon the glass with mucilage; its diameter is 3½ inches. Beneath its outer edge is a thick coating and ring of shellac, S, for the purpose of raising the periphery of the cathode disc up and away from the glass, and thus to prevent a possible perforation.

The anode, A, is also of annealed aluminum affixed to the glass bulb with mucilage and completely enveloping its end opposite the cathode and also its sides, with the exception of a small portion of the glass marked g. The anode thus forms practically a metallic cup, within which about two-thirds of the glass bulb sets.

The top of the cup is cut in the form of large serrations in order to provide for a possible sparking over between the two electrodes. If the distance between the two electrodes and the serrations are not properly arranged the glass may be easily perforated.

Running the static machine at fullest practical speed and employing Leyden jars one inch in diameter and seven inches long, coated with tinfoil over one-half of their length, I am able to excite the bulb with a spark extending over a spark gap at the discharging rods of one and one-half to two inches. The cathodic stream from C strikes violently against the opposite end of the tube and causes an active yellowish fluorescence. The sensitive plate is exposed, as indicated, opposite to the anodic end of the tube. The distances I have found most practicable are from 4 to 8 inches. I use a lead diaphragm at the anodic end, having an aperture of from one to two inches.

It will be noted that there is no window or opening in the anode and that the anode, or a considerable portion of it, intervenes between the cathode and the sensitized plate. Should a window be cut in the anodic metal with the hope of getting



FIGS. 3 AND 4.

a better effect upon the sensitized plate the efficacy of the bulb will be greatly diminished.

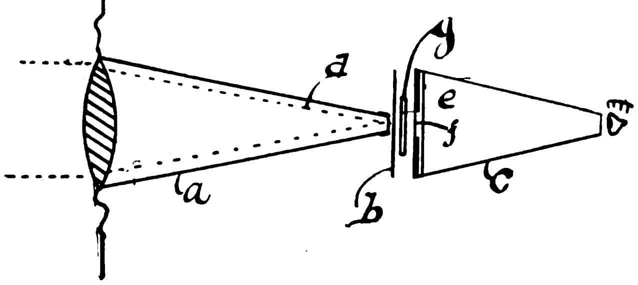
My apology for presenting these details is that this bulb works well with a static machine (or with an induction coil) and that it may prove of interest to many who own such machines to construct their own X-ray bulbs.

PHOSPHORESCENCE AS THE SOURCE OF X-RAYS.

BY EDWARD P. THOMPSON, M. E.

ONE of the most important facts necessary in order to determine the nature of the X-rays is that which will prove their source. In the first place Prof. Röntgen alleges that they radiate solely from the phosphorescent spot upon the Crookes tube. Dr. Morton's experiment indicates the same feature. M. Charles Henry thinks he obtained X-rays from a phosphorescent substance, which he exposed to the light. Niewenglowski finds that phosphorescent bodies increase the penetrating power of sunlight like the sulphide of zinc increases that of X-rays. Poincaré at an early date advanced the hypothesis that the rays are due to phosphorescence, whether produced by electrical or other means. Professors Thomson and Rowland maintain that they radiate from the anode. Tesla has obtained effects by a closed bulb without any electrodes. In one of Tesla's experiments, he employed only one and either electrode, while the other was away off in space somewhere, and yet he obtained penetrating power at great distances. He is convinced that phosphorescence is not the source, because he believes that aluminum X-ray tubes do not phosphoresce. He gave no other explanation. Silvanus P. Thompson thinks that certain of his experiments prove that the rays do not come from either the cathode or from the phosphorescent spot individually, but jointly from both.

I have obtained fluorescence from X-rays after they have passed through a fluorescent substance. Experiments have also proved, apparently, that there are no X-rays radiating from the arc light, sun, flames or other sources of light. Other experiments show that although a Crookes tube may phosphoresce, yet no X-rays can be detected. Sometimes the phosphorescent light is local, occuring in spots here and there. It may be near the cathode or anode, or between them, or as in a tube



DETERMINING THE SOURCE OF THE X-RAY.

with which I experimented, the light was practically uniform on the whole surface, and a fluorescent screen was illuminated by all parts of the Crookes tube equally. Experiment also shows that with a given Crookes tube, the penetrating power of the rays seems to depend upon the electromotive force of the electrical energy, all other things remaining the same. Tesla, with his apparatus, has projected them through the thickest part of the human body, so as to affect the photographic plate.

Upon first reading the statement of Prof. Röntgen as to the phosphorescent spot being the source, it occurred to me that phosphorescence by other means might also radiate X-rays, and I was anxious to learn in the most emphatic manner the truth of the matter, whether it ended in negative or positive results. I have, therefore, been carrying out a series of experiments to determine whether ordinary phosphorscence will produce X-rays. Although I obtained negative results, yet the conclusion should not be drawn to the effect that X-rays may not be obtained by phosphorescence produced otherwise than by electricity, because by no possible means imaginable could I cause light to produce upon a Crookes tube the phosphorescence obtainable by the current, which, as well known, is visible even by daylight. Parenthetically, the intensity of light spoken of in text books is a misnomer. The light considered as to its penetrating power at the focus of the lens is no more intense than elsewhere. It will not penetrate anything to any greater distance by being condensed. It merely appears brighter to the eye, because there is more of it upon a given area, or because more of it has penetrated a given substance. The volume alone is greater.

To determine the degree of phosphorescence obtainable upon a Crookes tube by direct sunlight, it was placed inside of a box having an opening covered by violet glass. When the box was looked into, so as to exclude all other light the tube did not even appear green. However, under the same circumstances, uranium glass, barium platino cyanide, also a screen of ammonium uranate, potassium platino cyanide and others, each appeared of a vivid green or yellowish green. The experiment was repeated with focused sunlight on a very large scale, the lens being about five inches in diameter and having a focus of sixteen inches, and provided also with a funnel, white inside, which brought to a focus much diffused sunlight. The small end of the funnel was located in a dark room. The light was condensed upon violet glass.

The light passed through the glass, and, upon striking the phosphorescent and fluorescent materials, its refrangibility was changed; while the substances were as vividly green as when produced by the radiations in the Crookes tube, and, light cannot cause the same phosphorescence upon a Crookes tube did not become green. Uranium glass seemed as bright as when forming a Crookes tube highly charged. The Crookes tube had been before tested, and showed a green phosphorescence with a high electromotive force. The experiment with violet glass, although perfectly simple, and although the results, perhaps, could have been conjectured, proves that sunlight cannot cause the same pohsphorescence upon a Crookes tube as that produced by the current.

Another experiment indicated somewhat otherwise. In the direct focus, without blue glass, a livid green (as when electrified) was discernible as a fringe around the focus.

Inasmuch as the other substances fluoresced better with the violet light than with the electrified Crookes tube, as far as the eye could remember, an experiment was performed with the apparatus shown in the accompanying diagram, in order to determine whether condensed sunlight would produce sufficient phosphorescence for the generation of X-rays. The funnel above described was closed at the small end successively by different phosphorescent and fluorescent substances, b. The instrument which has now become known as the fluoroscope was directed towards the substance, b; which was made phosphorescent or fluorescent by the condensed sunlight, d, in order to detect fluorescence upon the screen, e, within the fluoroscope, which was covered at the large end partly with one thickness, b, partly with two thicknesses, and on another portion by three thicknesses of black paper.

The fluorescent screen, f, appeared green only at the part covered with one thickness. It was brighter without screen, b, which seems to contradict Niewenglowski's result. If there had been X-rays of any appreciable extent, they would have caused fluorescence through the three thicknesses and through a block of wood, g, interposed between the two fluorescent screens outside of the fluoroscope, as illustrated in the diagram. It should be noticed that the fluoroscope was exceedingly sensitive, and yet the results were negative.

The same instrument was tried with a Crookes tube generating X-rays by a current, and it became uniformly luminous at a distance of six feet from the electrified Crookes tube; therefore, it may be concluded, I think, that X-rays cannot be obtained from phosphorescence produced by sunlight. It may be noted that the objects were not placed exactly in focus because they would burn. The funnel, a, was cut off so that the cross sectional area of the path of the condensed rays was about one-fourth of an inch in diameter, and in this case heat absorbing substances were not needed further than that of the lens itself.

Aluminum was substituted for the block of wood, g, but no fluorescence occurred with the fluoroscope. The experiment was modified in a great many different directions; for example, by using the focused light when reflected from the screen, b, although (as the latter was made of a mixture of pulverized fluorescent material and varnish) the fluorescence was caused by reflection from each particle when the light was transmitted by the screen, as well as when reflected therefrom. A gas flame was also employed as a source of light; also sunlight without a lens.

Remembering how a little daylight entering the eye while viewing fluorescence by X-rays nearly neutralized the effect, I thought, perhaps, persistence of vision prevented my seeing any fluorescence which might have been produced through the three thicknesses of black paper, and therefore I applied the most severe test. A photographic plate with a metal ring attached to it was wrapped closely in several folds of black paper and inclosed in an aluminúm box, which, in turn, was wrapped in cloth. On the outside of all was fastened a plate of uranium glass, which was exposed to direct sunlight for over seven hours. No effect whatever was produced upon the photographic plate. With X-rays, an effect would have occurred through the same thickness in a few minutes.

A large glass plate covered with calcic sulphide, which remains luminous in a dark room after having been exposed to sunlight, was tested. I exposed the plate to the condensed sunlight, forming a bright, luminous spot, and at another time I exposed the whole plate to sunlight for an hour or more. When the fluoroscope was directed toward it in the dark and certain experiments performed, sufficient light was produced

to illuminate the screen in the fluoroscope, but not through even a single thickness of black paper, but only enough to cast a shadow. Here again the bluish brightness of the luminous paint is not visible in daylight, while a Crookes tube energized by electricity radiates green light abundantly and is easily visible in daylight.

While these experiments do not prove that the X-rays do not have their source alone in the phosphorescence of a charged Crookes tube, yet they form substantial evidence that X-rays are not obtained from phosphorescence by sunlight.

ON THE SOURCE OF THE ROENTGEN RAY.

BY

W. M. Stine

A series of experiments extending over the past six weeks has at length yielded conclusive evidence and enabled the source and distribution of the ray to be mapped out around the entire tube with great clearness. Penumbral shadows were repeatedly plotted back to the tube and invariably pointed to

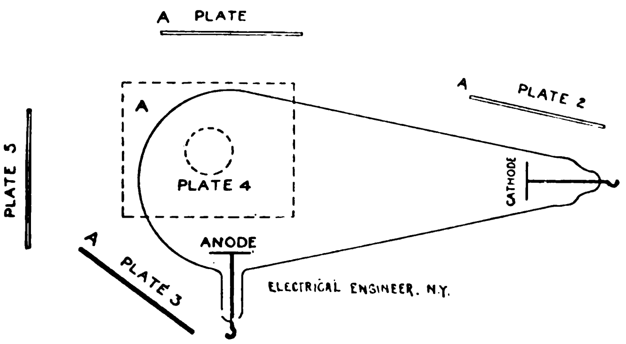


FIG. 1.

the area of the bulb opposite the cathode as the source of the distribution. These observations have already been published.[1]

It occurred to the writer that the best means to trace the ray distribution would be shadows cast by short metallic tubes. Half-inch lengths were cut from No. 18 gauge brass tubing, varying in diameter from ½ inch to 3 inches. In the first experiment, these were placed concentrically on a dry plate and placed parallel with the bulb in position marked 5 in Fig. 1,

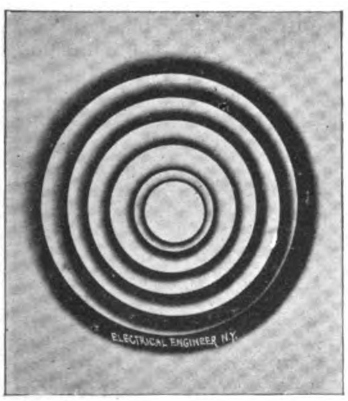

FIG. 2.

the distance of the plate from the bulb being 4 inches. The sciagraph is reproduced in Fig. 2.

Two separate effects are to be noted in all the sciagraphs of the tubes used. Both the length and direction of the shadow are clearly indicated and the vertical shadow of the metal itself. It will be noted that the latter seems to indicate the presence of rays which are more or less vertical. Plotting the shadows in Fig. 2 and noting that the vertical shadow does not appear beyond the third ring, we find that the source of the rays was on the surface of the bulb, and the area of the source was nearly or quite circular, and not much in excess of the diameter of the third ring, which was 1½ inches.

With such a clear and unmistakable result in possession, the next experiment was an attempt to decide whether this area was the only source of the ray. We were guided in this by some recently published emphatic statements that the ray was of anodic origin and did not, as popularly supposed, proceed

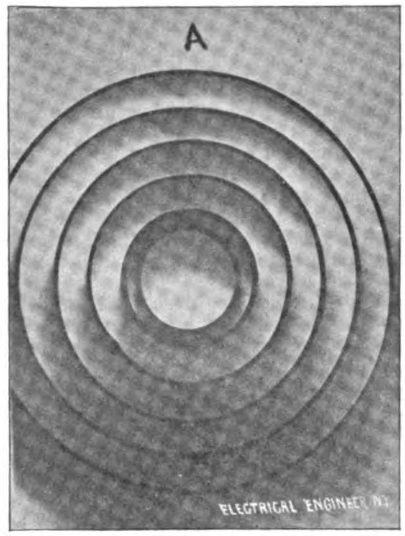

FIG. 3.

from the cathode. It was seen that while a screen could be misleading, the shadows cast by rings would be conclusive. Four plates were prepared for simultaneous exposure. The concentric rings were placed on one plate, and single rings, of 1 inch diameter and same height, were placed over the other plates. All these objects were placed as nearly as possible on the center of the plate. In Fig. 1 is shown the shape of the tube, the position of the electrodes and the plates, which were 3¼ by 4¼-inch in size, and placed 2½ inches from the bulb. The plates were marked with the letter "A" on the ends which were disposed as shown in the drawing. The resulting sciagraph from plate 1, is shown in Fig. 3, that from plate 2 in Fig. 4, from plate 3 in Fig. 5, and from plate 4 in Fig. 6.

To interpret the results, note first the sciagraphic effect of the rings, and second, the elliptical shadows of the intercepted inclined rays. If the latter be plotted, they all point to one area, the circular cathode imprint on the end of the bulb. We may now call this the prime source of the Röntgen ray. The vertical ring shadows, however, indicate numerous secondary and more or less weak sources. A general statement can then be made to the effect that about the entire surface of the tube is sciagraphically active. The four plates were developed to-

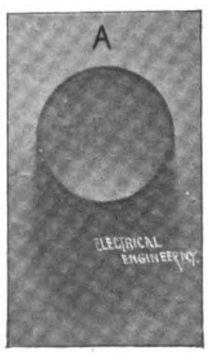

FIG. 4.

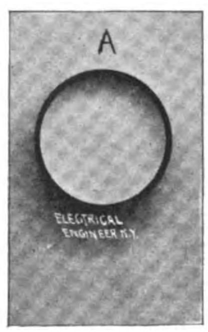

FIG. 5.

FIG. 6.

gether for an equal length of time. Plates 1 and 3 developed soonest, 4 a little slower, and the image on 2 was the last to appear. The resulting negatives are, however, all excellent and of about equal density. It is thus shown that a number of sciagraphs may be taken simultaneously if the entire tube be surrounded by plates. It might be added that the rings in Fig. 3 were held in concentric position with wedges of pine wood one-half inch thick, and since these do not show, they were entirely transparent for this length of exposure.

1. "Western Electrician", Mar. 7, p. 110 "Electrical Engineer", Mar. 11, p. 225.

The sciagraph shown in Fig. 3 is now, perhaps, the most interesting one of the series. It was purposely placed exactly opposite the anode. If the anode were the source of the ray, the resulting sciagraph would have resembled the one shown in Fig. 2; all the shadows would have been concentric rather than elliptical. The result plainly shows that the cathode, not the anode, is the source of the X-ray. The polarity was determined by testing the charges on the poles by means of an electroscope. In Fig. 5, plate 3, the shadow points only in one direction, and since the ring was near the anode, it would have shown a shadow on the opposite side had the anode been active. Fig. 4, plate 2, shows another striking result. The shadow is seen to broaden as it extends from the ring. This indicates that the rays crossed between the source and the object. The explanation is at once apparent. The rays were, in a sense, focused by the concave surface of the interior of the bulb, but it must not be concluded that the Röntgen ray has thus been actually focused.

If Figs. 3, 5 and 6 be carefully examined, the vertical shadows will be seen to be quite distinct, and Fig. 4 shows the same result less strongly marked. These phenomena are closely associated with the fluorescent appearance of the tube, which is decreasingly marked toward the space around the cathode.

The entire experiment here described has been carefully repeated, to avoid error. To summarize, it shows that there is but one marked source of the ray, that portion of the bulb opposite the cathode, and that the entire surface of the bulb is more or less a weak secondary source; that it is the cathode, and not the anode, which produces the rays. The only question which now remains is whether it is the interior or exterior of the tube that is active. There are many reasons which point to the interior surface. Another tube has just been designed to test this point. However, it would seem that the active surface would be that struck by the charged molecules. These experiments have been largely directed by the electrolytic theory of the production of the sciagraph which has been advanced by the writer.

The tube used in these tests was one especially designed to promote electrical exhaustion. The writer has advanced the opinion that this was accomplished by the occlusion of the gas by the anode. The vacuum of the tube was too low to produce the sciagraph when first tested, but after being excited for about ten hours became quite active. If, however, the current is reversed, the tube immediately fills with the purple light at first present. This seems quite conclusive evidence and further shows that no material particles are projected through the walls of the tube.

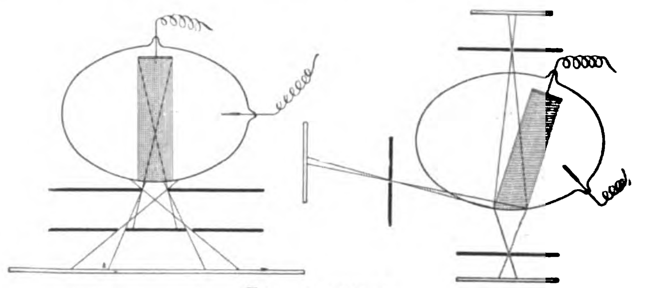
THE SOURCE OF THE X-RAY.

BY C. E. SCRIBNER AND F. R. M'BERTY.

IN an effort to locate the source of the X-ray in the Crookes' tube, the following experiment was made: Immediately beneath the bulb was placed a screen of lead, thick enough to be nearly opaque to X-rays, with a circular opening one inch in diameter immediately under the bombarded spot of the bulb; 2½ inches below this diaphragm was placed a second screen with two openings of one-half inch diameter, located so far apart that any ray passing directly from the cathode plate through the first aperture would be intercepted by the second screen. Below the second screen was placed a photographic plate. The arrangement is represented in Fig. 1.

A short exposure and developement of the plate brought out two densely black elliptical spots on the plate.

Referring to Fig.1, if the X-ray had proceeded from the cathode alone, in straight lines therefrom, no image would have been produced on the plate. The ray must have proceeded from some point in the tube far below the cathode to have reached the plate at all. The dimensions of the apparatus and the spots on the plate were accurately measured, and were plotted out to scale in the way frequently used in optics. Straight lines carried from the edges of the black spots at the edges of the screen, located the source of illumination at the wall of the bulb. Moreover, the illuminated spots on the plate showed strongly illuminated central discs surrounded by less sharply illuminated parts, such as might be expected



FIGS. 1 AND 5.

to be produced by a source of radiation of considerable area acting through such a system of screens.

This experiment seemed to demonstrate that the ray did not proceed from the cathode alone, unless it was diffused in all directions from the wall of the tube at the point of bombardment. It of course did not differentiate between rays actually proceeding from the glass, and rays which might proceed from matter in the same line within the bulb. In the same experiment a pin-hole image of the bombarded spot of the bulb was obtained through a very small hole in the second screen.

Immediately following this experiment, acting upon the hint obtained in it, a number of pin-hole images were taken of different bulbs, the upper screen being absent. In a pin-hole photograph any source of X-rays within the bulb, or on any portion of the wall of the bulb, would necessarily produce its image on the photographic plate below. In every case, however, the image on the plate was solely that of the fluorescent portions of the bombarded spot. The image corresponded in size, form and position with the utmost exactness to that which would be expected from the optical construction, on the assumption that the source of illumination was at the inner wall of the bulb. It was larger than the actual spot in the bulb when the distance from the wall of the bulb to the screen was less than that from the screen to the photographic plate, and smaller under the reverse condition.

No image was obtained in any case of any spot or object within the bulb other than the bombarded spot opposite the plate serving as cathode. The image did not even include the diffusely fluorescent yellowish streaks radiating from the bombarded spot or flickering about the walls of the bulb. Of course with a current which converted the two electrodes alternately into cathode and anode, two spots of bombardment would be obtained.

Figs. 2 and 3 represent two pin-hole photographs of different

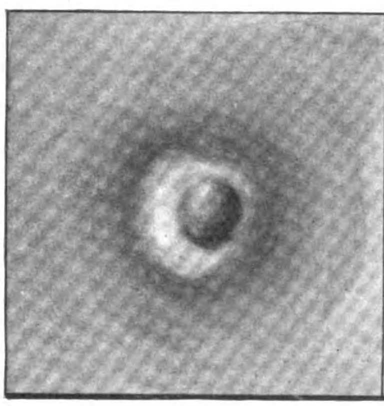


FIG. 2.

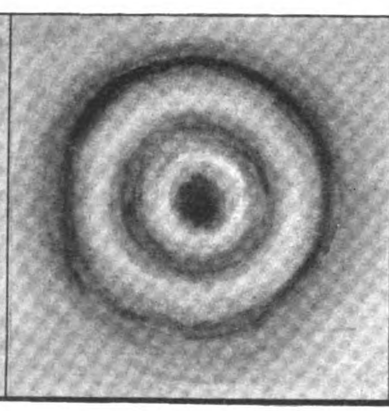

FIG. 3.

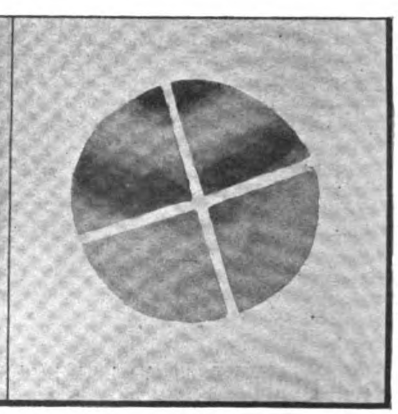

FIG 4.

bulbs. The bulb used in making Fig. 2 had a plain disc of aluminum as cathode. That used for Fig. 3 had a cathode made up of a central small disc of platinum surrounded by a ring of aluminum. The bright lines in the bombarded spot and in the images do not correspond to broad surfaces of the cathode, but to edges or raised portions. These figures are made from India-ink drawings copied from the negatives as faithfully as possible, on account of the unsatisfactory character of prints taken from the negatives themselves. The negatives of course present the shadings with greater delicacy and evenness, and the outlines more distinctly.

It will be remembered that Professor Röntgen, in his announcement of the discovery of the X-ray and its attendant phenomena, mentioned that when the stream of radiant matter is deflected by means of a magnet, the X-ray proceeds from the new spot of bombardment. This proposition of Professor Röntgen has been abundantly confirmed by means of the pin-hole photographs. Beneath the bulb the image of whose bombarded spot is represented in Fig. 3, was placed a diaphragm with a one inch aperture having a pair of lead cross wires extending over the aperture and crossing at its center. The point of crossing of these wires was located immediately under the center of the series of concentric rings which constitute the source of X-ray illumination in that bulb. Beneath the diaphragm carrying the cross wires was placed the usual diaphragm with a pin-hole aperture, and below that the photographic plate. When all was in readiness the stream of radiant matter, and consequently the spot of bombardment in the bulb, were deflected by means of a powerful electromagnet, so that the second bright ring crossed the center of the cross wires. After a long exposure the plate was developed; the image showed the shadow of the cross wires, and the rings which constituted the source of X-rays lying eccentrically upon them, the most strongly illuminated band—that which appeared blackest on the plate—crossing the center of the cross wires. The source of X-rays had been displaced to a different part of the bulb by the electromagnet, namely, to the new spot of bombardment. The image is shown in Fig. 4.

A similar experiment was made to determine whether the ray itself could be deflected. The magnet was placed to act upon the pencil of X-rays near the photographic plate, at such a distance that the action of the magnet did not produce any appreciable displacement of the stream of radiant matter, but that it would tend to produce a considerable displacement of the image upon the plate if the ray should be susceptible to its action. The plate was exposed with the magnet unexcited for twenty minutes, and then subsequently with the magnet excited for twenty-five minutes. If the image had been displaced by the magnet, two like images in different positions should be found upon the plate. As a matter of fact, but one was found, and that in position to indicate that the magnet was of no effect in displacing the pencil of rays outside the bulb.

The evidence of single pin-hole images of the different bulbs would seem to furnish sufficient grounds for the assertion that the X-ray proceeded only from the bombarded spot at the inner wall of the tube opposite the cathode. A further experiment was made, however, which is conclusive on this point. Three pin-hole images were taken simultaneously of the same bulb. One plate and diaphragm were arranged to view the bombarded spot from immediately below. Another plate and diaphragm were placed at the side of the bulb. A third plate and diaphragm were placed above the bulb, in position to look down directly upon the bombarded spot. A special bulb was made having its cathode placed in a somewhat oblique position so that the bombarded surface might be visible from a point in a line perpendicular to it outside the bulb, without obstruction by the cathode. The arrangement is represented in Fig. 5.

When these plates were developed after a long exposure, the lower plate was found to contain the usual image of the bombarded spot at the bottom of the bulb. The plate at the side contained an inverted side elevation of the same spot. The upper plate also contained an image of the bombarded spot at the bottom of the bulb. On none of the plates was there any other image whatever, although each plate was exposed to the whole bulb. The small spot at the bottom of the bulb at the point of bombardment, on the inner wall of the glass, was the only point about the bulb from which any X-rays proceeded.

The images also tended to show that the source of the ray was at the inner wall of the bulb. If it had been at the outer surface, there would have been no glass in the path of rays to the lower plate, and two thicknesses of glass in the path of those to the upper plate; hence the image on the former plate would have been much stronger than that on the latter. If the source were at the inner wall, equal thicknesses of glass would be in the paths of rays to the two plates. The images were of such depth of shading as to show that the plates had been equally illuminated, allowing for the difference in distances between the spot and the plates. No more definite experiment than this seems possible.

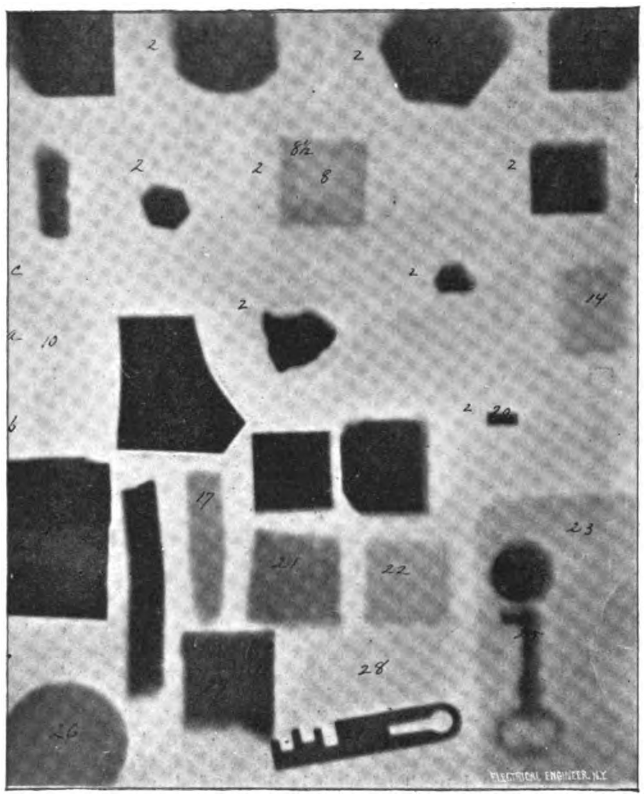
These pin-hole photographs were made at different times between February 20 and March 15, the first described experiment having been made at the earlier date, the last described demonstration about the latter date; the experiments were reported at a meeting of the Western Branch of the American Institute of Electrical Engineers on March 25.

From all knowledge which we have been able to gain of the numerous experiments with X-rays, we believe these experiments were the first to locate the source of the X-ray; as respects at least the large number of tubes which we have used, they located the source accurately and conclusively. So far as we can learn also, no other pin-hole images of bulbs have been taken, excepting perhaps the one which Professor Röntgen thought he had obtained. This mode of photographing promises excellent results in investigations as to the relation of the X-rays to the cathode discharge.

AN X-RAY PHOTOGRAPH OF VARIOUS SUBSTANCES.

We have received from Professor N. M. Terry, of the Physical Laboratory at the United States Naval Academy, Annapolis, a photograph taken by means of the X-rays, which we reproduce in the accompanying engraving. The number and variety of the substances embraced in it form an excellent means of comparison. The photograph was obtained by an exposure of 30 minutes with a Carbutt plate (26), with a pasteboard cover between the plate and the objects. The numbers designate the following substances:

1. Rock salt, 0.6 inch thick. 2. Cork, 0.4 inch thick. 3. Quartz, 0.45 inch thick, cut parallel to optic axis. 4. Verre trempe, 0.4



Roentgen Ray Photograph by Prof. N. M. Terry.

inch thick. 5. Glass, 0.7 inch thick. 6. Chalk. 7. Iceland spar. 8. Mica, very thin. 9. Quartz, over a square piece of glass. 10. Aluminum foil; (a) four thicknesses, (b) two thicknesses, (c) one thickness. 11. Platinum foil. 12. Tourmaline. 13. Aragonite. 14. Paraffine, 0.4 inch thick. 15. Tinfoil; (a) one thickness, (b) two thicknesses, (c) three thicknesses. 16. Rubber insulated wire. 17. Electric light carbon. 18. Glass, 0.32 inch thick. 18. Alum, 1.4 inch thick. 20. Tourmaline. 21. Gas coal. 22. Bee's wax. 23. Pocketbook, 10 thicknesses of leather. 24. Coin in the pocketbook. 25. Key in the pocketbook. 26. Machine oil in ebonite cup. 27. Ebonite, 0.25 inch thick. Other samples have given very faint shadows like wood and leather. This was polished. 28. Wood, 0.2 inch thick. 29. Steel key.

PLAIN IRON CONDUIT.

BY A. E. DOBBS.

WHY cannot plain iron pipe be used in a conduit system? Are the insurance men afraid that it may be burnt out? A half-inch iron pipe would surely have as much carrying capacity as any two wires that could be drawn into it, and in case of trouble on account of being confined in such a small

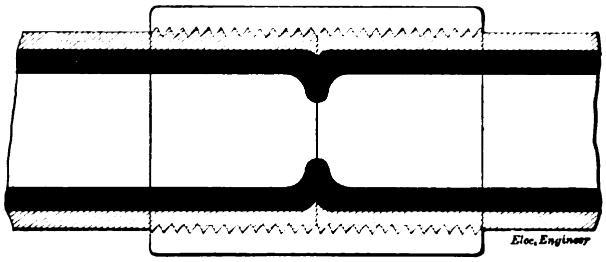


FIG. 1.

space, the low resistance of the arc should be able to melt them down without doing the pipe any serious injury.

A reamer pushed through the pipe would remove all fins, and burrs could easily be removed from the ends. By dipping it in hot asphaltum the tendency to sweating would be removed. The conduit people surely have to ream out their pipes, and if a contractor should demand a smooth asphaltum-coated pipe it would surprise him to find how many firms could furnish it to him at short notice.

But then there is the thought of a possible careless workman. But can one name a business that does not possess that class? Responsible contractors generally have foremen who are familiar with their methods and wishes, and to whom they can entrust the supervision of their work. Occasionally a projection may cut the insulation of the wire, but so also does iron armored conduit if the ends are not carefully reamed, as shown in Fig. 1, which is no fancy sketch. Every wireman knows that under these conditions a certain pitch or angle of these raised ends will strip the insulation like a knife. Of course Fig. 1 is an example of careless work, but iron armored conduit is not condemned on that account.

The rules of the National Board of Fire Underwriters seem to be a little inconsistent on this point. They first state that "The object of a tube or conduit is to facilitate the insertion or

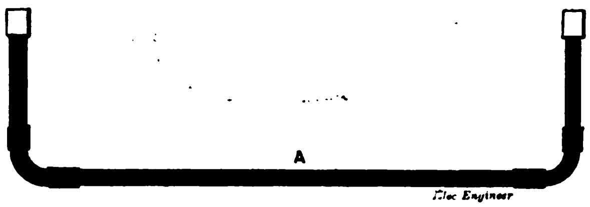

FIG. 2.

extraction of the conductors, to protect them from mechanical injury, and, as far as possible, from moisture. Tubes or conduits are to be considered merely as raceways, and are not to be relied upon for insulation between wire and wire, or between the wire and the ground." This is admirable, but in the rules that follow, conduits seem to be regarded especially as to their insulating qualities, and an insulation of one megohm for each ten-foot length of pipe is demanded, and in treating of other kinds of conduit, their insulating qualities seem to be referred to instead of their raceway function.

Suppose again, as in Fig. 2, which shows a pipe running from wall to wall under the flooring, which is often the case, that water should get into the pipe, and, of course, settle at A, which has happened more than once. In a plain iron pipe, as the room gets warmed up, the water would evaporate and leave the wire dry, while the paper tube used in iron armored work swells, gets pulpy, and in cool spots remains so for weeks. Another thing about iron armored conduits not considered by inspectors, but an important consideration with contractors, is its bulky size. Figs. 3 and 4 show the difference between a ⅝-inch armored and a plain conduit. It will be seen that the armored conduit is more expensive on account of its larger size, the labor required in putting it in place, and in many places the wall has to be channeled, where the smaller pipe has to be plastered in. In order to economize, the contractor uses pipe of the smallest possible diameter, often using a ⅝-inch pipe where a ½-inch should be, and duplex wire with a very thin covering, in fact, so thin that the insulation between wires cannot be very high.

Now, it seems strange that insulation in the wires should be sacrificed to secure insulation in the pipe itself, though it has always seemed absurd that insurance men should be so careful to secure insulation in conduits and at the same time insist on the best rubber covering for the wire. This is on a par with their requirements as to concealed work. Here the wire must be kept away from the woodwork and be carried upon porcelain insulators and cross joists through porcelain tubes so that bare wire would still be safe; but must at the same time have the best of insulation on the outside. When a man engaged in railroad work, for example, used to seeing wires no better than those used in house wiring—and having 500 volts difference between them—thrown around in bunches upon the floor of the car under the seat, crossing iron braces and crossing underneath the car in bunches of four or five, exposed to mud and slush, with only a thin cotton hose for protection, he is apt to wonder at the restrictions thrown around house wiring. But of course car wiring is readily accessible and is subject to constant inspection; but it gives so very little trouble that the wiring in most cars is not disturbed for years, except at the ends, when controllers or motors have to be repaired.

Things like these excite in the practical man somethink like disgust at the rules formulated by experts, but then, of course, house wiring contractors of the baser sort have to be closely watched, and the long list of rules was not provoked by the

FIGS. 3 AND 4.

work of reputable contractors. From the expert's point of view, the best is none too good, but from the contractor's point of view we must adapt our work to the financial resources or inclinations of our patrons, and it is notorious that each new set of rules means decreasing profits. The time when the electrical contractor was looked upon as the peer of the opulent plumber or coal baron has gone by. Insurance men would like to have nothing but fireproof buildings erected, but the financial limitations or inclinations of the people have led to the putting up of wooden buildings all over the country.

Underwriters should, and I believe are, trying to make wiring methods as simple and accessible as possible, and I believe that under proper restrictions they would find plain iron pipe a help in that work, for the reason that a great deal more conduit work would then be used than at present, and I believe plain iron pipe would be a better protection for the wires than some of the conduit tubes now on the market.

For wooden buildings I would propose that ordinary circuit breaker buttons should be stapled to the side of the joists and wire pulled through them (Fig. 5) and in going through the joists or studding, short porcelain bushings, not smaller than ⅝-inch on the inside, or a flexible tubing fastened between the lath; two or three turns of tape will hold it up tight enough at the outlets; the wire does not need to be drawn taut. Such a circuit can be pulled out for inspection or repairs at any time and is cheaper than conduit. The Seely insulator (Fig.

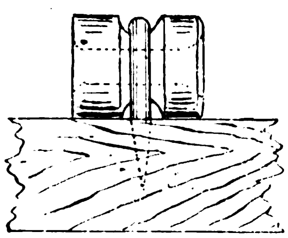

FIG. 5.

FIG. 6.

6), has lately, in accordance with a previous suggestion ("The Electrical Engineer," Aug. 7, 1895, p. 128), been covered with a silicate glazing and would doubtless be approved by the inspector.

The restrictions I would throw around plain iron conduit would be: 1. That the interior should be perfectly smooth. 2.

That all burrs at the end should be reamed smooth also. 3. That the interior should be given a coating of asphaltum paint. 4. That wires should be of the standard prescribed by rules 12 and 18, which provides that wires "must be solid at least 3-64 of an inch in thickness" and covered with "substantial braid," etc. Duplex wires in this conduit should be forbidden, as experience has shown that they are more liable to make trouble than two single wires drawn in together. 5. That no pipe smaller than ½ inch inside diameter be allowed; this would remove the temptation to use wire with thin insulation.

This article was not written for the purpose of finding fault with iron armored conduit—which is the best thing now on the market—but for the purpose of enabling contractors to make some money on their work. While prices of material are falling all the time, electric work seems to be getting more expensive and less remunerative. Many men who have made a study of this subject feel that the business of house wiring is not yet standardized and that present rules and methods are only temporary. We may yet hope for concentric wiring, but that subject demands another paper.

APPARATUS OF THE ROYAL ELECTRIC COMPANY OF PEORIA, ILL.

One of the electrical manufacturing companies which have more than held their own, are the Royal Electric Company, of Peoria, Ill. This company, conducted on a very conservative financial basis, have weathered these several years of financial stringency and hard times in a comparatively easy way, and have done a very comfortable business.

Their apparatus, for which there has been a steadily increasing demand, offers special features and advantages, which are the cause of the perfect satisfaction they give wherever used. We refer in particular to their alternating current system, which has stood the test of time in practical use.

The alternator, which is shown in its complete state in Fig. 1, is of the inductor type. It is mounted on a solid frame with proper provisions for tightening belts. The ample bearings are of the self-oiling type, and are provided with oil gauges. The exciter terminals, as well as the high potential current terminals, are shown mounted centrally on top of the machine. To the right, we find the driving pulley for the alternator; to the left, that for the exciter. The construction of the field magnet is specially noteworthy. It consists of a tube, Fig. 2, surrounded by a single field magnet spool. The latter is attached to the frame work, and is stationary. Around the spool is located the spider on which the laminated core pieces constituting the armature core, are mounted. Four projections of the spider are visible in the view shown; they are extensions to which the central tube and the field magnet coil are secured by means of screws. The others are covered by the laminations of the armature iron. At the two extreme ends of these laminated blocks, are mounted two sets of coils which constitute the armature winding.

The coils on each side are generally connected in series, and each produces in the standard machine 1,000 to 1,100 volts. Connecting all the coils on both sides in series will evidently make the machine a 2,000-volt machine; on the other hand, a subdivision of the coils will enable the same machine, without change of coils, to be reduced to 500 volts, 220 or 110 volts for low tension alternating current work, without the use of transformers. Owing to the position of these coils at a place where they do not interfere with the rotary parts, or increase in any way the magnetic circuit, it is evident that plenty of space can be used for properly insulating the coils. This has been taken advantage of in this machine, and in utilizing it for high tension work no step-up transformers are recommended with the machines, not unless the potential rises above 5,000 volts. This construction of field coils and their position offers a great many advantages; and in case a coil should be damaged by accident or lightning, it will be readily seen that the injured coil can be cut out without difficulty and be replaced in a very short time. As they are not inclosed, they are capable of quickly radiating the heat produced in them, and are therefore capable of keeping considerably cooler than similar windings, carrying the same amount of current in other designs.

Heretofore it has been customary to have a separate armature on hand with nearly every machine, but the Royal Electric Company supply an extra coil or two with a new machine, which has proved to be all that is necessary as a safeguard. The cross section of the armature coils is so calculated that the energy wasted in them is a very small percentage, and close regulation is insured.

The rotating part of the machine consists of a central wrought iron core part, with two end plates which have the shape of a star, in such a way that alternate coils are covered by them. Intermediate spaces are blocked to prevent unnecessary air grounds.

Tests made on these machines disclose that the excitation required for them is lower than that of ordinary alternators, and that the energy is about one per cent. of the output of the machine, and in some cases less. This type of machine is primarily an alternator, but it has this further advantage that the circuits of the two sides can be operated independently from one another, and can be arranged to produce two separate currents whose phases are 90 degrees apart. Central station owners would have, therefore, the advantage of not requiring a new machine, should they desire to put two-phase motors in the circuits of the machine. In most types this cannot be accomplisheu. These machines are thus far built up to 2,000 lamp capacity, and larger sizes are in the course of construction.

Besides the various accessories which make a system complete, and which are carefully worked out by the company, we wish to mention their transformer, which also has certain points of merit and advantage. It goes without saying that a transformer nowadays should be efficient, close regulating and have but small internal losses. These are features which are claimed by the transformer of the company. In the latest form shown in Fig. 3, they provide special means for protecting the transformer, as well as the lineman, by primary fuses

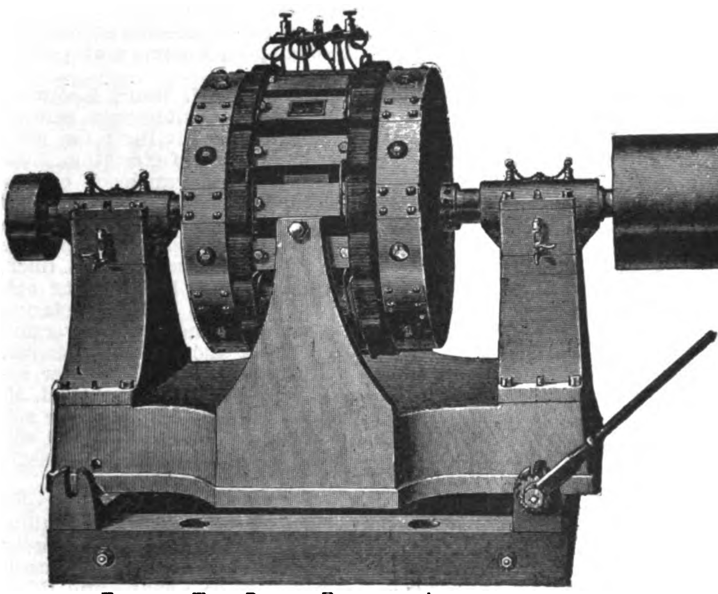

Fig. 1.—The Royal Electric Alternator.

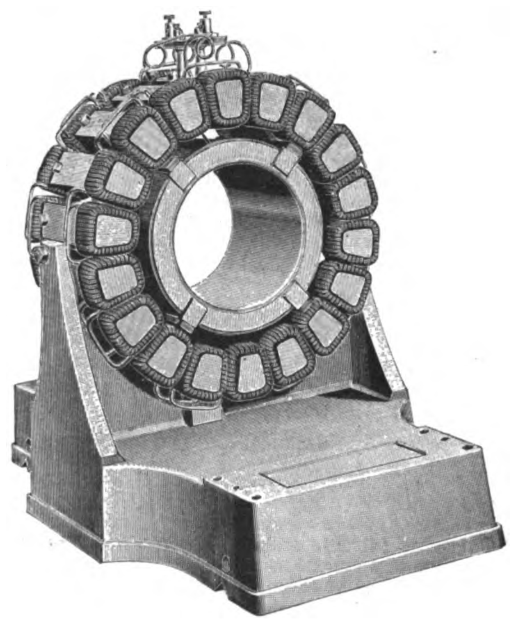

Fig. 2.—Royal Electric Alternator.

which are covered by a spherical shaped projection, visible on the face of the transformer box. They extend from the front to the back. These fuses are mounted on cylindrical plugs which are provided with insulating handles projecting outside of the case. They are protected in a weather-proof manner by the spherical shaped cover just mentioned. These two hollow shells form a single casting, and are held in position by a centrally placed thumb-screw, which, when released, gives access to the fuse plugs; but the thumb-screw is so constructed that it is impossible to remove the shells bodily from the casing. In all the various details of construction, special care is

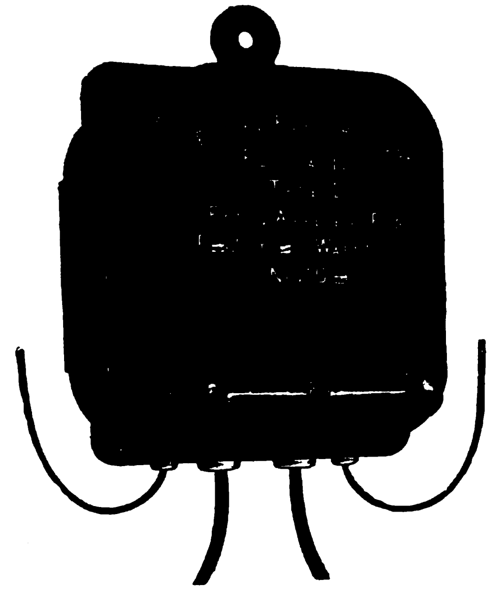

FIG. 3. ROYAL ELECTRIC CONVERTER.

taken to guard against danger, and to provide proper means for protection and insulation.

With the careful management on the commercial end of the business, as well as the pains taken for safety and stability of construction in the manufacturing end, we have no doubt that this company will do a rapidly increasing business. The officers of the Royal Electric Co. are: Ferd. Luthy, president; E. B. Hillman, vice-president; G. T. Page, secretary and treasurer; G. Luthy, manager; G. G. Luthy, assistant manager.

AN ANALYTICAL STUDY OF THE ALTERNATING-CURRENT ARC.[1]

THE first part of the paper consists of an analytical study of the distribution of light throughout the various radiating regions in the arc when supplied with electric power of known constant amount, the periodic variations of the current through the arc and of the potential difference between the carbons being at the same time recorded. The power was measured by means of a bifilar wattmeter, while by means of a series of mirrors and a rotating disc carried by a synchronizing alternate-current motor, the mean value of the light taken from any part of the arc was compared with the instantaneous value of the light taken from the same part of the arc, and taken at any assigned instant during the period. Thus the arc itself was its own standard, and difficulties due to slow variations in the mean light of the arc disappear. The facts observed may be summed up as follows: The purple light of the true arc undergoes a periodic variation, and, as far as the eye can judge, is completely extinguished during a certain interval during the phase; it has equal maxima values during the period, at instants slightly lagging behind the instants of maximum power expenditure in the arc. On the other hand, the illuminative power of the carbon crater varies between a minimum value and two unequal maxima, the greater maximum occurring when the carbon is positive, and at an instant slightly lagging behind the instant of maximum power expenditure in the arc. The second part of the paper consists of a comparison of the efficiency of the alternate-current arc regarded as a light-giving agent as compared with that of a continuous-current arc taking the same mean power. Using two arcs, which may be regarded as typical of those used in practice, the mean spherical candle-power was compared for equal expenditure of power in the arcs, and it was found that for the alternating-current arc employed, the total mean spherical candle-power was always less than that of the continuous-current arc. Lowering the frequency seems to decrease the efficiency of the alternating-current arc.

[1] Abstract of a paper read before the London Physical Society by Prof. J. A. Fleming and Mr. Petavel.

X-RAY EXPERIMENTS.

THE "Comptes Rendus" continues to present the result of the work of a number of French experimenters on the X-rays. In its issue of March 2 M. D'Arsonval describes experiments, which he sums up as follows: "All bodies giving rise to greenish-yellow fluorescent radiation can impress photographic plates through opaque bodies. It follows that the rôle of cathode rays in Röntgen's experiments would appear to be limited to fluorescing the special kind of glass of which the Crookes tubes are composed." M. Henri Becquerel in the same number refers to his previous brief announcement of experiments, showing the existence of invisible radiation emitted by certain phosphorescent substances and passing through bodies opaque to light. Such radiation is emitted by strips of the double sulphate of uranyl and potassium. MM. A. Imbert and H. Bertin-Sans make a communication on "The Diffusion of Röntgen Rays." They find that within the limits of their experiments Röntgen rays are regularly reflected to only a very slight extent; on the other hand, they may be much diffused, and the "intensity of the diffusion appears to depend much more on the nature than on the degree of polish of the diffusing body. A fact which tends to show that the new rays have a very small wave length such that it is impossible for us to attain the degree of polish necessary to cause regular reflections. The clichés obtained by us reveal, moreover, in quartz and cork different degrees of transparency in regard to the rays diffused by the different bodies used." MM. Bleunard and Labesse have a note on "The Passage of Röntgen Rays through Liquids." They state that water is very transparent, and, as has been previously observed, they find that color has no perceptible influence. Solutions of bromide of potassium, chloride of antimony, bichromate of potash, offer "a somewhat considerable resistance to the passage of Röntgen rays." Solutions of borate of soda, permanganate of potash, are less resistant.

In the "Comptes Rendus" for March 9, M. Henri Becquerel describes further experiments with the invisible rays emitted by phosphorescent bodies, which do not emit light for more than about 1-100th of a second after cessation of excitation. Electrified bodies are discharged. Using an Hurmuzescu electroscope, which, protected against electrical influence by a metal case and against ultra-violet light by yellow glass, can retain its charge for months, M. Becquerel found that on replacing some of the yellow glass by a strip of aluminum 0.12 mm. thick, and applying a strip of the phosphorescent body to the outside, a charge was dissipated in 2 hours 56 minutes; placing the phosphorescent body inside the case under the divergent gold leaves naturally resulted in their more rapid collapse. Experimenting with a view to discover how long after exposure to light these invisible rays continue to be emitted, M. Becquerel finds that with sesquioxide of uranium, double sulphate of uranyl and potassium, sulphate of sodium, and sulphate of ammonium, the power of the rays emitted is not sensibly diminished after 160 hours in the dark.

Amongst the many communications to the Académie des Sciences there is one dated Liège, Feb. 13, 1896, emanating from a M. de Heen, which commences as follows: "In order to take date, I have the honor of informing you that according to my latest experiments the X-rays of Lenard and Röntgen do not emanate from the cathode, but from the anode." Another communication of interest is one from M. G. H. Niewenglowski, in which he states that he has discovered that phosphorescent bodies have the same property of assisting the transmission of solar light as phosphorescent sulphide of zinc has in regard to Röntgen rays, a phenomenon which was recently pointed out by M. Chas. Henry. MM. Abbé Buguet and Albert Gascard, in a note in the "Comptes Rendus" of Feb. 21, state that the natural diamond is far more transparent to X-rays than the imitation variety, and the same holds good for natural jet. In the same issue MM. Darieux and de Rochas briefly describe some experiments made with the eyes of freshly-killed pigs, which go to show that the media of the eye, so perfectly transparent to light, are but very slightly so to X-rays.

ONE MORE UNFORTUNATE.

The electric light and water plant of Le Mars, Ia., will be sold April 15 to satisfy bonds of $23,290. The plant is valued at $150,000 and will be sold without redemption.

HIGH-VOLTAGE LAMPS AND THEIR INFLUENCE ON CENTRAL-STATION PRACTICE.[1]—I.

BY G. L. ADDENBROOKE M. I. E. E.

In the spring of 1891, which was the last occasion when the alternating vs. continuous current controversy came prominently before this institution, and when Mr. Crompton brought forward his feeder argument, I had the honor of opening the discussion, and subsequently continued the argument in the technical press, besides going into it privately with Mr. Crompton. I was not, however, convinced of the superiority of low-pressure direct supply, and on the old premises I remain unconvinced still; but I saw that the advantages of the two systems were in many cases very nearly balanced, and if one or other was ultimately to prevail it would probably be for some other reason than lay in the arguments which had so far been brought prominently forward on either side. It was, in my mind, useless to say that the two systems were each the best for certain situations, for how was the line to be drawn; or in some cases were we to have both systems in one town? Though a possible, this did not seem to me a desirable solution. The question is not merely an academic one. Hundreds of thousands of pounds are yearly now spent on electric lighting, and that a large portion of this sum should be spent in a way that is not the best and most permanent is a serious matter. Besides this, as a consulting engineer, I found my position an unpleasant one. What was I to recommend to my clients; and if I halted between two opinions, what would my clients think of me? I regret that in these matters I have not the assurance of some gentlemen, who, I understand, circularize all town councils, keep their own touts, and are prepared to give cut and dried verdicts without hesitation on engineering points which, I must confess, I approach with a certain amount of awe and misgiving, and a very serious sense of responsibility. Now, it struck me four years ago, as I daresay it did others, that as the two methods had been argued over so carefully without any definite conclusion being arrived at, probably some outside and fortuitous circumstance which neither side had taken account of would ultimately turn the balance one way or the other.

Possible Sources of Influence on Central-Station Practice.—I therefore made a careful survey of the field, and the only eventualities I could think of, or which seemed likely to have a very important bearing on the problem, were the following, viz., the introduction of (1) an altogether new form of lamp, (2) a cheaper material for mains than copper, (3) a high-voltage incandescent lamp, (4) a much more economical incandescent lamp of the present voltage, (5) an improved and much cheaper storage battery.

Respecting a new form of lamp: After having seen Tesla's experiments at the Royal Institution, and after having learnt privately the views of some of our leading investigators on the field which they opened, I must say, as a practical man, I did not see any immediate hope of a commercial success in this direction, however interesting the results might be scientifically. As regards the chance of a cheaper conductor being forthcoming, I have dealt with this question at length in a recent article in the London "Electrical Review." Owing to the cheap rate at which aluminum can be produced, and will increasingly be produced in the future, and since the conductivity of aluminum is 56 per cent. of that of pure copper of the same section, the chances of aluminum ultimately supplanting copper are strong, but the change will undoubtedly be a comparatively slow one. The possibility of this, however, points to a reduction in the price of conductors; and this, of course, would tell somewhat in favor of moderate pressures. Again, as even in moderate-pressure mains insulated with bitumen or other compounds the cost of insulating is twice the cost of the conductor itself in the sizes usually employed, it is quite conceivable that very important economies may be effected in this direction. It is obvious that improvements of this character would probably tell more in favor of moderate pressure than of high.

Having thus disposed of the conductor question, we come to the third and fourth alternatives I have mentioned as likely to influence central-station practice, viz., the introduction of a lamp of higher voltage, or a more economical lamp of the present current voltage. When thinking over the matter in 1891, I saw that, as fairly good lamps of 8 c. p. for 100-volt and 110-volt circuits were being made, two of them could be put in series, and that we should get very simply a 16-c. p. lamp of 200 to 220 volts. This, however, involved giving up 8-candle lamps except two in series, which, as the charge for current was then usually 8d. per unit, was a serious matter; and again, as there were two filaments in each lamp, the breaking of either of which would spoil the lamp, this also introduced an important objection, particularly as the Ediswan monopoly maintained the price of lamps at 3s. 6d. for ordinary voltages, and could hardly be expected to supply lamps which would be more expensive to make, except at an enhanced price. The prospect of obtaining high-voltage lamps did not, therefore, at that time appear bright. Time has, however, brought about great changes in the lamp industry, due largely to the expiry of patents, which quickly led to numbers of good lamps being placed on the market at less than one-third the price formerly charged, and at the same time brought active and pushing competitors into the field. Two years and a half ago, finding some disposition abroad to adopt higher voltages, I drafted an article pointing out the enormous gain which would accrue in the distributing system if higher voltage lamps were adopted, intending to send it to one of the journals. The question, however, then appeared somewhat problematical, and other business led to the article being put on one side. I did not, however, forget the matter, and last December year, finding that one or two firms were trying to introduce lamps of 200 volts, I looked over my draft again, and, having somewhat elaborated it, sent it to the London "Electrical Review." The article attracted the attention of Mr. Baynes, then of Bradford, and he wrote detailing his experience and the experiments he had made with high voltage. Since then the matter has advanced by leaps and bounds. Several lampmakers are undertaking to supply 16-c. p. lamps of voltages up to 230 and even above; and not only this, but Mr. Stearn and one or two other makers are offering lamps up to this voltage of 8 c. p. also, and guaranteeing a fair economy. The lamps are also being offered at moderate prices. Low-tension central-station engineers have not been slow to perceive the facilities these lamps offer. In some cases they have been adopted publicly, and in other cases private experiments are being made on them with satisfactory results. I also hear from those manufacturers who are catering for the market that the demand for high-voltage lamps is steadily and rapidly increasing. The adoption of these lamps is, of course, somewhat in the tentative stage, but so much progress has been made, and the results attained so far are so good, that no one can doubt that in a year or two they will become a permanent institution. It may also be noted here that since this paper was sent in I see that Professor Kennedy has considered the 230-volt lamp sufficiently sound to recommend the Town Council of Edinburgh to adopt it.

[1] Paper read before the London Institution of Electrical Engineers, Feb. 27.

FLAX STRAW AS FUEL AT WATERTOWN, S. D.

With regard to the use of flax straw as fuel in the electric light plant at Watertown, S. D., Mr. H. V. Peterson, manager of the electric light works, writes us:

"Our location here, so far from the coal fields of Iowa and Illinois, results in transportation charges being so great as to prohibit the use of coal in this business with profit. Soft coal will cost from $3.50 to $6.50 per ton on cars here for the various qualities, from Iowa slack to the high-grade Eastern coals; and wood ranges from $3 per cord for soft wood to $4 for hard on cars. We can buy flax straw in abundance delivered at the plant for $1 per ton, and consider that two tons of straw is equivalent to a ton of the best coal. We have no especial arrangement for using the straw. The same furnace and boiler are in service, as when burning any other fuel, only that we have constructed sheet iron chutes to the furnace doors with flaring approaches. By keeping the chutes full of straw and gradually working it into the furnace as consumed, we avoid the necessity of constantly opening and closing the furnace doors. The straw is delivered to us loose and burned in that same condition. It, of course, requires pretty close attention, yet, after all, does not burn away as rapidly as one would suppose. The fiber in the straw makes an intense heat."

THE PENETRATING QUALITIES OF THE ARC LIGHT.

In the first number of the "Photographische Rundschau" for 1896, Herr Schmidt, of Munich, describes some experiments he made about a year ago with regard to the penetrating quality of the arc light. He found that the light from an arc lamp passes more easily through certain substances than sunlight. A wooden board 2 mm. thick was placed before a photographic plate, and an exposure of only 10 sec. to 12 sec. sufficed to attack the plate. India-rubber, bone and ebonite proved less transparent, with a thickness of 2 mm., an exposure of half an hour was required to cause the same effect as through wood. Celluloid was found, however, nearly opaque. A 43-ampere continuous-current arc lamp was employed, the photographic plate being placed about 16 inches from it.

CONTENTS.

EUROPEAN ELECTRIC RAILWAY STATISTICS.

THE marvellous rapidity with which electric traction was adopted in the United States could not but have its influence on the city passenger traffic of other countries, but it has taken practically ten years to convince Europe that the horse could no longer compete for dividends with the trolley. But now that our friends across the ocean have become convinced of that fact, it would seem as if they were on the road to match our own record in time, as shown by the excellent table of statistics compiled by our contemporary, "L'Industrie Electrique." The accompanying tables,, which show the number and character of the roads now in operation in Europe, indicate very clearly the trend of electric railroading abroad. The trolley, of course, far outnumbers all other systems. Of the others, we may ignore practically those roads with central rail, as they are mostly of short length, where placed on the surface; or they are so situated that they are rendered inaccessible to the publis, such as in the City and South London tunnel, or on the Liverpool elevated railway. But the eight accumulator roads in Europe, representing an increase of four during the year, are more significant. The largest system of this type comprises three roads in Paris, operating 19 storage battery cars, some of which have been doing duty since 1892, and the addition of the third road last May seems to indicate that for the conditions there existing the storage car has proved satisfactory. We would also draw attention to the Hague-Scheveningen road, in Holland, which

Countries.	Length of track, Kilometres.	Power in K.W.	No. of Motor Cars.
Germany	406.4	7,194	857

Total	91	3	9	8	111

has been in operation since 1890, and is now operating 14 motor cars and 2 trailers. Considering the popularity of the storage battery for stationary purposes abroad, it is somewhat disappointing to find but three or four roads which have adopted them in the stations as load equalizers, but that this will follow in due course of time we have not the slightest doubt. Conduit roads still seem to lag, but, when their cost is considered, this ought to excite little comment. Indeed, in spite of the slow progress in this direction in the past, even in the United States, we believe that there will be much work of this character done in the near future. The conduit roads in New York, Washington and elsewhere will soon determine the practicability of this type of road, and we have no fear for the final outcome. A glance at the above tables brings out in strong relief the enterprise of Germany in electric railroading, in which her record is well abreast, if not ahead, of that of her electric lighting work. The Germans, indeed, may well be called the Yankees of Europe in electrical matters, and her neighbors on the Continent, as well as across the Channel, ought to profit by her example. Perhaps a glance at our own street railway statistics may act as a further stimulus, and hence we give the record below, which is as nearly correct as it can be obtained, considering the enormous extent of the industry:

Length of track, electric roads..........miles	10,363
Length of track, horse roads............miles	1,914
Length of track, cable roads............miles	632
Length of track, miscellaneous roads.....miles	679
Number of cars, electric	24,745
Number of roads, electric....................	976

In Pittsburgh a cable plant that has cost over $10,000,000 is about to be ripped out to make way for electricity. It is really a pity not to have used the cable trough for a conduit system; but, probably the roadbed had deteriorated too much to allow of such a thing being done. The incident shows, however, the way things are tending in America.

BUSINESS CONDITIONS.

BRADSTREET'S review of trade for the first three months shows that the number of business failures in the United States was greater than ever before in any such period, being 4,512, or 700 more than the dismal first quarter of 1895. The increase lay largely in the Western States and in New York City, and it is attributed to an undue extension of credits because of the assumed prospects of general improvement in business. To us it seems to be due to foolish war alarms and the fear of a dishonest system of currency. But for these conditions, we believe trade would have been much better. Even now, we look for steady, if slight gains, but nothing marked in the way of recovery appears possible until after election. The effect of an average Presidential campaign is perhaps equal in its bearing on business to that of a "small war," and fewer elections would be a decided gain.

There are obviously exceptions to the general drift. While it is satisfactory to know that the recent dullness in electrical industries is only normal as compared with what exists in other branches, it is evident when we look at the activity in the bicycle trade, that in some lines a good business can often be done when prospects on the whole are bad. We look upon the coming National Electrical Exposition as a hopeful and legitimate means of stimulating a slack demand. It will be full of things old and new that the public know little about but ought to buy; and if attention is thus drawn to them the chances of increased sales are infinitely larger than if nothing were attempted. For this reason, the success of the exposition is a common cause to which all should gladly lend their best efforts.

MR. EDISON ON THE X-RAY AS A SOUND PHENOMENON.

MANY have been the hypotheses put forward to account for the action of the Röntgen ray, but the most startling thus far is that which Mr. Edison brings out in his remarkable contribution to our columns in this issue. One is bound to look askance at the proposition that the X-ray is a phenomenon due to sound vibrations whatever be their order of amplitude, but Mr. Edison bases his opinion on some experiments as well as on some of the heretofore unexplained actions of the vacuum tube as a source of the X-rays. While Mr. Edison is well aware of the arguments which may be brought to bear against his "sound" hypothesis, there is no doubt that some observed actions of the X-ray are readily explained on that assumption; and, as a hypothesis, pure and simple, it is certainly worthy of note. With the great inventor's fertility of experiment and the facilities at his command, we may soon expect further facts in support of his views.

We print this week also a number of additional contributions on the subject, three of which are devoted to the source of the X-rays. Opinion still differs on this point. But the accumulated evidence seems to tend strongly to the confirmation of Professor Röntgen's original observation that neither the cathode nor the anode, but the fluorescent spot on the glass is the source of the X-ray. The very beautiful pin-hole experiments of Messrs. Scribner and McBerty would appear to add strong weight to the previous evidence on this point, as does also the novel method employed by Professor Stine. An interesting line of investigation has also been taken up by Mr. E. P. Thompson in order to determine whether phosphorescence produced by means other than electrical bombardment acts as a source of X-rays. The results thus far have been negative, but it is to be hoped and expected that further work in this direction may be carried on.

WHISKERED MESSENGER BOYS.

THE American District Messenger Company, of this city, is a progressive concern, and some of its plans must meet with instant approval. Such, for example, is the intention to have a bicycle corps which will operate all over the region lying in the uptown section of the city. To be able to summon brisk Ariels of this kind will be a decided boon, and will do much to place the district messenger system again on terms of equality with the telephone, while there will still be the advantage of being able to transport objects of bulk.

But when we turn to the proposition that all messengers must be close shaven, we hesitate. Of course everybody knows that for a long time past the district messenger "boys," like those one employs in the tropics to hold a horse or perform personal service, may be of any age, so that it is no shock to learn that many of them are fathers of families. But why should they be put to the expense and indignity of shaving, if their years are no drawback? It would be better to drop them from the employ, for certainly the possession or lack of whiskers is no criterion of efficiency. We would venture to suggest that very often messengers of a ripe age are preferable, hirsute or otherwise, and that it might be well to organize the older "boys," say from 25 up to 150 years old, into a commissionaire corps, after the useful English fashion.

TELEPHONY AND TELEGRAPHY.

ANNUAL REPORT OF THE AMERICAN BELL TELEPHONE COMPANY.

THE annual meeting of the American Bell Telephone Co. was held last week. The annual exhibit for year ending Dec. 31 compares as follows:

	1895.	1894.	1893.	1892.
Gross	$ 5,124,952	$4,848,244	$5,781,076	$5,100,886
Expenses	1,911,193	1,724,459	1,855,591	1,689,211
Net	3,213,759	3,123,785	3,925,485	3,411,674
Regular divs.	2,502,453	2,400,000	2,214,156	1,927,227
Extra divs.	630,000	600,000	1,125,000	991,863
Total surplus	2,151,011	2,151,011	2,151,011	2,151,011

The directors recommended that stockholders vote an increase of 10 per cent. in the share capital. The ticket makes no change in the directory.

The last year has been one of unprecedented growth in the output of instruments, in the number of exchange subscribers, and in the mileage of wire, whether used for exchange purposes or for toll lines. The number of telephones outstanding on the 20th day of December, 1895, exceeded the number outstanding on Dec. 20, 1894, by 92,470, much more than twice the gain in any previous year, and about three times the average yearly gain.

This stood, too, for an increase in the number of subscribers of 38,263 on Jan. 1, 1896, as compared with the year previous. But not only has the business increased with such great strides during the year, but the tendency to turn itself into the best class of service, metallic circuit, has continued without abatement, or rather has increased rapidly. Jan. 1, 1896, finds the total number of metallic stations 94,747, being a gain during the year of 40,067 over the number with which the year began. A comparison with the figures of the first of the last four years may be interesting. They are as follows:

These figures show increase from year to year: Jan. 1, 1892, showed 11,584; Jan. 1, 1893, 23,053; Jan. 1, 1894, 37,648; Jan. 1, 1895, 54,680; Jan. 1, 1896, 94,747.

In connection with this fact should be noted the increase of 33 per cent. in the number of toll line conversations, the metallic circuit subscribers being large users of that class of service.

In the Long-Distance Company's system there were on Jan. 1, 1896, in operation 5,804 miles of pole line and cables and 90,251 miles of wire, connecting 149 offices, an increase during the year of 1,187 miles of pole line and cables, 14,695 miles of wire, and 14 offices.

The introduction, in many of the larger cities, of the measured service system, to which reference was made in preceding reports, has been productive of good results in bringing the service within the reach of many who, not having occasion for large use of the exchange connection, did not feel justified in paying the rates which would entitle them to unlimited service.

During the year the companies leasing instruments expended for new construction $6,463,000; for addition to real estate, $465,000, and for repair and reconstruction, $7,223,000, making a total of $14,151,000 applied to extension and care of the telephone plant in the United States.

Expenditure upon this scale has now been going on for many successive years, and has resulted, not alone in the building up of a very extended telephone system, but in bringing that system, throughout the country as a whole, to a high state of efficiency.

The principal cities and towns through most of the States east of the Mississippi are now connected by wire, and conversation can be held by telephone over distances of 1,500 miles, which is more than twice the length of line anywhere brought into use for this purpose outside the United States.

The stockholders re-elected the directors and voted to increase the capital stock from $21,500,000 to $23,650,000.

Chairman pro tem. W. H. Forbes said: "The sale of 21,500 shares at $200 a share would yield about $4,300,000, and the necessities of the company during the coming year will just about absorb that amount of capital, so far as we can see."

The total wire mileage at the end of 1895 was 459,728, an increase of 63,054 in twelve months. The number of stations was 281,695, an increase of 38,263. The estimated number of exchange connections daily in the United States, made up from actual count in most of the exchanges, is 2,351,420, or a total per year of about 757,000,000. The number of daily calls per station varies in different exchanges from 1 to 16 3-10, the average throughout the United States being 8⅓, which shows a slight decrease from last year in the average use made of the telephone, by each subscriber, due to the introduction of the measured service system. The average cost to the subscriber varies, according to the size of the exchange and character of the service, from less than 1 to 10 2-10 cents per connection. The extra territorial and wire mileage at the end of 1895 was 215,687 miles, an increase of 35,130.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—VII.

BY

Wm. Baxter, Jr.

AS stated above, the weight of motors is about 2,200 pounds; but, if mounted on the axle, the armature shaft, the gears and casing would not be required, and this would reduce the weight by about 400 pounds, which would bring the weight of motors proper down to about 1,800 pounds each, or 3,600 pounds for the car equipment. This work, it must be borne in mind, is performed with armatures 18 inches in diameter, and, therefore, is much below what can be accomplished with machines of much larger capacity, in which the diameter of armature would more nearly approach to the diameter of the wheels. But even the above figures, which are far below what can be done on a large scale, show that a horizontal effort can be obtained equal to more than 22 per cent. of the weight of motors, and this is on the assumption that the motors are mounted on the axles. The actual performance of the machines above referred to (as they are built, that is, single reduction machines) shows a horizontal effort equal to about 70 per cent. of their total weight.

The energy output, when reduced to motor on the axle basis, would be about 23 horse-power, which is at the rate of 156 pounds per horse-power; but this also represents a speed of about 12 miles per hour. The same weight at 48 miles per hour would give four times the output, or 1 horse-power to 39 pounds.

These figures, which are taken from actual results of machines in every-day use, show conclusively that it is possible to mount motors on the axles of trucks having 42 to 48 inch wheels that will exert a horizontal effort equal to 40 or 50 per cent. of their entire weight and give an output at 50 miles per hour of 1 horse-power for 20 pounds of weight, or even less. It will thus be seen that the assumption that motors can be built that will do four times as much work as locomotives of the same weight is well within the limits of possibility, for only about 50 per cent. of the weight of engine and tender rests on the driving wheels, and, therefore, unless the traction co-efficient is taken as high as 25 per cent., the locomotive wheels would slip with a load behind them that the electric motors would draw without trouble.

In the foregoing paragraphs the capacity of locomotives has been assumed to be proportional to the weight on the driving wheels. This, in fact, is the true measure of their capacity at slow speeds; but, when the velocity increases beyond a certain point, other factors enter into the calculation, and then the weight no longer stands at the limit of the capacity. Somewhere above the speed at which weight on drivers ceases to be a measure of capacity the horizontal effort becomes less and less as the speed increased; not only that, but the portion available to draw the train also becomes a smaller percentage of the whole. These conditions also hold good for electric motors, but to nothing like the same extent. This will appear more clearly after the following explanation:

At slow speeds the only resistance to the motion of a train is the friction of the axles and the rolling friction of the wheels on the track, that is, assuming the track to be level. As the speed increases the atmospheric resistance begins to make itself felt. From that point onward the horizontal effort is expended partly in overcoming head or atmospheric resistance and partly in train resistance. The higher the speed the greater the head resistance.

Now, if a locomotive could, at all velocities, maintain a constant torque, then the load it could draw at any speed would be equal to the horizontal effort due to the torque, less the head resistance. But the locomotive cannot maintain a constant torque, because, as the speed increases, a point is soon reached where the boiler is no longer able to keep up the supply of steam required to maintain the maximum pressure in the cylinders. As the speed increases, the supply falls still shorter. As a result, from that speed at which the capacity of the boiler begins to be taxed, the torque begins to drop. We, therefore, find that when a point is reached where the head resistance begins to balance a large proportion of the horizontal effort, the useful capacity of the locomotive, or its ability to draw cars behind it, rapidly decreases. As soon as a speed is reached when the boiler fails to keep up the

necessary supply of steam, the decrease in effectiveness becomes still greater, because we then have a constantly reducing horizontal effort, as the speed increases, and a constantly increasing proportion of this effort required to overcome head resistance. Now, it is quite evident that under these conditions a speed is soon reached where the entire capacity of the locomotive is required to overcome the atmospheric resistance, and then the efficiency of the machine becomes zero.

These conditions do not obtain to the same extent with electric motors. The resistance of the atmosphere, it is true, has to be overcome in either case, but the horizontal effort of the electric motor can be kept at its maximum at any desired velocity; therefore, we have the case of a constant quantity being reduced by a gradually increasing quantity, against a decreasing quantity being reduced by an increasing quantity. In the case of the electric motor we reduce the effective capacity by whittling down at one end, but with the locomotive we reduce the effective capacity by whittling down at both ends.

The locomotive carries the source of energy on its back, so to speak, and, therefore, its capacity is limited, but the electric motor derives its energy from the power station, which is a practically unlimited source. Every electrical engineer knows that if a motor will give a certain torque at one speed it can be made to give the same torque at any other speed by simply changing the winding to suit the desired velocity. If two motors are mounted on each truck of the motor car, they can be so connected as to be operated four in series, two in series and two in parallel, or four in parallel. With such an arrangement, the maximum working torque could be obtained at 20, 40 or 80 miles per hour, or at 15, 30 and 60, or 25, 50 and 100, or at any other set of velocities having the ratio of 1, 2 and 4 approximately.

The above statement holds good for any speed, because the torque in a constant field is proportional to the ampere turns on the armature, while the electromotive force is proportional to the number of turns of wire. Now, if we place half the number of turns of wire on both the field and armature and double the current, the magnetic flux through the field will be the same and the ampere-turns on armature will be the same; therefore, the torque will be the same; but the number of turns of wire on the armature will be one-half, and, therefore, the electromotive force will be one-half, and under the same difference of potential between terminals the speed would be doubled.

The saving in energy required to move a train by reason of the saving in weight of motors would not be very great for freight service, owing to the fact that the weight of the locomotive and tender does not constitute a very large proportion of the whole, as will be seen by reference to the following brief calculation of the power required for such service.

Estimate of Power Required to Draw an Axerage Freight Train on the Pennsylvania Railroad, and Coal Consumed Per Mile:

Average number of cars per train (See Table 7)	30
Average weight of car, pounds	22,000
Total weight of cars, 30 x 22,000	330 tons.
Average weight of freight per train (see Table 7)	317 tons.
Weight of locomotive	75 tons.
Total weight of train	722 tons.

Average speed (see Table 7) 15 miles per hour, or 1,320 feet per minute. Traction resistance, 8 pounds per ton; horsepower to draw train is:

$$\frac{722 \times 8 \times 1320}{33{,}000} = 231 \text{ h. p.}$$

This is the power required on a level track. Making an allowance of 25 per cent. to cover extra effort going around curves and up grades, we will have, say, 290 horse-power, and this at a coal consumption of 6 pounds per hour would equal 116 pounds per train mile, and the total amount of coal consumed by all the freight locomotives on the road for one year would be:

$$\frac{20{,}400{,}355 \text{ (train miles)} \times 116 \text{ (lbs. per mile)}}{2{,}000} = 1{,}183{,}220 \text{ tons.}$$

This calculation has been carried out to the point where it shows the total amount of coal required to haul all the freight trains on the Pennsylvania Railroad for one year, so that the figures so obtained may be used later on in making an estimate of the relative cost of doing the work of this road by electricity as compared with steam. For the present, however, we are only concerned in showing the relation between weight of train and motive power in the two systems and relative cost of power for work performed. We will, therefore, only use here such of the above figures as may be required for that purpose.

The total weight of train, as given in above estimate, is 722 tons, and the weight of locomotive and tender is 75 tons, or about 10.4 per cent. of the entire weight. Now, if we should replace the locomotive by a motor car (which could be a large caboose car), the only additional weight would be that of the motors, which, as has been shown, would be less than 25 per cent. of the combined weight of locomotive and tender, or, in round numbers, 19 tons. The total weight of train would then be reduced to 666 tons, and the weight of motors would amount to about 2.85 per cent. of the total weight, instead of 10.4 per cent., as is the case with steam. The weight of the same train, when drawn by motors, would then be about 92.2 per cent. of the weight when drawn by a locomotive. The saving in power would, therefore, be nearly 8 per cent., and this is in freight service, where the weight of engine only constitutes about 10½ per cent. of the total. In passenger trains the reduction in weight would be very much greater, as the following will show.

THIRD ANNUAL MEETING OF THE TEXAS STREET RAILWAY ASSOCIATION.

THE third annual meeting of the Texas Street Railway Association convened at Galveston on March 18, 1896, with the President, W. H. Sinclair, in the chair. After an opening speech by the President, the convention got down to business and began discussion of various subjects, as follows:

FARES.—Whether the use of tickets of any sort should be advised; if a reduced ticket, in what form and how handled and sold. Only one railway represented sold reduced fares and none sold children's tickets. The Dallas roads require full fare for all children, except babes in arms; others, all children occupying seats.

EMPLOYEES.—The question of whether time was wasted and accidents added to by not using conductors. Cost of a conductor is $547.50 per year; the general length of time of employment is 12 hours—an average pay of $1.55 per day. Some pay by the hour, some by the day and some by the month. It was generally conceded to be a good plan to increase the pay after certain length of service. One road works its men four days and they are off one; another two days, and off one, except for relieving times. Other roads use three men to two cars, one man being a swing-run man.

Considerable discussion was had as to what are repairs and what are properly expenses. Mr. Hayward, of Houston, submitted a blank specification, which was generally approved.

POWER.—Only three roads could give definite figures on the cost of power per mile; they were, .0177, .0144 and .014, the latter under hired power. One road other than these, although not giving definite figures, must have a lower rate, because they have water power, and pay very little for it.

Considerable discussion was had as to the amount of training a man ought to have in order to save power, and the kind of training.

On the second day's session, March 19, the representation was as follows: Dallas City Railway Company, Houston City Street Railway Company, Galveston City Railroad Company, Fort Worth Street Railway Company, Laredo Electric & Railway Company, Austin Dam. & Suburban Railway Company, Austin Rapid Transit Railway Company, Queen City Railway Company, of Dallas.

The president presented extracts from the Connecticut and Massachusetts Railway Commissioners' reports, which in general show: That there has been a slight increase in the income for the year ending Sept. 30, 1895, and considerable decrease in cost of operation; but that the cost is still, in the lowest case, 68.93 per cent.; in the highest, 76.13 per cent. Of the 85 roads in the list, which includes St. Louis, only 46 have paid dividends.

ELECTROLYSIS.—Several instances were given of supposed destruction by electrolytic action; in few of the cases could this be definitely traced, nor was there any united opinion as to plans of overcoming the trouble. It was the general opinion that heavier bond wire was necessary. Messrs. Hayward, Urie, Hendricks and Wakefield all gave instances of trouble. In one case a six-inch condensing pipe had been perforated, but was afterwards encased in the tunnel, and so far with good results. In another case water pipes had been badly damaged, but no main pipes. In another, service pipes only had been damaged, and the water superintendent advised connecting to the water pipes direct. In another city the water superintendent refused to allow such connections. In one city the electrician had recommended that they encase the service pipes in vitrified clay sewer pipes. Some discussion was had upon the plastic bond; only one member seemed

to have much knowledge of it—Mr. Young, of Galveston. He advised its use, and maintained that it was not affected by the up-and-down movement of the rails that it joins.

REPAIRS OF TRACK.—Messrs. Hayward, Drake and Hendricks advocated the heaviest rail possible. Mr. Wakefield said: "Will the investment not reach a point where it ceases to be economical?" Mr. Hayward said: "The difference in cost, at the present price of rail, between 35 lb. and 75 lb., would be $1,700 per mile only; add to that about 10 per cent. more for labor and handling." Mr. Drake said: "The labor and the mere handling of the rail is a small percentage of the total expenditure for labor."

Opinion was general that the T-rail was proper, except where paving blocks were used; and the opinion of the majority was even then that the T-rail could be so blocked as to prevent trouble.

The President—"I think the city authorities in general are rapidly coming to the opinion that the T-rail has not the objections that have been formerly urged against it."

Mr. Hayward cited a case where the T-rail was specified for macadamized streets. "It costs from ten to fifteen per cent. less than girder, especially when you consider the difference in the cost of fittings, connections, etc."

Mr. Sinclair—"The salt air in Galveston corrodes our rails rapidly, no matter what the weight; but we find that the labor of keeping up the joints of light rail is enormous."

Mr. Drake—"We find that the difference between the 25 lb. and the 60 lb. rail is more than saved in truck and car body repair account."

Mr. Hendricks suggested that a quicker stop could be made on heavy rails than on light; he advised ties close together.

OVERHEAD WIRES.—A T-wire reversed was talked of and a cut shown. Mr. Hendricks said: "I saw this in the midst of a sleet storm, and it did not seem to be affected by the extra weight more than other wires, and because of the fastening, arcing and consequent pitting of the trolley wire will be prevented at the cars."

Mr. Young—"Regarding the bi-metallic wire, it is guaranteed to have a tensile strength of 5,164 pounds; size 00; weight 60 pounds less than copper; has steel core; cost about half that of copper." The general opinion was, however, that a No. 0 hard drawn copper was standard.

MOTORS.—As to the life: Experience of Messrs. Hendricks and Wakefield, armature life, two years. Mr. Sinclair, of Galveston, one year.

Mr. Drake—"Our armature man showed me where armatures had become crystallized, probably by heat or overload." General opinion was that overload was the principal cause of the destruction of armatures.

POWER.—The price of coal was found to be $3.65, $2.50 and $4.10 in front of boilers. The mileage of cars per day was from 100 to 180. Nut and slack coal mixed was used, excepting in one case, where Arkansas was used.

CAR BODIES.—One member had built new and repaired several car bodies; does not advise building new ones locally.

INSURANCE.—Discussion under this head covered a wide range. Briefly, the insurance companies were charging from 2 per cent. to 3½ per cent. on frame power house buildings and cars on track and in shed attached; from that on down, according to the building, until in detached car house, the price is 1¼ per cent.

Mr. Drake suggested the organization of the Texas Street Railway Mutual Insurance Company, and that ten per cent. of the gross earnings of each line, together with the regular insurance charges, according to board rates, be paid into the treasury annually; that a certain percentage be kept in reserve. With the rest of the money employed, after $100,000 was paid in the treasury, a corporation could be regularly organized. Until that all payments would have to be upon honor. A permanent committee upon insurance was appointed as follows: Carl F. Drake, of Austin, chairman; H. C. Chase, of Houston City Railway Company; J. L. Sale, of Dallas.

CAR WHEELS.—Various makes and styles of car wheels were discussed pro and con., and there seemed to be no unanimity of opinion. It was conceded that the cost of the wheels was not the principal item, but the cost of taking them off and putting them on, and the taking of the cars out of service. It was therefore argued that the best wheel possible should be obtained. It was found that the soft cast shoe was generally used and recommended, though some had the cast and wrought mixed.

TIES.—Cost of ties was found to run from 25 to 55 cents, delivered; cypress, longleaf pine and oak. The cypress for damp soil was found to have long life, but the other should be treated. In treating ties Mr. Drake suggested that the ends should not be covered or painted, as that would prevent the sap from running out in the process of curing, and fermentation and internal decay would result. A white oak tie was thought about the best.

LITIGATION AND ACCIDENTS.—The cost ran from $500 to $2,500 per annum, exclusive of attorneys' fees, which average about $1,200. It is the general opinion that about 75 per cent. of the amount of damages paid was wrong and that the judgments were due to the general feeling against corporations and false swearing.

METHODS OF INCREASING REVENUE.—Discussion under this head covered a very wide range. One instance was given where an $80,000 park had brought in $30,000 per annum increased revenue at a small additional expense. Another instance was given where a negro park cost about $3,500, and paid for itself many times during the season.

Mr. Hayward—"I find it is absolutely necessary to study the people closely before presenting them an attraction."

Under general discussion—It is found that where a band had been successful in one place, in another it was an absolute failure, no matter how good the music. It is found that people will not pay a fare and then pay admission to any appreciable extent.

Mr. Drake—"We tried to give good entertainments and charge a small admission, but found it was not patronized; we then gave very ordinary entertainments free, and had to turn people away." Mr. Drake believes in an amusement circuit. Mr. Hendricks found that a negro park paid, and that band concerts took very well.

Mr. Wakefield—"We find that in Dallas the factory man is the one who patronizes the cheaper entertainments, and we have not enough of this class to make it pay. Wealthier people want attractions that cost more than the increase in business warrants."

Mr. Urie—"We find it profitable to keep in with the baseball people; they are well patronized at Galveston.

On the question of appointing a committee on summer attractions, no action was taken.

The Insurance Committee was made permanent, and the President and Secretary were added to it in an advisory capacity. W. H. Sinclair, of Galveston, was elected President, and Carl F. Drake, of Austin, Vice-President; C. L. Wakefield, of Dallas, Secretary and Treasurer. These, with A. H. Hayward, of Houston, and George B. Hendricks, of Fort Worth, form a directory of five.

The next meeting will be held at Austin on the third Wednesday in March, 1897.

COMPLETION OF THE PITTSBURG TROLLEY CONSOLIDATION.

The various Pittsburg traction lines embraced in the new deal, backed by Philadelphia capital, went into the formal possession of the new owners on April 2. The lines are the Pittsburg, the Citizens' and the Central Traction companies, the Duquesne Electric system, the Pittsburg, Allegheny and Manchester Railroad and the Allegheny Traction Company.

The terms of the consolidation have been hashed and rehashed. The capital stock of the consolidated company will be increased and there are promises of great improvements in the service. The Fort Pitt line, it is expected, will commence running cars out Liberty avenue by April 20. The cables on the Citizens' and Fifth Avenue lines are to be replaced with trolleys and later on the cable on the Central will be abandoned. A new power house is to be built on the Allegheny River front, between Forty-second and Forty-third streets, and it will furnish power for all the lines on the system. All-night cars running through to Wilkinsburg every fifteen minutes are promised on the Fifth Avenue line, and at longer intervals on other roads.

The transformation of the three cable roads into trolley systems is to cost $4,000,000, and work will be begun as soon as the new Fort Pitt road is in operation. It is proposed to build several long suburban extensions of the present lines in a few years. The cable plants and tracks that are to be eliminated cost $12,000,000 for construction.

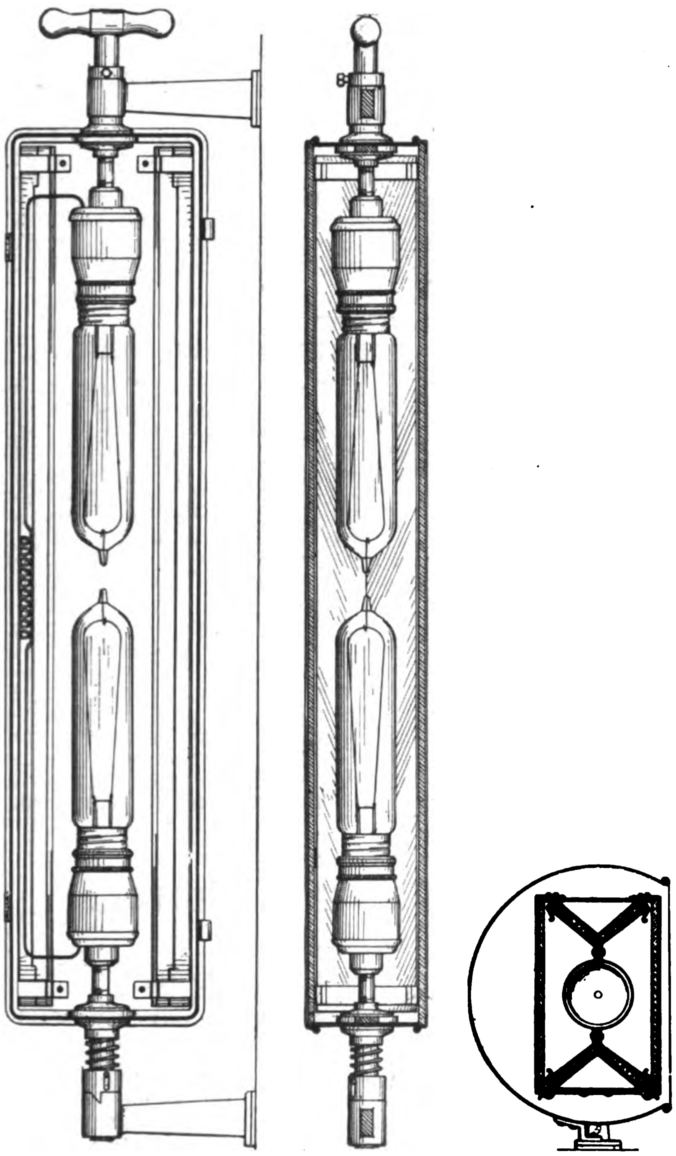
FIRST ELECTRIC LOCOMOTIVE FOR CANADA.

A dispatch from Montreal of March 26 says: The Canadian Pacific branch has been leased for thirty-five years to the Hull Electric Company, which will convert the road, which is nine miles long and connects Hull and Aylmer and the Pontiac and Pacific Junction Railroad, into an electric road. An electric engine, the first to be used in Canada, will be put on. The company also lights Hull and Aylmer by electricity.

MR. KEELY, of motor "fame," now has a vibratory dynamo, and his stockholders want him to get a patent on it as soon as possible. Then more money can be raised. Let the patent be secured by all means, if possible.

ENGLE ILLUMINATED ROUTE INDICATOR.

In many of our large cities it is customary for street car companies to paint all their cars of one color, as, for example, in Philadelphia, where the only distinguishing mark to indicate the different lines is a small wooden sign-board at the front and rear of the car, suspended above the dashboard, upon which is inscribed in black letters, often upon a yellow ground, the destination of the car. While this, even in daylight, is hard to decipher even at a short distance, it is almost, if not entirely, invisible at night, causing a great deal of annoyance and vexation to the traveling public, who not infrequently, through their inability to read the sign, get on the wrong car, very rarely discovering their mistake until a fare has been exacted.



ENGLE ILLUMINATED SIGN ON STREET CARS.

FIGS. 1, 2 AND 3.

To remove this vexation Mr. Robert H. Engle, of Philadelphia, has devised and recently patented an ingenious revolving, transparent, electrically illuminated sign. Fig. 1 represents a longitudinal interior side view of the sign and contents, the casing of which is made of sheet metal. Fig. 2 is a sectional plan view of the same, looking down from the top, showing lamps and reversely inclined reflectors. Fig. 3 represents a transverse section through the middle of the sign, showing the reflectors transversely inclined, and the upper and lower reflectors reversely inclined. These reflectors are set at an angle of inclination to obtain the maximum reflection.

As will be seen by reference to Fig. 3 the sign is inclosed by a semi-circular shield, for the purpose of obscuring the inner sign plate, so that only one—that is, the outward sign plate—is visible at a time. The casing of the sign is trunnioned on each end, and adapted to rotate in suspended hangers, which are usually mounted on the under side of the car hood, above the dasher. One trunnion is provided with a handle of insulating material, for rotating the sign, the hangers themselves serving as conductors to carry the current to the lamps, the lamps being connected in series or multiple according to voltage or the plan of the wiring of the car. On the opposite trunnion is a spring-actuated stop collar or clutch, on the ratchet principle, which limits the rotation of the sign, usually to a half turn, and secures it in proper position against any possible displacement by the jarring of the car, or otherwise.

One of the important features of this form of illuminated sign is that a maximum illumination is obtained by a minimum expenditure of current, by reason of the position and efficiency of the reflectors, together with the cylindrical form of lamp, it being possible to use a casing having one or many sign plates, and the diffusion of the light being so perfect there is no part of the sign plate better illuminated than the other, in fact, a more even distribution could not be obtained except at the expense of a great number of lamps, and a corresponding increase of power consumed.

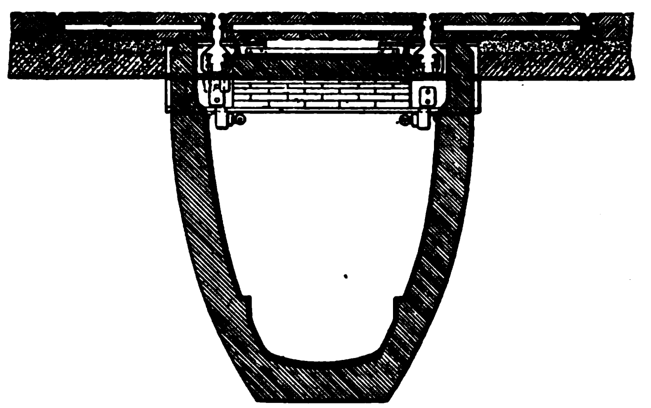
Aside from its uses as a route indicator for street cars, its adaptations render it admirable for advertising purposes, either as a fixed or rotatable sign, in any position where current is obtainable.

THE PROPOSED ELECTRIC RAILWAY CONDUIT IN PARIS.

In a paper recently read before the Société des Ingénieurs Civils, of Paris, on the subject of "Electric Railways with Underground Conductors," M. A. Lavezzari describes an interesting conduit-railway which is projected in Paris. The line will begin at the Place Cadet, near the Porte de Montmartre, and will extend through Rues Cadet, Rochechouart and others, to the end of Rue du Poteau. The road will be 1⅝ miles long, 1⅛ miles of which will be double-tracked, and the remainder single-tracked.

The heaviest grade is only 6 per cent., and occurs in Rue Rochechouart; the other grades average less than 3 per cent. The smallest curve radius is 105 feet. The localities traversed are of the most thickly populated in Paris, and those where travel is most active throughout the day, and it is expected that the line will transport 20,000 passengers a day.

The gauge of the track is one metre (39⅜ inches), and on the double-track portion of the line the conduits are arranged as shown. One rail of each track is of the usual girder type, but the other is a modified T-rail, and a similar rail is laid alongside it, with sufficient space between for the passage of the plow. The conductor conduit is located, of course, immediately beneath these rails, and contains both the positive and negative conductors, the rails not being included in the circuit.



PROPOSED DOUBLE-TRACK CONDUIT ROAD, PARIS.

The beams rest by means of cast feet on the two side walls of masonry of the main conduit, which is really a large sewer of the usual Parisian type, 5 feet 7 inches high under the arch, and provides ready access for the inspection and repair of the conducting system. To facilitate inspection and the transportation of material small trucks may be run along the lower part of the conduit; the track will be formed by two angle-irons set in the masonry.

The transmission of energy between the station and the cars is provided for by two feeders, positive and negative, which are supported in the upper part of the large conduit. These

feeders, for perfect separation, are held apart every thirteen feet by supporting insulators. Every 328 feet connection is made by branch conductors between the feeders and the working conductors, which latter are of steel and channel shaped. The branch connections are single conductor flexible cables, provided at one end with pins or shanks which fit in sockets attached to the feeders, permitting ready disconnection when it is desirable to cut out a section of the line.

The steel working conductors are supported every 6½ feet by cast arms bolted to the short beams forming the yokes. Double-petticoat porcelain insulators are provided for the conductors. Every 1,000 feet bells or telephone instruments will be installed in the large conduit to place each section of the line in communication with the power station. The collector has the form of a shuttle and rubs against the faces of the steel conductors, contact being maintained by means of springs. The shuttle is flexibly attached to a plow suspended from the car; both are so arranged that in case the car leaves the track they will detach themselves and become disconnected mechanically and electrically from the car without causing damage.

The station will contain three engines of 150 horse-power each, coupled by belts or ropes to three 500-volt dynamos, each of 100 kilowatts capacity. The cars will have a capacity, including the platform, of 36 passengers; there will be no top seats. All the cars will be equipped with two motors of 10 horse-power each, but will run in pairs, and the front car will contain all the controlling apparatus, the rear car being provided with motors only.

THE MOTOCYCLE RACE.

In "The Electrical Engineer" of Feb. 5, mention was made of the $3,000 offered to horseless carriages by the "Cosmopolitan Magazine" to be awarded after a race on May 30 over a course of about fifty-two miles, from City Hall Park, New York, to a point near the Cosmopolitan building, Irvington-on-the-Hudson, N. Y., and return to starting point. It has been found necessary to change slightly the percentages on which the award will be made, and, the maximum remaining 100, the divisions are now as follows: Speed, 35; simplicity of construction and durability, 30; ease in operating and safety, 25; cost, 10.

The committee of judges who have consented to act at this test are: Gen. Nelson A. Miles, U. S. A.; William P. Craighill, Chief of Engineers, U. S. A.; H. Walter Webb, vice-president N. Y. C. and H. R. Railroad, and John Jacob Astor.

Entries for the race should be sent early to the "Cosmopolitan Magazine," Irvington-on-the-Hudson, N. Y.

NEWS AND NOTES.

A SYSTEMATIC ARRANGEMENT OF THE ELEMENTS

In the "Zeitschrift für Anorganische Chemie" there is a paper by Julius Thomsen which is of some interest to those of our readers who are watching the steady, though gradual, approximation and identification of chemical and electrical truths. The author arranges the elements in ascending order of the atomic weights in three main groups, of which the first contains two series of seven elements, the second two series of 17 elements, and the third 31 elements. Hydrogen stands by itself. Electro-positive elements are at one end of each of the four smaller series, and electro-neative elements at the other. The new arrangement, amongst other things, serves to show relationships between the elements beyond those shown by the ordinary periodic scheme. The original paper may be consulted in the Zeit. Anorg. Chem., ix., pp. 190-193.

BRITISH EMPIRE EXPOSITION.

An exposition of the above name and character is to be held at Montreal from May 24 to Oct. 12, 1896. Three special prizes of $500 each are offered. One is for the most useful all-round invention connected with electricity and exhibited for the first time at this exposition. Mr. T. T. Stokes, the Commissioner General for New England, 88 Boylston street, Boston, can give information.

CONTEMPORARY ELECTRICAL SCIENCE.

In the "Physical Review" there is an advance paper by W. D. Bancroft upon the chemical potential of metals, vulgo, electromotive forces of cells. He finds that the potential does not depend upon the concentration of the solution, or upon the positive ion of the electrolyte. It may be described as a function of three things—the metal, the negative ion of the salt, and the solvent medium (usually water). Mercury and platinum acquire potentials of an opposite sign to those acquired by other metals with the same negative ion. A very handy water battery is described in the same periodical by Austin and Thwing. Strips of copper and zinc are bent into a peculiar shape round a set of fixed pegs. A copper-zinc couple run downwards side by side, then bend away from each other, and then down again. This makes a kind of shoulder, and the lower ends can be immersed by springing a homoeopathic vial on to the elastic couple and dipping the whole in water. A large number of such cells are placed side by side; the upper parts of the strips are bent again and soldered together, the junctions being mounted in a board and insulated with wax. One board can carry several hundred cells, and they may be filled by dipping the whole into a trough of water. There is a paper on Sahulka's effect in the "Wiener Berichte," 104, by F. Gold. The effect consists in a continuous current observed in an arc between iron and carbon poles fed with an alternating current. It flows from iron to carbon, and may be demonstrated by a magnetic needle. The arc has evidently less resistance in the iron-carbon direction than in the contrary. With a steady continuous current the arc is longer if the current flows from carbon to iron than if it flows from iron to carbon. —London "Electrician."

"FICKER" PHOTOMETRY OF COLORED LIGHTS.

In a recent number of the "Physical Review" an article by Mr. F. P. Whitman gives some account of the use of the "flicker" photometer in comparing lights of different color, and stating that this method approximates in convenience and accuracy to any of the ordinary photometric appliances using lights of the same color. The chief test by which this conclusion is arrived at is that different observers whose vision is normal obtain similar results; whereas, by other methods, the comparison of colored lights by different observers was found to give results often differing by 50 per cent. The flicker method of photometry is based upon researches made by Professor Rood, who has shown that if a rotating disc, rotating rather slowly, is painted with two different shades, either of gray or some other color, a flicker is produced, which, however, will gradually disappear if successive pairs of colors more and more alike are chosen. The author has adapted this principle to a photometer, which he calls a flicker photometer, in which a rotating sector disc is made to give intermittent comparisons between two colored lights on a photometer bar. It is found that differences in color do not, with such an instrument, affect the measurements.

LETTERS TO THE EDITOR.

WHAT WAS GILBERT'S MEANING?

Some questions having arisen as to the meaning of one of Gilbert's statements, I should like to point out that Gilbert's words are: "Electrica, quae attrahunt eadem ratione ut electrum." These may mean that electrics are those things which attract "for the same reason" as the amber, or "in the same manner" as the amber. Most translators have preferred the first rendering. I did so myself until further study revealed Gilbert's actual position with respect to the scientific thought of his age.

Those who prefer to regard Gilbert as an Aristotelian closing the epoch of Greek philosophy, may logically insist on the words, "for the same reason," being the proper translation, since the comparison then rests on a similarity of hypotheses. Others who, like myself, after prolonged consideration, become forced to the conclusion that Gilbert is the great forerunner of the inductive philosophy, will deem "in the same manner" a rendering in better harmony with his work, since the comparison then rests on observed fact.

PARK BENJAMIN.

New York, April 2, 1896.

THE COLLINS SMOKE PREVENTION TESTS.

Mr. B. R. T. Collins' article on comparative tests of smoke preventing furnaces is one which I think all practical engineers will appreciate. In looking over Tables 1 and 2 for economic evaporation and maximum capacity, it appears to me that the temperature of feed water in both tests is extremely low, the highest average temperature being only 100.4 degrees

F. Undoubtedly there is some reason for this. It also seems to me that the consumption of coal per horse-power hour is excessively high, even taking into consideration the low temperature of feed and the low grade of fuel. I am sure there are others like myself who would be pleased to hear from Mr. Collins on the above. C. DOUTRE, E. E.
Richelieu & Ontario Navigation Co.,
Agency, Montreal, March 14, 1896.

SOCIETY AND CLUB NOTES.

DR. EMERY ON ELECTRICITY IN RELATION TO STEAM AND WATER POWER.

DR. CHARLES E. EMERY, of New York, in his lecture at the Franklin Institute, on "The Relations of Electricity to Steam and Water Power," said that at present electricity acted simply as a convenient means of transmission, making it possible to utilize water power in mountain fastnesses and at considerable distance from centers of trade and mechanical operations and transmit it where the energy can be utilized. It would be possible through a pair of conductors ⅛ of an inch in diameter to transmit sixty horse-power 133 miles if the electrical pressure could be practically maintained at 20,000 volts. This voltage has been employed experimentally, but practical transmissions are made at 10,000 volts.

"It is now considered advisable," said Dr. Emery, "to employ all the power of a water power development to generate electricity and use electric transmission in the place of mechanical, not only to the manufacturing establishments in the vicinity, but those at a distance." The lecturer said that for a development of 80,000 to 100,000 horse-power the company could afford to sell power on the different premises in the vicinity for $12 per year net maximum horse-power, and in general could readily obtain $15 to $18 per horse-power. He considered that power could be profitably sold from such development at a distance of twenty miles for $18 to $20 per horse-power in large units, but that the cost of distributing the power to small consumers about the city would be so great as to leave little advantage to them, compared with the cost of steam power.

Dr. Emery believes that large water power may be developed and transmitted locally with advantage, in competition with steam power, even where fuel is cheap; that transmissions to a distance of twenty miles are warranted if power is sold for twenty-four hours or in large units, and stated that where fuel is $3 per ton or over, electric transmission is very generally applicable.

With regard to the above abstract, taken from one of the Philadelphia papers, Dr. Emery writes us: The abstract of my Franklin Institute lecture is correct as far as it goes, but for reproduction in an electrical journal some of the omissions would have an important bearing. It is true that on account of the low price of electric apparatus, the field of electric transmission has been greatly enlarged, and when the cost of apparatus is considered with the probable cost of developing a water power on a very large scale, transmitted power should be sold as low as stated. This does not mean that companies now established can do this, and if not they will have great difficulty in competing with steam power where coal is cheap. My figures on the cost of steam power have been often confirmed, but it is gratifying to find the evidence of Mr. Field ("Cassier's Magazine," March, 1896) that variable steam power for electric plants is actually being obtained at about 1 cent per horse-power hour, as I claimed in my Institute paper at the Niagara Falls meeting. It is only power from water, for which the cost is based on a horse-power year, whereas the cost of steam power depends on the h.-p. hour, most of the expenses decreasing as the power is decreased; so Mr. Foster in reporting the cost of steam power by the h.-p. year ("Electrical Engineer," June 26, 1896), not only deceived himself, but many others. Had he reported on the "horse-power hour" basis for steam, and compared with the cost of water based on the maximum power, as is necessary, he would have found that the charge for transmitted power must, for a variable demand, be less than the cost of steam power on a 10-hour basis, although such power is actually distributed through 24 hours. The transmitted power should readily be offered at such a price, where the high tension transmission can be carried directly to the actual points of utilization. When, however, the cost of a subsidiary system of distribution, with promotion expenses incident to such a work in a city, are added, it does not appear possible for transmitted power to compete with steam power, where coal is less than $3 per ton.

HENRY ELECTRICAL CLUB.

AT a meeting of the Henry Electrical Club, held on March 20, Dr. Louis H. Laudy delivered a lecture on "The Arc Light."

The electric arc, the lecturer said, though used during many years for lighting purposes, was yet imperfectly understood, and the exact nature of the physical changes which took place in it were still very much of a mystery. Many investigators were now at work on the subject, and the lecturer pointed out some of the phenomena which were being studied.

In common with nearly all systems of illumination the arc light depended on the incandescence of carbon. Arcs could readily be formed with many other metals, but the emissive power of carbon, together with its refractory nature and its cheapness, made it the best material for arc lighting.

In describing the conditions necessary to produce the electric arc the lecturer showed that the mere passage of a current between two carbon points had no other effect than to generate heat at the point of contact; but the moment the points were separated the gap between them was bridged by a stream of incandescent carbon vapor. On the position of the carbons and the distance of separation depended the character of the arc, whether flaming, hissing, or silent. Too short a distance produced a hissing arc; increasing the distance made it silent. As the resistance of the vapor between the points increased with the distance, more energy had to be expended to overcome a long than a short arc, and for that reason it was not economical to separate the carbons more than was necessary to avoid the hissing effect. To maintain the distance of separation constant was, therefore, the object most sought in the design of an arc lamp, and it was a problem which had taxed the ingenuity of inventors for many years.

One of the earliest attempts in that was the Jablochkoff candle, in which two carbon rods were mounted side by side, and separated by a partition of some refractory material. While that system of mounting the carbons maintained the distance of separation the same, it required the use of the alternating current, as otherwise one of the carbons burnt away more quickly than the other. The alternating current for arc lighting fell for a time into disfavor, for which reason—with some other objectionable features of the system, among which was the short life of the carbons—the Jablochkoff candle was now only a historical relic. Many other methods of regulating the distance between the carbons had been tried, some of them very ingenious, but few without some shortcoming which led to failure. It was curious to observe how, in this, as in other fields of invention, the same ideas had been tried, abandoned and reinvented.

The most successful system of regulation was that known as the differential, of which the Brush lamp was one of the earliest examples. The differential method of feeding was so called because it employed the opposing forces of two solenoids, one of high resistance, in shunt with the lamp, and the other of low resistance, in series with the arc. The low resistance solenoid acted to pull the carbons apart, while the high resistance solenoid, by neutralizing its effect, permitted gravity to move the upper carbon toward the lower one. As the current each solenoid received depended on the resistance of the arc, a balance was set up which preserved a constant gap between the carbons.

Clockwork, also, had been used to a great extent, particularly in lamps for projection purposes, where it was not only necessary to maintain a constant degree of separation between the carbons, but to keep the position of the arc itself always the same. The lecturer preferred hand regulation for that purpose and exhibited some lamps for projection which were easily and quickly adjusted by hand without the complication of clockwork.

Much of the success of an arc light depended on the quality of the carbons used, and in that respect constant improvements had been made with the result that flickering arcs, once so common, were no longer considered as an unavoidable characteristic of the system.

The electric arc was easily affected by the condition of the air surrounding it, and that had led to the principle of enclosing the arc in an almost air-tight envelope. Many difficulties were met in doing that, but there was no question about its having the advantage of giving a longer life to the carbons. The lecturer described the recent progress of arc lighting in connection with low potential circuits, and stated that the alternating current was gradually being regarded more favorably.

The lecture, which was listened to by a large and attentive audience, was illustrated with many interesting and striking experiments.

PARTIAL PROGRAMME FOR THE N. E. L. A. CONVENTION.

We have received from Secretary G. F. Porter a partial list of the papers and topics that will be presented at the nineteenth N. E. L. A. Convention, to be held in this city May 5, 6 and 7 next. The sessions will be held in one of the large rooms in the Industrial Building, Lexington avenue and Forty-third street. The hotel headquarters will be the Murray Hill Hotel, Park avenue and Forty-first street, within two blocks of the convention hall. Prices to delegates $2 and upwards on the European plan, $4 and upwards on the American plan.

Papers—"Single Phase Self-Starting Synchronous Motors," by F. H. Leonard; "Results Accomplished in Distribution of Light and Power by Alternating Currents," by W. L. R. Emmet; "Acetylene Gas," by L. A. Ferguson, Electrical Engineer of the Chicago Edison Company; "Evolution of the Arc Lamp," by L. H. Rogers; "Steam Boilers; Their Equipment and Management," by Albert A. Cary; "Electrolysis," by Capt. William Brophy; "Evolution of Interior Conduits from an Electrical Standpoint," by Luther Stieringer. Lecture—"The Light of the Future," by D. McFarlan Moore. Topic—"The Desirability of a Standard Socket," discussion to be opened by Alfred Swan.

MORE EXHIBITORS FOR THE NATIONAL ELECTRICAL EXPOSITION.

In addition to the long list of exhibitors published last week we have received the following supplementary names: Metropolitan Tel. & Tel. Co., 15 Cortlandt street, New York; Interior Conduit & Ins. Co., 527 West Thirty-fourth street, New York; Fort Wayne Elec. Corporation, Fort Wayne, Ind.; Electrozone Co., Morris Building, New York; American Electric Heating Corporation, Sear Building, Boston; Bourne Scrymser Co., New York City; J. T. Case Engine Co., New Britain, Conn.; De Veau & Co., Frankfort street, New York; N. Y. Safety Steam Power Co., New York City; Schiff, Jordan & Co., Vienna, Austria; Spon & Chamberlain, New York City; Syracuse Storage Battery Co., Syracuse, N. Y.; Telluric Manufacturing Co., 52 New street, New York; Thomson Meter Co., Brooklyn, N. Y.; Wendell & McDuffie, Havemeyer Building, New York.

NATIONAL ELECTRIC LIGHT ASSOCIATION.

The New England Passenger Association has granted a rate of a fare and one-third, on the certificate plan, from all points in their territory to New York and return, for all delegates and representatives attending the nineteenth convention of the National Electric Light Association, to be held in this city May 5, 6 and 7.

INHERENT DEFECTS IN FUSE METALS EXPERIMENTALLY CONSIDERED.

In his paper, entitled as above, read before the Franklin Institute, March 24, Mr. Walter E. Harrington emphasized the fact that fuse metals cannot be considered as the correct and safe means for protecting electric circuits. A fuse depends for its action upon the heating quality of the current; time and current combined melt fuses, C standing for current in amperes and T for time in seconds. A fuse does not operate the instant C becomes excessive, but it does when C^2T becomes excessive. A fuse is placed in a circuit to serve as a protection against some unforeseen accidental condition. In actual practice short circuits, crosses and grounds are almost exclusively the troubles met with, and do not exhibit the very conditions which fuses were designed to meet, namely, time and current. The current rises very high, far in excess of the rating and capacity of the fuse and the circuit the fuse is supposed to be protecting. It is the occurrence of short circuits which upsets the prevailing theories, as the fuse is intended only to meet a small percentage overloaded condition of circuit. Mr. Harrington's idea of the correct design of the magnetic circuit breaker is that it should have an inverse time element; its electro-magnetic mechanism should be designed to develop more energy than is necessary to trip its retaining catch; the additional energy developed should be applied directly to aid the opening of the switch; no springs should be permitted in its adjustment; insulation should not enter into the construction of the trigger or catch; all bearing pins and parts liable to corrosion or rust should be of phosphor-bronze and moving iron parts copper plated; and the armature or plunger should not act on the retaining catch or switch-arm unless a free preliminary movement precedes such action.

THE MEXICAN EXPOSITION.

As we have received some inquiries regarding the progress of the proposed Mexican Exposition, we have, for the benefit of our readers, obtained some facts in regard to the matter, which may be of interest to those intending to exhibit.

It seems that the exposition is not being undertaken by the Mexican government, but is in the hands of a private corporation who have obtained a concession or franchise from the government to arrange and conduct an exposition. The Mexican government has not given any official sanction to the scheme other than the franchise, nor will it appropriate any money to carry it on. Consequently if the exposition succeeds it will have to depend for funds entirely outside of the Mexican government.

The impression has been allowed to prevail throughout the United States that the exposition is being undertaken by the Mexican government and a number of States have already appointed commissions to represent them. Acting under this impression, Gov. Morton some time ago advised passing a bill in the New York legislature authorizing the appointment of a commission and appropriating money that the State may be suitable represented, but as nothing has since been done, it is quite likely that he has obtained the facts in the case and is deferring action on the matter. While we are not disposed to discourage this scheme at all—in fact, we believe an exposition in Mexico would be an advantage to both countries, yet judging from the Mexican papers and other sources of information it is not quite certain that the exposition will be held under the present auspices, and we would advise those who propose paying for space to wait a little, or at least to look into the probable chances of success which the exposition company has of carrying on such an undertaking. The date of opening has again been postponed until December 1 of this year, but as none of the buildings has been started it is very doubtful if it can be opened at that time.

A KELVIN JUBILEE.

On June 15 and 16, a celebration will take place at Glasgow to commemorate the completion by Lord Kelvin of his fiftieth year's tenure of the chair of natural philosophy at the University of Glasgow. A committee has been formed by the city and university to make arrangements, and bodies with which Lord Kelvin is connected have been asked to name representatives to whom invitations can be sent, for the occasion. President C. H. Wilmerding has appointed Mr. T. C. Martin to represent the National Electric Light Association at this interesting jubilee.

LECTURES ON LIGHTING OF BUILDINGS.

Mr. Clayton W. Pike, of the Falkenau Engineering Company, of Philadelphia, who delivered a course of four lectures before the senior class of the School of Architecture, Philadelphia, last year, will repeat the subject during March and April of this year in a series of six lectures.

The treatment of the subject covers modern engineering practice as to the various methods of lighting buildings, the necessary work to be done by the architect in preparing for the installation of electric lighting plants, and the relation of the architect's work to that of the electrical engineer.

AN ADDITION TO THE WHEATSTONE BRIDGE FOR THE DETERMINATION OF LOW RESISTANCES.

Mr. J. H. Reeves read a paper on the above subject before the Physical Society.

The piece of apparatus described can be used for measuring the resistance of metre lengths of wires of low resistance, the only additional apparatus required being a sensitive galvanometer, a Post Office form of resistance box, and a metre bridge. It differs from the ordinary Kelvin bridge in that instead of balancing by varying the length of the standard wire between the two contacts, the distance between these contacts is maintained constant, as is also the length of the wire which is being measured, and balance is obtained by altering other resistances in the network. The author has made a number of tests which show that by his arrangement the resistance of metre lengths of copper wires between the limits of No. 22 S. W. G. and a stranded cable of seven No. 16's can be determined with an accuracy of 0.1 per cent.

PERSONAL.

MR. P. E. SULLIVAN has been appointed superintendent of construction department, with the Standard Underground Cable Company, under Mr. George L. Wiley.

MR. F. L. FROST, of Albany, N. Y., has been appointed electrical expert in the State Hospitals at a salary of $2,500. His appointment comes through State Architect Perry, who took his name fom the civil service list.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MARCH 17, 1896.

Alarms and Signals:—

SWITCHBOARD SIGNAL. I. H. Farnham, Wellesley, Mass., 557,527. Filed Jan. 16, 1896.

Consists of a support in which is inclosed an electromagnet having an iron sheath, and hung by its upper end at the entrance of a cavity in the support, and in front of the electromagnet.

Galvanic Batteries:—

GALVANIC BATTERY. E. S. Boynton, Brooklyn, N. Y., 557,355. Filed Feb. 21, 1895.

Comprises two or more elements grouped in one receptacle and having an electrolyte common to all. Known as the "multivolt" battery.

GALVANIC BATTERY. E. S. Boynton, Brooklyn, N. Y., 557,356. Filed Sept. 13, 1895.

Similar to above.

Distribution:—

MULTIPLE SERIES SYSTEM OF ELECTRICAL DISTRIBUTION. F. B. Badt, Chicago, Ill., 557,099. Filed Sept. 25, 1895.

Means for operating translating devices in multiple series.

DISTRIBUTION OF ELECTRIC CURRENTS. I. Kitsee, Philadelphia, Pa., 557,398. Filed Sept. 16, 1895.

Employs resistance varying with the varying need of current.

MEANS FOR TRANSMITTING ELECTRICAL ENERGY. T. W. Onderdonk, New York, 557,422. Filed April 9, 1895.

Consists principally of a motor shaft provided with a circuit breaker and an electromagnetic motor for operating a tool.

Dynamos and Motors:—

COMMUTATOR FOR HIGH VOLTAGE DYNAMOS. A. J. Oehring and H. H. Wait, Chicago, Ill., 557,218. Filed Aug. 20, 1895.

The segments are fastened by means of screws to the face of a wood disc.

FAN MOTOR. R. H. Hassler, Dayton, O., 557,384. Filed Nov. 27, 1895.

An electric motor with field and armature revolving in opposite directions in a vertical plane, a wheel attached to the armature and a second wheel attached to the field, the two wheels adapted to drive by friction a third wheel revolving in a horizontal plane and attached to a ventilating plane.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. W. D. Ray, Chicago, Ill., 557,229. Filed July 11, 1894.

Employs curved carbons.

CARBON HOLDER FOR ARC LAMPS. C. A. Pfluger, Chicago, Ill., 557,518. Filed Aug. 7, 1895.

Two pivoted clamping jaws with thumb screws, one adapted to control each jaw, and both to be moved simultaneously when desired.

SHADE FOR INCANDESCENT ELECTRIC LAMPS. S. O. Richardson, Jr., Toledo, O., 557,342. Filed Nov. 1, 1892.

A bulb formed of alternate series of horizontal thick and thin portions, the outer and inner surfaces of the said thick portions being parallel.

Measurement:—

ELECTRIC METER. C. P. Steinmetz, Schenectady, N. Y., 557,164. Filed Jan. 15, 1896.

A meter for a monocyclic system, consisting of a field magnet supplied by a resultant source of energy, transformers for establishing phase relations corresponding to those of the main line, and an armature supplied by the transformer.

Miscellaneous:—

MAGNETIC ORE SEPARATOR. O. M. Graves, North Yakima, Wash., 557,121. Filed June 17, 1895.

Magnetic needles projecting from an endless carrier, and a vertically pivoted oscillating hammer, in operative proximity to the edge of the needle carrier.

ELECTRICAL DENTAL PLUGGER. P. R. Skinner, Oneonta, N. Y., 557,159. Filed May 6, 1895.

Details of construction.

THERMOSTAT. W. S. Johnson, Milwaukee, Wis., 557,272. Filed March 24, 1894.

A single piece of platinum is made to operate as a contact piece in connection with both of the contact screws.

CABLE RAILROAD. W. M. Wood and J. C. Miller, Elmira, N. Y., 557,320. Filed Aug. 26, 1895.

Devices which can be operated quickly to close or open an electric circuit through suitable mechanism, located at the power house, to stop the cable quickly in case of an accident.

ART OF ELECTRIC DYEING. G. D. Burton, Boston, Mass., 557,324. Filed Sept. 25, 1894.

Consists in passing a current at 40 volts or more through the dyeing liquor, thus expanding the fibers of the material to be dyed.

ART OF AND APPARATUS FOR ELECTRO-DYEING. G. D. Burton, Boston, Mass., 557,325. Filed Oct. 31, 1894.

Similar to above.

ART OF AND APPARATUS FOR ELECTRIC DYEING AND SHRINKING. G. D. Burton, Boston, Mass., 557,326. Filed Feb. 25, 1895.

Similar to above.

CIGAR LIGHTER. J. Frye, Philadelphia, Pa., 557,375. Filed July 16, 1895.

An electric spark is employed to ignite a wick saturated with alcohol or similar material.

ELECTRICAL LIGHTING APPARATUS. R. A. Schoenberg, J. W. Flucker, A. N. Keedwell, New York, 557,434. Filed Dec. 5, 1895.

Gas lighting apparatus designed especially for burners of the Welsbach type.

ELECTRIC FLASH LIGHT APPARATUS. G. R. Lawrence, Chicago, Ill., 557,403. Filed May 17, 1895.

An electric conductor and a number of fuses adapted to complete the circuit on the pans or arms and to ignite the powder.

ELECTRIC GATE OPERATING MECHANISM. F. J. Dyett, Ilion, N. Y., 557,497. Filed Nov. 1, 1893.

A driving shaft having the reversing gears connected with the motor shaft, a clutch operating to alternately make one or the other of the gears fast with the driving shaft.

Railway and Appliances:—

TROLLEY POLE SUPPORT. N. H. Davis, Philadelphia, Pa., 557,114. Filed Nov. 8, 1895.

A pivoted spring support.

RAIL BOND AND ELECTRICAL CONNECTOR. C. E. Moore, Chicago, Ill., 557,139. Filed Oct. 9, 1895.

A flanged rail bond provided with a tapered sleeve adjusted by means of a screw.

RAIL BOND AND CONNECTION. E. A. Turner, Chicago, Ill., 557,174. Filed Sept. 7, 1895.

Sleeves driven into the rail in one direction and adapted to receive the enlarged end bond when inserted in the other direction.

ELECTRIC RAILWAY. P. B. Delany, South Orange, N. J., 557,258. Filed Oct. 10, 1892.

An electric heating wire arranged within the conduit and a conductor enveloping or partly enveloping the heating wire.

ELECTRIC CAR HEATER. J. G. Noyes, Milford, Conn., 557,282. Filed Aug. 16, 1895.

A corrugated heater-body containing electrical conductors embedded in cement in the corrugations on one face and perforations between the corrugations.

TROLLEY FOR ELECTRIC RAILWAYS. H. A. Seymour, Washington, D. C., 557,442. Filed Feb. 1, 1896.

An electromagnet adapted to maintain the trolley in good contact with the conductor.

RAILWAY SWITCH. L. A. Osborne, Newark, N. J., 557,338. Filed Nov. 26, 1894.

A solenoid actuating operating pawl, and means for giving return movement to the solenoid core and its attachments.

AUTOMATIC SWITCH. L. A. Osborne, Newark, N. J., 557,339. Filed March 4, 1894.

Means for energizing the coils of a ratchet wheel in mechanical connection with the frog carrier.

Regulation:—

REGULATING ELECTRIC MOTORS. J. Burke, Newark, N. J., 557,185. Filed Sept. 4, 1895.

Utilizes an auxiliary electromotive force to assist or oppose the line potential.

Switches, Cut-Outs, etc:

SNAP SWITCH. J. S. Gibbs, Hartford, Conn., 557,198. Filed Jan. 20, 1896.

Details of construction.

ELECTRIC SWITCH. C. G. Perkins, Hartford, Conn., 557,224. Filed Jan. 2, 1894.

Details of construction.

ELECTRIC CUT-OUT. R. G. Davis, Brooklyn, N. Y., and A. M. Torrance, Bennington, Vt., 557,257. Filed July 5, 1893.

A pivoted arm is adopted to be thrown out of engagement with the contact post.

RHEOSTAT. H. E. Heath, Windsor, Conn., 557,386. Filed Dec. 26, 1895.

Makes use of flexible non-conducting wire holders, with which the wire is interwoven.

Telephones:—

APPARATUS FOR TELEPHONE LINES. C. E. Scribner, Chicago, Ill., 557,153. Filed Aug. 17, 1895.

Permits the use on combined metallic and ground return circuits of automatic signals at the central station controlled by the switch hook at the sub-station.

APPARATUS FOR TELEPHONE LINES. C. E. Scribner, Chicago, Ill., 557,154. Filed Aug. 17, 1895.

A storage battery at the sub-station and means for charging from the central station.

TELEPHONE SWITCH AND SUPPORT. E. C. Paramore, Philadelphia, Pa., 557,284. Filed April 24, 1895.

The removal of receiver opens bell circuit without aid of springs.

OBITUARY.

WILLIAM BOARDMAN TOBEY.

THE sad news has reached us of the death at Guayaquil, Ecuador, of Mr. Wm. Boardman Tobey, of Pittsfield, Mass. Particulars as to the cause of his death are missing, but it is supposed that he fell a victim to the virulent fevers to which foreigners in these Southern countries only too frequently succumb.

Mr. Tobey, though only 27 years old at the time of his death, was on the high road to a brilliant career. After taking the degree of electrical engineer at Cornell, in 1889, he entered the Stanley Laboratory at Pittsfield, Mass., where he assisted actively in the design and construction of the well-known Stanley alternating-current apparatus. In the fall of 1894, Mr. Tobey became the manager of the S. K. C. Specialty Company, at Pittsfield, which position he held until the beginning of this year, when he resigned to accept the management of the Ecuador General Electric Company. It was while making a survey of the work to be inaugurated at Guayaquil that Mr. Tobey was stricken down.

In 1894 Mr. Tobey married Mrs. Frances Cooley Prescott, who survives him, and to whom, as well as the parents of the deceased, we tender our deepest sympathy. Those who were privileged to know Mr. Tobey will regret the untimely death of one so able and withal so courteous to all who came in contact with him.

W. T. M. MOTTRAM.

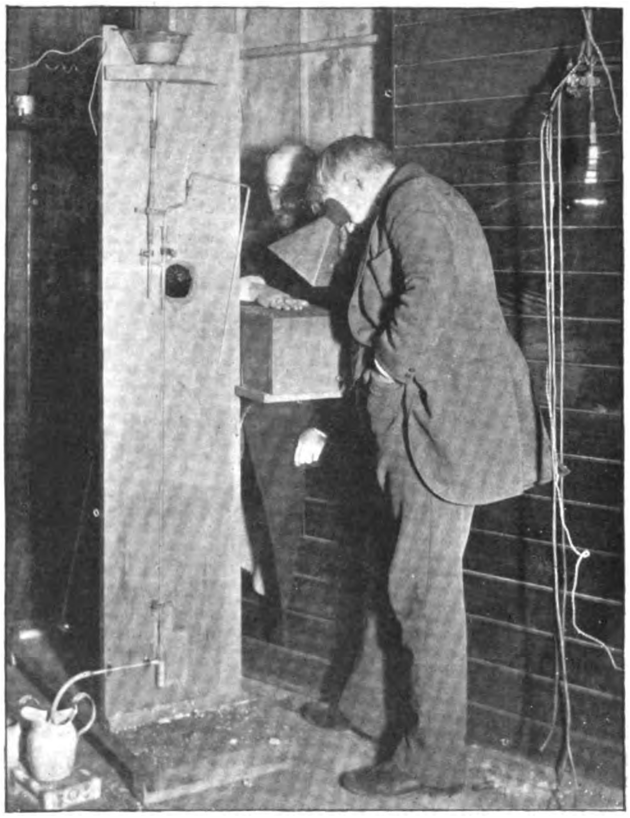
We learn with deep regret the news of the death at New Orleans of Mr. W. T. M. Mottram, a young Englishman of considerable ability, who had been for several years past actively engaged in electrical work in this country. He studied under

Professors Ayrton and S. P. Thompson in London, and then as an assistant to Mr. W. J. Hammer, took part in the installation of the Edison Holborn Viaduct station in 1881. He was also employed on the first plant installed in the British Houses of Parliament. After doing work in Germany for the Edison Company, he came to this country and was then for some time associated with the Edison and Sprague interests. He was at one time in charge of the Wilmington and New Orleans Edison stations. Of late years he had drifted into the contracting branch of work, and being a good engineer was able to leave behind him an excellent record in the design and construction of numerous plants. He was of amiable disposition and his fidelity to duty won him a great many friends. He leaves a widow.

Exhibition Notes.

EDISON'S PORTABLE X-RAY APPARATUS.

In addition to devising his simple and highly ingenious fluoroscope, based upon the properties of tungstate of calcium, enabling anybody to examine at will any object, whether moving or still, under the Röntgen ray, Mr. Edison has now put together a simple compact set of apparatus, by means of which the whole fluoroscopic and ray outfit can be carried from point to point and utilized on the spot for surgical operations and physical introspection. Mr. Edison is now building four of these sets which will be operated by his own staff in the Röntgen ray exhibit which he has very generously consented to make at the National Electrical Exposition in this city.



Portable Edison Fluoroscope Apparatus to be Used at the Electrical Exposition.

The picture shown herewith, taken from a flashlight photograph, made last week, is of Mr. Edison himself, at the Orange laboratory, studying a hand by means of his fluoroscope. The hand rests on a box which contains the battery, the induction coil and the Crookes tube. When the current from the battery is switched on to the coil and tube, the mercury pump seen on the upright board is also started, so that the tube is undergoing exhaustion while in operation. Mr. Edison has found that the tube works much better while thus used.

As will be seen, this apparatus can be set on wheels and rolled around a hospital, or put on the cars and shipped to the scene of a railroad wreck. At the exposition, people will be allowed to look at their own hands on the box, if they choose; but if they linger the circuit will be broken. In this way the procession will be kept moving. The fluoroscope will be of the hand size illustrated in "The Electrical Engineer" of April 1, but other sizes will be exhibited as well as those which surgeons can slip on the head so as to leave both hands free.

WHAT EXHIBITORS WILL DO.

Active preparations for the approaching exhibition at the Grand Central Palace are going on and many exhibitors, who have their plans well advanced, are ready to state what they propose to do.

The General Electric Company are preparing a very fine exhibit, based on the lines of their display at Atlanta.

The New York Edison Company, as already announced, has undertaken to show on a broad and comprehensive scale the many uses to which central station current can be put in the office, factory, hall, street and home.

The Abendroth & Root Manufacturing Company are putting in a fine boiler plant, which will not only supply steam to the exhibits of engines, but will embody some remarkable features of novelty in its care and management. It will probably be one of the most striking features of the show.

The Weston Engine Company, of Painted Post, N. Y., are about placing on the market a new engine, which will be shown first at this exhibition. It is to be called the "Imperial Self-Oiling" engine, and it will drive a dynamo of one of the leading makes.

The Bryant Electric Company will not go in for an elaborate display, but will show their standard sockets, switches, etc.

The Crocker-Wheeler Electric Company are not ready to announce their plans, but have a very fine and large exhibit in preparation, which will admirably illustrate the various elements and details of current generation and power transmission.

The Ball & Wood Engine Company will show one of their standard simple engines which they are completing for the large set of same to go in the new Siegel-Cooper building on Sixth avenue. It will be direct connected to a Siemens-Halske generator. It will be fitted with all their latest improvements.

The Carpenter Enamel Rheostat Company will display, in use, various types and sizes of their field regulators, theatre dimmers, motor starters, motor regulators, reversing controllers for traveling cranes and elevators, etc.; also automatic rheostats for opening circuit both from failure of current and upon overload. There will also be a full line of electrically heated tools, such as soldering irons of various sizes and for all voltages up to 500; also flatirons, curling iron heaters and other new and novel apparatus.

The Bishop Gutta Percha Company will make an exhibit, including a general assortment of their wires and cables as used in house wiring and underground work. They will also show typical, practical examples of their several styles of cables used for lighting buoys, for drawbridges on electric roads, cables and wires made for battleships, life-saving signal service, etc. They will show in addition to these gutta-percha and india-rubber, both crude and in different stages of preparation and manufacture. They will probably include also some other features of their work interesting to the public.

The Calculagraph Company will have a working section of telephone board set up in their space with which to illustrate the excellent features of their apparatus for "keeping tab" on elapsed time. There will be other features of interest and novelty.

Mr. John Burry will exhibit his improved printing telegraph system as operated by the Stock Quotation Telegraph Company in New York. The apparatus will comprise a printing telegraph transmitter of the sunflower pattern with a capacity for controlling 2,000 tickers; the relay used in connection with the transmitter, and a keyboard. The whole will be in working operation, thus giving an excellent opportunity for inspecting and studying the system.

NEW YORK STATE ELECTRIC CO.

Mr. W. H. Bonnell, the treasurer of the New York State Electric Company, of Youngstown, O., makers of incandescent lamps, informs us that they have just made the shipment to Liverpool of 1,000 lamps, being the first installment of a large order. The lamps were all shipped in one box, which the company have specially designed for their export trade. This box is made of 1¼-inch Norway pine, divided into three compartments, and so devised as to hold the lamps free from risk of breakage and to take up the least possible number of cubic inches. The case is bound outside with steel.

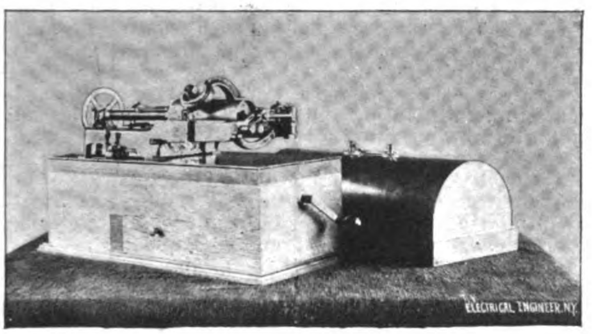
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

A NEW EDISON PHONOGRAPH.

THE recent announcement of the interesting news that Mr. Edison had bought back from the receiver of the North American Phonograph Company his own property and rights, is followed up by the placing on the market of the new Edison phonograph here illustrated. This machine is being built at the Edison Phonograph Works, at Orange, N. J., and will be handled by the National Phonograph Company, which is now establishing agencies everywhere for its sale.

The new machine conforms in a general way to the older type, but it has two decided elements of novelty. One is that it is operated by a spring motor, and the other that it is to be sold for about $40, thus placing the instrument within the reach of everybody, as a very formidable rival to the limited musical box. Mr. Edison has found that many people are still unable to avail themselves of street current for the dearer phonograph



THE NEW EDISON PHONOGRAPH.

run by electric motor, or else are very averse to bothering with primary batteries, which few of them understand. Hence, he has deemed it advisable to build this new phonograph, which is driven by a simple double spring clockwork mechanism packed away snugly under the lid of the box. The phonograph is similar in design to the standard instrument, but is in reality lighter and thus runs with less frictional loss. The thread on the main shaft is 100 to the inch, so that the standard music and recitation cylinders, of which there are now thousands, can be used. It is so arranged that multiple tubes can be employed, enabling several persons to listen at once; and it is also furnished, when desired, with a large horn and stand, answering the needs of a large audience. The size over all is 15½ by 7 inches by 10¾ inches in height. The machine is fitted with a handsome oak case, having a removable halfround top and a drawer for supplies. The whole thing is remarkably compact, and the results given by the machine are wonderful in clearness and sweetness of tone. The machine is fitted for reproducing only, but for a small extra charge it is also built to record, or to do both.

J. H. McEWEN MFG. CO.

Those who are contemplating the installation of steam and electrical apparatus should send for the handsome catalogue issued by the J. H. McEwen Manufacturing Company, Church and Cortlandt streets, New York City. This company report having recently closed contracts for the following apparatus: Two railroad generators, 150 k. w. capacity, D. C. to 12 x 23 x 36 tandem compound engine for the Hingham, Mass., Electric Railroad; one 150-kilowatt generator, D. C. to 18 x 18 simple engine, for the Morris Coal Company, Jobs, O.; one 85-kilowatt belted generator, and one 15 x 16 simple engine for the Carbondale Fuel Company, Des Moines, Ia.; one 13 x 14 simple engine for Miner-Hillard Milling Company, Miner's Mills, Pa.; one 15 x 16 simple engine for O'Neill & Patterson, Bunola, Pa.; one 16 x 16 simple engine for Ellsworth-Morris, Sutterville, Pa.; one 16 x 16 simple engine for W. J. Smith, Mount Pleasant Mines, Scranton, Pa.; one 16 x 16 simple engine, New York and Pennsylvania Company, Johnsonburg, Pa.; two 200-kilowatt generators, D. C. to 14 x 28 x 20 tandem compound engine, for Frankford & Tacony Street Railroad, Tacony, Pa.; one 10 x 10 simple engine for Charles S. Solomon & Co., St. James Hotel, Washington, D. C.; one 10 x 10 and one 12 x 12 simple engine for Dr. J. S. Gilbert, Bordentown, N. J.; one 30-kilowatt generator, D. C. to 9 x 8 simple engine, Kunkle Bros., Pittsburg, Pa.; one 8 x 10 simple engine, American Glue Company, Springdale, Pa.; one 8 x 10 simple engine, Kunkle Bros., Pittsburg facturing Company, Chicago, Ill.; one 25-kilowatt generator, D. C. to 8 x 10 engine, Lea & Carroll, Pittsburg, Pa.; one 25-kilowatt belted generator, H. W. Johns Company, New York; one 100-kilowatt belted generator, Link-Belt Machinery Company, Chicago, Ill.; one 80-kilowatt belted generator, Westinghouse Light, Heat and Power Company, York, Pa.; one 50-kilowatt generator, D. C. to 12 x 12 engine, German-American Brewing Company, Buffalo, N. Y.; one 75-kilowatt generator, D. C. to 13 x 14 simple engine, Monongahela House, Pittsburg, Pa.; one 200-kilowatt belted generator, Armour Company, Chicago, Ill.; one 60-kilowatt generator for V. Henry Rothschild & Co., for factory at Trenton, N. J.; one 120-kilowatt belted generator for Jeffrey Manufacturing Company, Columbus, O.

THE INTERNATIONAL INVENTIONS ASSOCIATION.

WE notice in "La Bourse des Brevets," published in Paris, an article announcing the fact that two companies have recently been formed, one in London and the other in Paris, under the combined name of the International Inventions Association. The object of these companies is that of examining and negotiating the sale of inventions upon a mutual basis. The Inventions Development Company, of 45 Broadway, this city, which was formed last year for a somewhat similar purpose, has recently consummated an arrangement whereby it will represent the United States, Canada and South America in a combination which appears to be very far-reaching in its scope.

The Paris company has agencies in the following cities on the European continent: St. Petersburg, Berlin, Brussels, Vienna, Zurich, Milan and Madrid.

The London company has agencies in the following cities: Bombay, Calcutta, Sydney, Melbourne, Brisbane, Cape Town and Auckland.

The New York company has agencies in Canada and South America.

We understand that the Inventions Development Company has among its stock-holders many very wealthy and prominent business men in this and other cities of the United States. The combined companies do not propose acting as patent attorneys, but intend confining their business exclusively to negotiating the sale of meritorious inventions.

The general basis of operation is that inventions submitted to any one branch of the association must pass through the branch of the company through which it emanated; thus, all the inventions submitted to the English and French companies must pass through the American company by which it is first investigated.

The general principle appears decidedly good in view of the experience and ability connected with the management and should prove not only of considerable value to inventors but turn out profitable to those connected with the undertaking.

One great advantage to purchasers of patents is that they must have passed through a most thorough examination not only by the branch of the association which first sends the patent, but all those to whom it is sent, thus forming practically a triple investigation. Patentees of meritorious inventions ought to find powerful allies in these companies.

SUNBEAM LAMPS FOR SIGNS AND DECORATIVE LIGHTING.

THE Sunbeam Incandescent Lamp Company, of Chicago, is making a specialty of lamps consuming a small amount of energy for use in sign and decorative lighting. It is claimed that these lamps not only have the advantage of the saving in energy, which in a large sign is a consideration of great importance, but that for the purpose they are superior to lamps of higher candle-power, all other things being equal. It is claimed that the effect of the glare of the lamp of larger candle-power is to blur the sign while the glow of the lamp of smaller candle-power will show the sign more clearly.

Tests have recently been made by fitting different letters of the same sign with lamps of different candle-powers and the better effect of the lamp of small candle-power has thus been fully demonstrated. A four-candle-power (20-watt) lamp is the one usually used for signs and is furnished in all voltages. The Sunbeam Company is also making a two-candle-power (10-watt) lamp in voltages from 50 to 60. These have bases to fit the standard sockets and are to be connected in multiple. The company has already filled orders received from all parts of the world, and it is claimed that there is no other lamp company that has been able to produce a lamp of such high voltage and consuming so small an amount of energy.

ELECTRIC HEAT ALARMS FOR A MAMMOTH BOSTON WAREHOUSE.

Plans have been completed for a mammoth brick storage warehouse to be erected for the Massachusetts Fireproof Storage and Warehouse Company on Bryant street, Boston. The proposed structure will be seven stories high. The foundations for this great building will be of granite, while the walls of the superstructure for the first two stories will be twenty-eight inches thick, and up to the top stories twenty inches. The estimated cost will be about $350,000 above the ground.

We learn from F. S. Palmer, general manager of the Electric Heat-Alarm Company, that a contract has just been closed to equip this property with their automatic fire alarm system. This equipment will be entirely different from anything of which we have knowledge. For instance, the regular testing and recording apparatus will be in the office, an annunciator for the various floors, and a watchman's twenty-four-hour register in series with the doors; said doors in series in the negative or blue wire. The thermostats are arranged in groups, and connected to a 70-point annunciator in the office. There will be a short-circuit box on each floor, plainly marked "Break glass in case of fire." This arrangement for the doors will be found even on the office door so the watchman, after 6 o'clock at night, cannot go out of the building without a record of the same being made in the office. He can go from the fire room to the office, and will be required to make a register of his arrival in the office and in the engine room. Should a door be opened on any of the floors, it announces the floor on the annunciator in the office; and the time said door was opened will be indicated on the 24-hour register.

This building will be entirely fireproof and should spontaneous combustion occur in any of the store rooms, it will be announced on the annunciator in the office. The watchman will then go to the floor on which the fire exists, and as he passes through the doors it will be announced in the office, and the time registered. When he gets back to the office, a test that any one can make will prove to him whether or not he has closed the doors. If the stylus punches, it proves the doors are closed. If not, it proves that he has left one open. An auxiliary test shows him on which floor he has left this door open.

In connection with this system they will have an alarm to the police station and to the fire department, by a partial underground system, so that should burglars desire to get into the building, they will have to go to a pole or a street some distance from the building, go up through numerous other wires, and cut four other wires belonging to those of the Massachusetts storage warehouse. From this pole, the wires are carried in underground conduits by the New England Telephone Co., to the building located on Bryant street.

POWER FOR THE HOGBACK TUNNEL, COLORADO.

The General Electric Company's office at Denver is furnishing the necessary electrical machinery for the construction of the tunnel through the hogback south of Pike's Peak, which is to form a portion of the new waterworks system of Colorado Springs. This enterprise is the largest ever undertaken with electricity as the motive power in the West, and among the largest in the country.

The tunnel is to be 6,400 feet long and will be run from both enus. The air compressors are to be run by a 75-horse-power three-phase motor. The generating station is to be erected a short distance above the Iron Springs Hotel at Manitou and the water necessary for the generation of the electricity is to be taken from the pipe line which now supplies Colorado Springs with water, and after being used for this purpose will be again conducted to the pipe line. The water has a fall at the site of the power station of 700 feet. The power is to be generated by a 150 kilowatt, three-phase generator, which will develop a force of 3,600 volts. The current will be transmitted about eight miles, and will be used to run the air compressors, supplying lights and for other necessary purposes.

The water for the system is to be taken from the creeks on the western slope of Pike's Peak, and will be conducted through this tunnel which will be made as small as possible, and leave room for the men to work, probably about 3 x 5 feet. The work of constructing the power station, erecting poles, stringing wires, etc., will be commenced at once, and the machinery will be shipped in about five or six weeks. The contract has been awarded to Wilson & Jackson.

MR. JOHN BONNEY, late of the Telegraph Construction and Maintenance Company, has been appointed electrical engineer in electrical charge of the Cuba Submarine Telegraph Companys lines, with headquarters at Cienfuegos.

NEW YORK NOTES.

RICKETTS & BANKS, of 104 John street, New York, after having made careful experiments, are now ready to supply the best crystalline form of tungstate of calcium for perfect fluorescence. Their material has been tested and approved by many of the most prominent workers on Röntgen ray development and has given universal satisfaction.

THE CALCULAGRAPH COMPANY have recently received orders to equip with their instruments for recording elapsed time, telephone exchanges in the following named cities and towns, viz.: Boston, Fall River, New Bedford, Brooklyn, Taunton, New Haven, Baltimore, Philadelphia, Milwaukee, Maumee, Cincinnati, Evansville, Indianapolis, Terre Haute, Altoona, Harrisburg, Hazelton, Temple, Tadmor, O., and East Onondaga.

UNDERGROUND CABLES IN TOLEDO, O.—The National Underground Cable Company has just been awarded a contract by the Toledo Traction Company, for all the underground cables to be used by the latter company during the year 1896. This contract for underground cables is one of the largest ever given out in the United States, and covers cables for several kinds of service, including railway feeder, electric light and power distribution, and when finished will be the only system in the world in which series arc circuits and the three-wire system will be distributed from the same station. The distribution will be done from one immense central station, and the sizes of cables to be used from No. 6 B & S. G. to 1,000,000 circular mils.

The contract of the National Company covers also all the work of laying and jointing and connecting of the cables and the furnishing of all apparatus to be used in connection with the underground system.

The National Conduit Manufacturing Company, the associate company of the National Underground Cable Company, furnished all the underground conduits and built the complete subway system for the Toledo Traction Company.

As a result of its continuously increasing business, the National Company's cable factories at Harrison, N. J., and conduit factories at Hastings-on-Hudson, N. Y., are compelled to run night and day to keep up with orders.

THE RUSHMORE DYNAMO WORKS, of Jersey City, N. J., report that they are fitting up the gunboats of several South American countries with their searchlights, and that inquiries are arriving from all parts of the world, in response to their announcements in the electrical papers.

NEWS ITEMS.

THE WESTINGHOUSE MACHINE COMPANY'S orders for March include three vertical cross-compound engines, each 1,600 h. p. for the Allegheny County Light Co. station, Pittsburg, Pa.

THE CUTTER ELECTRICAL & MFG. CO., 1112 Sansom street, Philadelphia, announce that they have in their printer's hands a beautifully illustrated catalogue of their C-S flush switches and accessories. This promises to be the most elaborate catalogue devoted to this subject, and will be sent post paid to all interested. They are also preparing an illustrated catalogue of the I. T. E. circuit breaker, about which we are hearing favorable comments on all sides. This will be ready early in May.

AHEARN & SOPER.—Arrangements have been made by which Messrs. Ahearn & Soper, Ottawa, Canada, will represent the exclusive sale of the Westinghouse Electric & Manufacturing Company's apparatus in the Dominion of Canada.

WURTS' LIGHTNING ARRESTERS.—Although the season has scarcely opened, the demand for Wurts' lightning arresters that is being made on the Westinghouse Electric & Manufacturing Co. bids fair to be phenomenal. How popular this lightning arrester has become, and how well it has proved its efficiency, may be gathered from the fact that during 1894 the Westinghouse company sold nine thousand arresters, and in 1895 twelve thousand, while every indication for the present year promises to double the sales of last year.

PROBATING FRANKLIN'S WILL.

The will of Benjamin Franklin was allowed in the Suffolk County, Massachusetts, Probate Court to-day by Judge Grant on petition of Mayor Quincy, of Boston, as a foreign will, having been probated a century ago in the Orphans' Court in Philadelphia. The probate of the will now is deemed necessary in view of a legal disposition of the "Franklin Fund," which was created by the will of Franklin, and now amounts to several hundred thousand dollars. There was no opposition to the probate.

Department News Items will be found in advertising pages.

Electrical Engineer.

Vol. XXI. APRIL 15, 1896. No. 415.

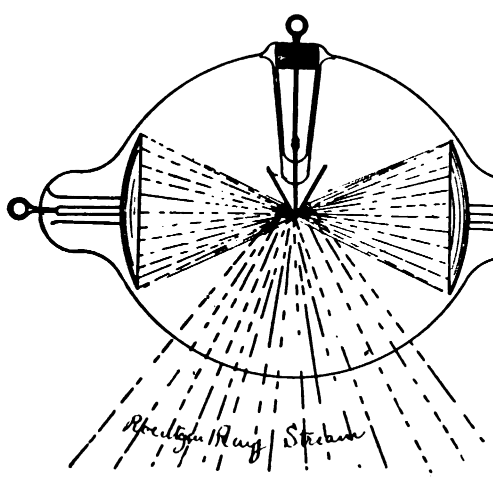
Electric Lighting.

A STANDARD FORM OF ROENTGEN RAY TUBE.

Elihu Thomson

MY attention has been called to an article by Mr. T. A. Edison on "Are Röntgen Rays Due to Sound Waves?" published in "The Electrical Engineer" of April 8. In the first place, I would say that I thoroughly appreciate the arguments advanced by Mr. Edison in relation to this matter, but if I understand him to put forward the idea that Röntgen rays are simply sound waves of very high or inaudible pitch in air, solids, gases, or liquids, then I think there are certain facts which negative any supposition of this kind. Röntgen rays traverse without apparent absorption highly exhausted bulbs, or bulbs which contain the least possible air or gas. This fact alone would point to the Röntgen ray as propagated by ether and not as a sound wave in air. It would be very difficult to explain on a sound-wave theory how some substances are electrified positively and others negatively by Röntgen rays.

If Mr. Edison means that the waves are longitudinal waves, and not transverse waves in the ether, and, therefore, analagous to sound waves, this, of course, would not be a new view, as it has been advanced by Prof. Röntgen himself, though there are many facts which have since been discovered which



PROF. ELIHU THOMSON'S STANDARD RÖNTGEN RAY TUBE.

tend to favor the idea that Röntgen rays are simply very high pitch waves similar to light waves; that is, transverse waves in the ether.

The experiments with the steel plate which Mr. Edison describes appear to me to indicate something in the nature of diffraction. Some of the earliest Röntgen pictures which I made gave evidence of a slight amount of reflection of the rays at high angles, at least the appearances presented, could only be explained on the idea of reflection. The rays found in the shadow towards the edge of the steel plate in the experiments of Mr. Edison may have been due to diffraction.

My observations in regard to the Röntgen rays from tubes with even so low a vacuum as to give striae coincide with those of Mr. Edison—that such tubes will even give Röntgen rays when subjected to very sudden discharges, that is, discharges in which the potential wave thrown upon the tube is abrupt. Hence, a Wimshurst machine will excite such a tube where an induction coil may not. The sharpness of the shadow given by a Crookes tube will depend upon the definiteness of the bombardment, that is, upon some particular spot alone becoming the source of the Röntgen rays, and upon the character of the discharge, which, if oscillatory in character will, in many tubes, produce two sources of emanation of Röntgen rays, and this, of course, will give confusion in the image. An abrupt break in the Ruhmkorff would naturally tend to give prominence to a particular direction of discharge, and, hence, conduce to making one of the terminals more entirely a cathode than with a less abrupt break in the primary, sharpness being the natural result.

I may add that the observations which have up to this time been made as to the source of the rays point to the fact that the cathode rays must strike some surface, which then becomes the Röntgen ray source. My own observations make me think that if the bombarded surface is of such a dense metal as platinum, which does not fluoresce, the rays will be more energetic. Bearing in mind these considerations and that it is desirable to possess Crookes tubes which are of standard make and adapted for use with high frequency apparatus, Ruhmkorff coils with oscillatory or uni-directional discharge, or with Wimshurst or Holtz machines, I have proposed as a standard tube one which is represented in the accompanying sketch.

The structure consists of a bulb, at opposite sides of which are mounted concave aluminum discs supported on wires sealed through the glass. The foci of these concave electrodes coincide nearly at the center of the bulb, at which point is located a V-shaped sheet of platinum, iron, or other piece of metal, such as a small piece of iridium. This could be supported in any way desired, but it may be suggested as a convenience that it be mounted on a third or middle terminal, so that it can be made an anode. In using this tube with high frequency currents the two cup-shaped terminals are attached to the source of electric currents, which alternately become cathode during the discharges, and cause the Röntgen rays to be emitted from the apex of the platinum sheet or from the surface of the piece of metal placed at the common focus. With oscillatory currents from a Ruhmkorff coil the same connections may be used, and even when the discharges are uni-directional the connection of either cup-shaped terminal as a cathode makes the tube effective, but in this case the middle terminal may be made the anode and the other or cup-shaped terminal a double cathode, and thus give the greatest amount of cathode surface, with but a short distance to be traversed by the discharges, while the sharpness of the focus, and consequently the definition obtainable with the Röntgen rays remains unimpaired. If the vacuum in such a tube is too low, it is also possible to raise it quickly by constituting the middle terminal a cathode for a time, in which case metal would be carried therefrom and deposited on the side of the bulb in a very fine state of subdivision and quickly absorb the residual gas. During the working of the tube it can sometimes be restored by simply heating the tube to a high temperature.

WAS THIS LAND LIT BY X-RAYS?

A reader of "The Electrical Engineer" sends us the following bit of folk-lore taken from the book entitled "Stray Leaves from Strange Literature," by Lafcadio Hearn: "There is in the ancient Finnish tongue a strange book written, called 'Kalewala,' a book of runes, treating about the beginning of the world, and about the god-smiths who first wrought the foundations of the sky, and about the witches and enchanters of the farthest North. Of witches Louhi was among the greatest, and her daughter was wooed by gods and heroes, even by Wainamoinen the mightiest. * * * So fair was the virgin that her beauty gave light like the moon; so white were her bones that their whiteness glimmered through the transparency of her flesh; so clear was the ivory of her bones that the marrow could be seen within them. * * * And the story of how Wainamoinen built a boat that he might sail to woo the virgin, is told in the runes of the Kalewala."

ROENTGEN RAY LAMPS AND OTHER EXPERIMENTS.

BY

Thomas A. Edison.

A VACUUM tube, the inner portion of which has fused to it crystals of tungstate of calcium when exhausted to the X-ray stage, gives out scarcely any of the rays; on the other hand, the tubes shine with a splendid white fluorescence. We have here a true fluorescent lamp, possibly commercial, as a very small bulk gave in the photometer 2½ candle power with an extremely small amount of energy. The white light is of a character not unpleasant, but quite the contrary. The spectroscope reveals the reason; the spectrum has strong red rays.

Tubes with aluminum electrodes become coated with transparent aluminum, which, as time goes on, gets so thick as to become visible. The X-ray is greatly diminished, not, I think, so much on account of absorption of the wave after generation, but through lack of elasticity, the concussive action or energy being absorbed by deforming the aluminum.

Silicon carbide is a conductor for high-tension current, a fact previously noted by Tesla. It is a very good conductor. I have substituted pieces of the carbide for aluminum; no air comes therefrom; it does not absorb air; it cannot be melted, nor does it blacken the glass. The voltage can be increased to a point where the glass melts. It may possibly prove the most practical substance for electrodes in high vacua. The only difficulty is the contact between the carbide and platinum wire.

With all glass used for making bulbs the sodium line shows in the spectroscope; there is evidently a decomposition due to the current, electrolytic or otherwise. Combustion tube glass has the least; lime soda glass, that is, the glass used for dry plate photography, has the most. This latter glass is the most transparent to the X-ray, but the continuous decomposition of the glass makes it almost impossible to maintain a vacuum except when connected to the pump, and even then the effect of the current is greater in producing gas than the capacity of the pump to exhaust, but the ray is very powerful.

Experiments were made with over twelve hundred substances in the form of crystals and precipitates. Not one fluoresces through thick cardboard when the sources of energy are the arc light, a six-inch spark in air, a vacuum tube with vacuum so high that a ten-inch spark leaves it dark, and the direct rays of the sun from 11 till 2 p. m.

Another fact supporting the theory that the X-ray is a wave due to concussion is that crystals of calcium tungstate are very sensitive to agitation or slight friction, giving off light. It is also of interest to note that by a properly arranged sensitive flame and phonographic listening tubes, my assistants have made it responsive to the X-ray.

THE DOEHN CARBON CONSUMING CELL.

A new proposal for making a galvanic cell consuming carbon was made by Dr. A. Coehn, in a communication to the Elektrotechnischer Verein of Berlin, on February 25th. The "Elektrotechnische Zeitscrift" for March 12th makes the following remarks on the subject: "The investigation is based upon a fact which has been already observed by several other electrochemists, but which has so far been found very inconvenient in electrolytical processes in which insoluble anodes are required. The carbons mostly employed have not, under the influence of the current in different liquids, shown sufficient resistance to disintegration. On the contrary, the carbons fell to pieces. In proceeding step by step and with experiments well arranged, Dr. Coehn has been able to find out the exact conditions required to enable the carbon to produce on oxidation only carbon dioxide (CO_2) and carbon monoxide (CO) on the anode. It was found that a certain temperature and a certain current density were necessary conditions, as electrolytic diluted sulphuric acid of a certain gravity was used. Dr. Coehn was further successful in depositing on the cathode the carbon given off by the anode. This proves that the carbon or a compound of it plays an important part in the transport of the electricity through this liquid. To construct a cell which is based on the combination of carbon the necessary oxygen must be supplied to the cathode. This is done by employing peroxide of lead cathode. In such a carbon cell, with dilute sulphuric acid, the carbon burns to monoxide and dioxide, while on the cathode peroxide of lead is reduced to metallic lead."

ARE ROENTGEN RAY PHENOMENA DUE TO SOUND WAVES?

BY PROF. WM. A. ANTHONY.

THE observations of Mr. Edison, recorded in his article in The Electrical Engineer of April 8, do not appear to me to warrant the conclusion at which he arrives. It is well known that sound shadows are not as sharply defined as light shadows and the reason is that the wave lengths of sound are very great compared to those of light. The shorter the wave lengths the sharper should be the shadows; that is, the less should the geometrical shadow be encroached upon by the radiant energy. Now the geometrical shadows for apparatus arranged as in Edison's Fig. 1 would be included between the lines a a′. Rays deflected into the shadow, as shown in that figure, could not have been due to a true difraction, but must have been due to some other cause.

The experiments of Le Conte, to which Mr. Edison refers, so far from warranting the conclusion that Edison draws from his own experiment seem to me to show that Edison's result could not be due to diffraction, and therefore has no bearing upon the question as to the nature of the Röntgen radiations. Le Conte's experiments show comparatively sharp sound shadows. Even at a distance of twelve feet from the pile, only one foot in diameter, casting the shadow, there was no apparent penetration within the geometrical boundary. If any such effect as Edison shows had occurred, the shadows should have been completely obliterated at one foot behind the pile.

The beautiful experiments of Professor Stine and of Scribner and M'Berty indicate a straight line propagation of the Röntgen radiations, and go far to prove that the result obtained by Edison must have been due to some other cause than that to which he ascribes it. These experiments were admirably adapted to demonstrate th source of the Röntgen rays, and led us back to the conclusion originally announced by Röntgen himself, which has always seemed to me to be the true one, notwithstanding all the different conclusions that have been drawn from later experiments. These results go to show how carefully Röntgen had studied the phenomena before making his original announcement.

These experiments seem to demonstrate conclusively that the source of the Röntgen radiations is the bombarded surface of the glass. It is probable, as suggested by Professor Elihu Thomson, that this bombardment produces two effects, one the Röntgen radiations and the other phosphorescence of glass, and that the greater the phosphorescence, the less the Röntgen rays.

I have always wondered why some of the various experimenters upon these phenomena have not made experiments to demonstrate, first, whether the Röntgen radiations are propagated as waves, or are flying particles shot off from the source, and, second, if waves, what is the wave length? If they are wave motions, whether the vibrations are longitudinal or transverse, the fact should be capable of demonstration by diffraction phenomena. Professor Snow, of the Wisconsin University, has suggested a method by which the test could be made.

A parallel beam of rays might be obtained by allowing the vibrations to pass successively through two narrow slits in lead screens placed a little distance apart. This beam being received upon a grating consisting of finer copper wires laid parallel to each other, should, if the radiations are wave motions, give diffraction phenomena that would demonstrate the fact, and also furnish data for computing the wave length, if the radiations consist of a few definite wave lengths only. The question whether those radiations are wave motions or an actual translation of particles, seems to me the most important one to be settled at this stage of the investigation, and I hope some one will take the matter up.

PROPOSED MUNICIPAL PLANT FOR UTICA, N. Y.

Professor E. P. Roberts has estimated $114,000 as the cost of a municipal plant for Utica, to furnish 500 arc lights. Mr. M. H. Johnson, a local electrical engineer, has estimated $161,441. The assumed operating expenses are respectively $39,930 and $44,996.

"We desire to compliment you on the excellent number of The Electrical Engineer which we had occasion to examine in connection with our article on Edison's Experimental Researches on the Röntgen rays."—Houston & Kennelly.

CANDLE POWER OF THE X-RAYS.

BY EDWARD P. THOMPSON.

I USED the following method in order to obtain a rough idea as to the strength of the Röntgen rays as compared with those of a canule. The process, of course, will not give the true candle-power, for the simple reason that the X-rays are not visible, but nevertheless, what may be termed the equivalent of the candle-power may be measured, so that the result impresses one with the extreme weakness of the rays in one sense, although they have so great a penetrating power.

In order to obtain the best results roughly, I receded from the Crookes' tube while looking into the skiascope, until the luminosity disappeared, and then measured the distance between the screen and the Crookes tube. It was about six feet. This represents about the usual power of X-rays, except in Tesla's results where he obtains fluorescence of calcic tungstate at 40 feet. Of course, the luminous rays of the Crookes tube were extinguished by the double thickness of black paper between it and the fluorescent screen.

I then held the skiascope (the name suggested by Prof. Magie, and which I think is by far the best) so as to face the candle, and I walked away from the same until the luminosity of the screen disappeared. The distance was likewise measured. In this case there should be no opaque substance between the candle and the screen. When it is between the Crookes tube and the screen, it has practically no effect upon the X-rays, whereas it would cut off all the rays from the candle. The distance in the latter case was about 120 feet. If the power of X-rays varies inversely as the square of the distance, a candle is 400 times more powerful in producing fluorescence than the X-rays, particularly from a Crookes tube that I employed and charged with the particular apparatus. In the same manner the candle-power of the X-rays from any Crookes tube could be measured.

It is assumed that the fluorescent screen represented the total energy for producing fluorescence as far as the X-rays were concerned. However, the candle rays are not all converted into fluorescent light; for those below the green, including yellow, orange, red and infra-red rays, produce no luminosity upon the fluorescent screen; therefore this method does not compare all the energy of the X-rays with the energy of the candle rays, but it serves to give a rough comparison. It is assumed that the fluorescent screen converted all the ultra-violet rays, violet, indigo, blue and green rays into luminous rays. This assumption may cause unknown errors in the result.

Neither would a corresponding photographic method be exact, because the silver compound would not be chemically acted upon by the infra-red rays. It should be noticed also that both methods are based upon the assumption that all the rays in both cases are converted into green rays of light by means of the fluorescent screen and into chemical energy by the photographic plate.

It remains a fact, however, that as far as we are able to transform the energies, the X-rays are weak as compared with those from the candle. Both will produce fluorescence and chemical action, but the candle very much more powerfully than the X-rays. When the two sets of rays are compared on other grounds, the Röntgen rays are more powerful, as, for for example, in reducing the sparking distance either for a positively or negatively charged insulated plate. Again, from another point of view, the candle rays can be turned out of their course by reflection or refraction. It still remains true, however, in the rough, that inasmuch as fluorescence and chemical action are both produced by the two forms of energy, therefore, these phenomena serve as a standard upon which to operate in order to obtain what may properly be called candle-power, with the restriction that it is not the true candle-power, because things of exactly the same nature are not compared. In the case of the candle-power of the sun, arc light, oxy-hydrogen flame, the incandescent lamp, gas flame, etc., their natures are the same as that of the candle, namely, all have all the luminous rays of the spectrum, but some more than others, so that in these cases we are comparing the rays of similar natures.

THE PHOTOGRAPHIC TIMES for April is as usual interesting to photographers in its reading matter and illustrations. It contains some further illustrations of cathodographs and quotes The Electrical Engineer's announcement of the discovery of J. G. Vine. This magazine has been including in its pages since January an "Encyclopaedic Dictionary of Photography," of value to photographers, and the announcement is made that by the end of this month back numbers of the "Times" containing this dictionary cannot be supplied to intending subscribers.

IS A GLOWWORM RESPONSIVE TO ROENTGEN RAYS?

BY WILLIAM MAVER, JR.

IT has long been a saying among scientists that if the secret of the glow-worm were known we should have at once the most economical of all methods of illumination. I am going to hazard the proposition that Röntgen has, perhaps, discovered it. But, of course, in order to bear out the proposition we must assume that the glow-worm has in its body the necessary fluorescent substance, and that it either possesses the mechanism within its own frame for establishing the X-rays, or two other things must or may be: (a) The X-rays are constantly present everywhere but in a very attenuated form, so to speak, and (b) the fluorescing material in the glow-worm is so exceedingly sensitive to the rays that it responds to them, attenuated as they may be. The glow-worm, it appears, has the power of producing luminescence at will. If this is so, then, taking into consideration the fact that the luminosity of phosphorescent animals is known to remain after the animal is dead, it would appear that the hypothesis that the phosphorescence is due to a material exceedingly sensitive to the assumed, ever present, but very attenuated X-rays, is the correct one, rather than that the glow-worm and other phosphorescent animals have the power within themselves to set up X-rays. The fact that the glow-worm has the power to produce the fluorescence at will may be accounted for by assuming that it has the power to change the chemical form of the fluorescing material at will. I have in mind, in advancing the hypothesis, that the phosphorescing substance of, so called, phosphorescent animals is extremely sensitive to X-rays, an analogous effect, for instance, to that of the sensitive ear of some animals which can detect sound waves that are inaudible to the human ear.

It may be that all of the foregoing may be unsound, and it may be that it is already trite. But as to the latter, in view of the fact that I am a conscientious reader of the electrical press, I feel justified in doubting it.

EXHAUST STEAM HEATING FROM CENTRAL STATIONS

BY I. H. BABCOCK.

LIGHTING and power stations with extensive boiler capacity have brought in new conditions to deal with. Electric lighting companies are competitors with the gas companies, with their well-established business principles of saving and turning all waste products into money. Is it not reasonable to believe that the electric companies will have to pursue the same policy if they are to succeed? At present, where they have not adopted exhaust steam-heating, an electric station is blowing nearly nine-tenths of its fuel through the exhaust pipe. How to save this and convert it into money is the important problem to solve. Some companies have already arrived at a solution by laying underground steam mains and selling steam for heat to the same customers to whom they supply light. They find that all station expenses, that is, their entire fuel bill, their water rents and labor account in the boiler house can be paid entirely from the sale of exhaust steam, so tnat the electric current can be put on the wires free from cost. This gives continuous service for boilers and men, instead of their lying idle a large share of the twenty-four hours. Will this not help out many of the electric companies that are having a hard row to hoe?

Some station managers fear the effect of back pressure upon their engines; this fear is practically groundless. One railway and lighting company that I have in mind is heating over 10,000,000 cubic feet of space with exhaust steam. In the coldest weather the back pressure is not over 3 or 4 pounds, and ordinarily not more than one pound. Their engineer says the engines work with more satisfaction against moderate back pressure than when there is none. With proper sizes of mains for the work to be done, and steam delivered free from entrained water, there will be no difficulty on account of back pressure on engines. The vacuum principle is in force in every building taking steam; the radiators are condensers and as the steam gives off its heat and is converted into water, fresh steam rushes in to supply the threatened vacuum through the service pipes from the mains, so that very little forcing is required if only the pipes are of proper capacity.

If this subject were thoroughly understood by projectors of electric enterprises, whether for railway or lighting purposes, stations would be located with a view to supplying heat as well as light and transportation to customers, from the very start. Happily it is not difficult now for existing plants, in most cases, to make this addition to their present business, and where this has been done, the heating part of the enterprise is looked upon as of equal importance with the primary object.

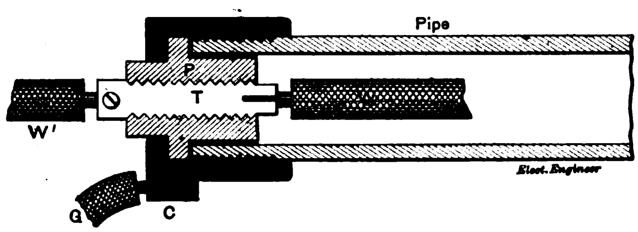
CONCENTRIC WIRING.

BY A. E. DOBBS.

In my last article on the subject of plain iron pipe for conduit, my object was to show how a plain iron pipe could be substituted for the present iron armored conduit. This is as much of a concession as we can expect from the National Board of Fire Underwriters at the present time.

Now for the future I propose a concentric wiring system which may some day become practicable, though many electrical experts will no doubt disagree with me, and the object in view is not so much to suggest brilliant or original ideas as to formulate practical, working details of such a system.

Many of us who have been in the business for years do not feel satisfied with wiring methods now in use. The Interior Conduit people have shown us a great deal of what may be, but still we are not satisfied. Details of construction have not received the care, attention and thought that is given to dynamo and motor design, due possibly to the fact that if a machine is not correctly built there will be trouble right away, while wires can be strung in a building in almost any manner and make no trouble for years, and when they do, the building is simply rewired, or electricity abandoned. Some of us think that wiring methods could be greatly simplified by the use of plain iron pipe with a single wire drawn into it, as suggested by the recent interesting article by Mr. Mavor which appeared recently in "The Electrical Engineer." We find, first, that Mr. C. J. Kintner holds a patent on this method of wiring, but without regard to anybody's patents we can work out a system of details and leave patent questions to be settled in some other way, hoping to suggest a method that will



OUTLET FOR CONCENTRIC WIRING SYSTEM.

meet the approval of the insurance interests, if anybody should wish to install such a system.

On the other side of the water we find the Phoenix (English) rules on this subject as follows:

Concentric Conductors, No. 25.—"Concentric conductors will be allowed under those circumstances and in those places for which permission has first been obtained and when the particular system and design proposed has previously been approved. All joints and connections must be so made that freedom from undue heating would be absolutely secured, and the outer conductor must be so securely protected that all danger from injury, corrosion, or other causes (electrical or otherwise) would be effectually prevented; the precautions taken must be such that it would be impossible for the conductors to be affected by moisture. The whole of the work must be done to the satisfaction of the technical officer of the fire office."

Foot notes accompanying this rule are as follows:

"The insulation resistance between the internal wire and the return of a concentric conductor before being placed up should not be less than 250 megohms per mile; the electromotive force of the current not exceeding 210 volts.

"The internal wire should be positive if possible. It must be insulated to the satisfaction of the technical officer of the fire office in accordance with Rule 4. The insulation must be impervious to moisture and of approved thickness. This insulation should have two approved metallic envelopes, the first one forming the return conductor, the second one forming the 'guard;' these, except when the system is earthed, must be insulated from each other. The 'guard' must be an absolutely efficient protection against mechanical injury taking place to the return conductor, and also an efficient protection against any accession of moisture to the insulation, especially where the system is earthed.

"The carrying capacity of the conductors must be at least equal to the ratio of that laid down for copper in Rule 2; if, however, a metal other than copper be used, the specific resistance of which is greater than that of copper, then the sectional areas of the conductors must be proportionally increased.

"No metal, however, will be allowed to be used for the conductors that does not meet the approval of the technical officer of the fire office; the thickness, also, of the metallic envelopes forming the return and the 'guard' must be to his satisfaction. * * *

"If the system be earthed, then the earthing must be done to the satisfaction of the technical officer of the fire office, but no earth connection will be allowed to a gas pipe, lead or composition pipes. If any part of a concentric system be earthed, then the whole system must be concentric, unless permission to the contrary be given.

"Switches and cut-outs should always act on the internal (or live wire) when the system is earthed."

There are some absurdities in the above rules, to an American at least. First, what is the use of concentric conductors if the outer conductor must be insulated? However, they modify this in a later clause concerning the earthing of the whole system, but leave the whole matter to the discretion of the fire officer, who, it is to be presumed, is more intelligent than a certain inspector I know who required all brass-armored conduit on a brick wall to be cased in wooden boxing, for did not the rules say an "insulated conduit"? The system I have in mind is an iron pipe, which is run on the loop system to outlets and junction boxes the same as any other conduit system. The joints are united by couplings through some metallic compound, or it might be the plastic material which has been so successful in the bonding of railroad tracks so that the resistance of the couplings would be practically negligible; 1,000 feet of one-quarter-inch gas pipe would have a resistance of about 1 ohm, which would surely not be objectionable, as it would be a very exceptional case where such small pipe would have to go further than 200 feet. A ⅜-inch pipe would reduce the resistance of the outer conductor to .7 ohm per thousand feet, which would be still more desirable. This is on the assumption that the material already spoken of makes the resistance of the joints very low. Close-fitting brass couplings might also help us out in this matter and perhaps a set screw in the coupling would be desirable. All this is ordinary gas pipe into which a No. 12 or 14 wire has been drawn, the pipe itself being grounded.

In Fig. 1 is shown a method of bringing the wire out of and into the pipe at fixtures and junctions; T is a lug into which the wire, W, in the pipe soldered; this screws into a porcelain bushing, P, which projects through and is held in place by a cap, C, through which the porcelain bushing projects. The lug, T, may then be connected to the fixture wire, either by a screw or solder.

In combination fixtures the wires, W and G, could be taken down through the fixture, which, of course, could not be connected to the wiring conduit, but in simple electric fixtures a reducing nipple would take the place of the cap, C, and the wire, W', carried right down through the fixture, while the extra wire, G, would not be needed.

On such a system the pipe would be well grounded and all switches and cut-outs would be single pole—another great saving.

Another plan I have sometimes thought of is to have the pipe insulated on the inside, and to pull in bare wire, adopt wire of a certain size as the standard, say, No. 15 B. & S. One of these wires would carry 9 amperes, the limit usually run on a single branch circuit. Two of these wires would be equal to No. 12 single wire, three to No. 10, five to No. 8, and so on down. This would oblige the contractor to carry only one size of wire in stock, the No. 15 bare copper, from which he could make up any desired size of conductor; but, as Mr. Mavor has pointed out, the size of the internal conductors need not be so large, as the resistance of the pipe would be very law.

The objection to this plan would be that in case of a short circuit nothing but covered wire could ever be pulled in afterward; another trouble would be to get an insulation for the inside of the pipe. Paper tubing absorbs moisture; Vulca tubing is brittle, and rubber decays. Porcelain, if made in short lengths and fitted into the tube, might do, but we fear that it would be expensive, and it would allow of but very little pipe bending, but it would prevent short circuits. If any one should invent a flexible glass tubing which was talked of five years ago the whole conduit problem would be easily solved. If any one wants to try this system there is only one way to do; that is, to lay out the entire system in this manner, whether an isolated plant or a town. I do not think a mixed system would answer. It certainly would not do in cities like New York on account of electrolysis; but where the entire system, as in the Edison system, has a grounded neutral which should carry current to the farthest end with not more than 5 per cent loss, such a system should be successful. Of course the insurance people would have to be consulted as to every detail of this plan.

THE ELECTRIC LIGHTING OF ISLINGTON, LONDON.

The Buildings and Plant.—The chief motives which governed the architect (Mr. A. Hessell Tiltman, F. R. I. B. A., who had previously carried out important work for the Vestry, including the splendid baths and wash houses), in conjunction with the electrical engineer, in planning the buildings may be briefly stated as follows: 1. Considerable provision for future extension of the engine and boiler houses at a minimum cost. 2. A full complement of offices, stores, workshops, etc., to meet all future requirements. 3. Special facilities for the delivery and handling of the coal with a minimum of labor. 4. A system of gangways and railway that should govern the easy delivery and removal of heavy goods to and from all parts of the establishment. 5. The separation of the public offices from the engineering department. 6. Light, lofty, and well ventilated rooms, for the health, convenience and comfort of the staff. 7. Mode of finish both internally and externally that should assist the economy of administration by the avoidance of the necessity for periodical repair.

Main Entrance.—The principal and public entrance is situated at the corner of Eden Grove and Grove street. The front elevation is of salt-glazed brick, and is surmounted with a cupola.

A door leads into the timekeeper's office from the street direct, and also forms a private entrance into the works.

The entrance hall, which is faced with cream glazed brick, is shut off from the street by means of ornamental collapsible gates, and from the works by large wood doors. On the left of the entrance hall is a door communicating with a stone staircase which leads to the offices above. At the top of the staircase on the right is the public waiting room, adjoining the public office. Behind the waiting room and through a private door is a corridor leading to the drawing office and the chief engineer's private office. (See plan, Fig. 1.)

On leaving the waiting room, and passing through the swing doors on the right will be found a corridor leading to the assistant engineer's office and the clerks' lavatories. Here another pair of swing doors separates the commercial and the technical departments. Past the swing doors is the photometer room, which is equipped with a photometer and other apparatus (by Messrs. Elliott Bros.) for testing the candle-power, durability, and efficiency of various lamps.

At the end of the corridor on the right is the testing room, which contains a fine set of apparatus for making insulation, copper resistance, and capacity tests, and is used for testing the street mains as well as the alternators, transformers, and other apparatus. Kilowatt and deka-ampere balances, and other standardizing instruments are also provided, as well as a full complement of instruments, resistances, etc., for meter testing and other purposes.

A steel trap in the floor and a girder above permit of converters or other apparatus being hauled from the trucks or wagons below up into the testing room.

Adjoining the testing room is the arc lamp room, where all arc lamps are tested and regulated before being erected in the streets. In this room also is provided a trap in the floor and girder for unloading goods.

Next to this room are the oil stores, containing the oil tanks for engine, dynamo, and cylinder oil. These are of sufficient capacity to hold 1,000 gallons, 1,000 gallons, and 500 gallons, respectively. Directly below the oil stores, in the gangway, is a Worthington pump, by means of which the oil is pumped direct from the barrels in the trucks or wagons up into the tanks without unloading the barrels, after which the empties are returned in the same truck, a considerable saving in labor being thus effected.

Beyond the oil stores is an open area required by the building act. The door on the opposite side of the bridge, and directly facing it, leads to the back of the switchboard, while that on the right leads to the switchroom. This is an exceptionally fine room for the purpose, it being forty feet long, twelve feet wide, and twelve feet high. The floor is covered entirely with rubber mats, for the protection of the attendants and for cleanliness. The room directly overlooks the engine house, of which it forms a part, and communicates with it by means of a balcony and two iron staircases.

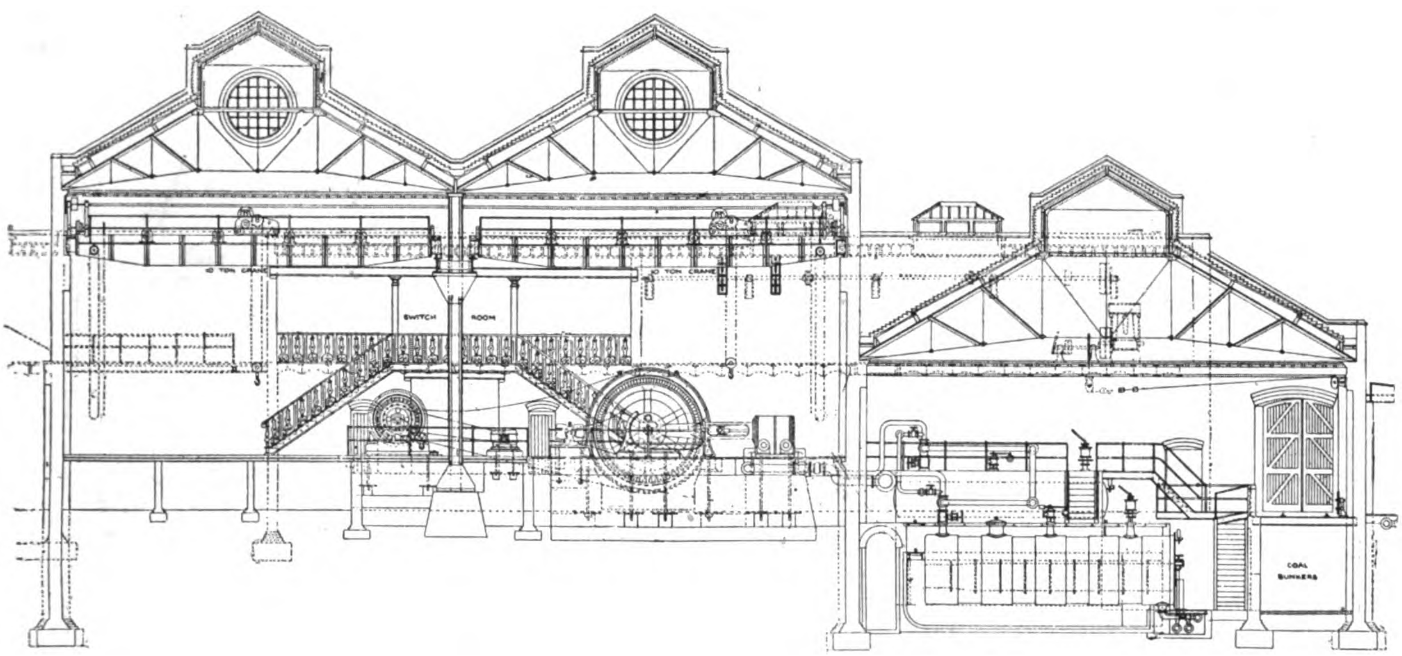


FIG. 1.—ISLINGTON ELECTRIC LIGHT STATION. SECTIONAL VIEW.

The ship's telegraph which stands on the balcony is used for signalling to the engine drivers, it being connected with a large dial fixed on the wall of the engine room directly facing the engines.

From the workshop a flight of stone steps leads down to the gangway. In this gangway, and almost underneath the steps, is a recording weighbridge by Messrs. Avery & Co. This is used for weighing the trucks of coal before they are unloaded into the coal-bunkers. A little farther on the right is an iron door leading to the boiler house. This is a fine building 109 feet in length, 56 feet in width, and 49 feet in height. For the sake of cleanliness and light, the walls (except for the temporary end wall and the interior of the coal-bunkers) are faced throughout with ivory glazed brick.

The ground has been excavated to a depth of eleven feet below the railway level. Large doors communicate with the Great Northern Railway, a private siding being brought right up to the turntable which is situated close to the doors on the outside. From the turntable a railway extends the full length of the boiler house and directly above the coal-bunkers. The loaded coal trucks are hauled into position over the bunkers by means of the traveling winch, which is driven by endless ropes from the engine in the fitting shop. Here the trucks are up-ended by means of the winch, and the coal shot directly into the bunkers below and close to the furnaces, thus saving the heavy charges for labor consequent upon the ordinary methods of delivering and unloading.

From the far end of the boiler house springs a large chimney shaft, which rises to a height of 180 feet. Its internal diameter at the base is 14 feet by 14 feet, and at the top 12 feet by 12 feet; externally it is 24 feet diameter at the bottom and 14 feet 3 inches at the top. It is capable of carrying off

the gases from sixteen boilers similar to those already fixed. The foundation of the shaft consists of a block of Portland cement concrete 9 feet thick and 40 feet square. It may be here mentioned, as a proof of the excellence of the work, material, and design, that not the smallest settlement has occurred.

At the present time the boiler house contains six boilers, each capable of evaporating 5,000 lbs. of water per hour with natural draught. The two water-tube boilers by Messrs. Babcock & Wilcox, Ltd., for quick steaming, are provided in order to meet sudden demands during foggy weather. They are constructed for a pressure of 150 lbs. per square inch, are of mild steel throughout, and possess all the latest improvements—including a slight alteration in design which enables the interior of the outside vertical tubes to be properly inspected; and instead of the "headers" being of cast iron, they are of pressed mild steel, and so arranged that any tube can be readily withdrawn.

The value of these improvements can only be properly appreciated by those who have had experience of the earlier types. A full set of fittings and duplicate feed-water valves and pipes are attached to each boiler.

The four Lancashire boilers by Messrs. Daniel Adamson & Co. are of the latest type and of first-class workmanship.

They are each 28 feet long by 7 feet and 6 inches in diameter, and suitable for a working pressure of 150 lbs. per square inch.

The fittings on all six boilers are by Messrs. J. Hopkinson & Co., Ltd., while Meldrum's furnaces and forced draught apparatus are attached to each boiler. The damper gear, which is of a special character, consists of horizontal steel shafts and mitre wheels connected direct to the dampers. A locking lever and indicator on either side of each boiler enables the stoker to see at a glance the exact position of each damper. This apparatus, which was supplied by Messrs. Adamson, is a great improvement upon the old-fashioned chain and balance weight.

The side walls of each boiler are separated from those of its neighbor by an air space of three inches, so that when any boiler is being cleaned it may be cooled down sufficiently to be handled without discomfort.

In order to prevent any boiler from "lagging" and so throwing extra work upon its neighbors, an isolating valve is attached to the main valve of each. Should the pressure in any boiler fall below that of the range, the valve closes and the steam gauge indicates a lower pressure.

Isolating or back-pressure valves are also attached to the blow-off valves, thus preventing "live" steam being admitted into a boiler when off for cleaning, a necessary precaution for the safety of the men working inside.

Steam Pipes.—The arrangement of steam pipes, which was designed by the electrical engineer, provides all the advantages of a steam ring, and at the same time avoids many of its disadvantages. Each engine is connected direct to the main valve of a boiler, and also to an auxiliary or equalizing pipe through a second valve. When all valves are open and the engines and boilers connected to them are in operation, no steam passes through the auxiliary pipe, provided the engines are all equally loaded, each engine being supplied by its own boiler. If the engines are unequally loaded, steam will pass along the pipe from the boilers connected to the "light" engines and assist the boilers connected to the "loaded" engines. Should the boiler connected to any engine be shut down for cleaning or any other purpose, steam to that engine will be supplied from all the other boilers along the auxiliary pipe.

The chief advantages of this arrangement over the "ring" main are:

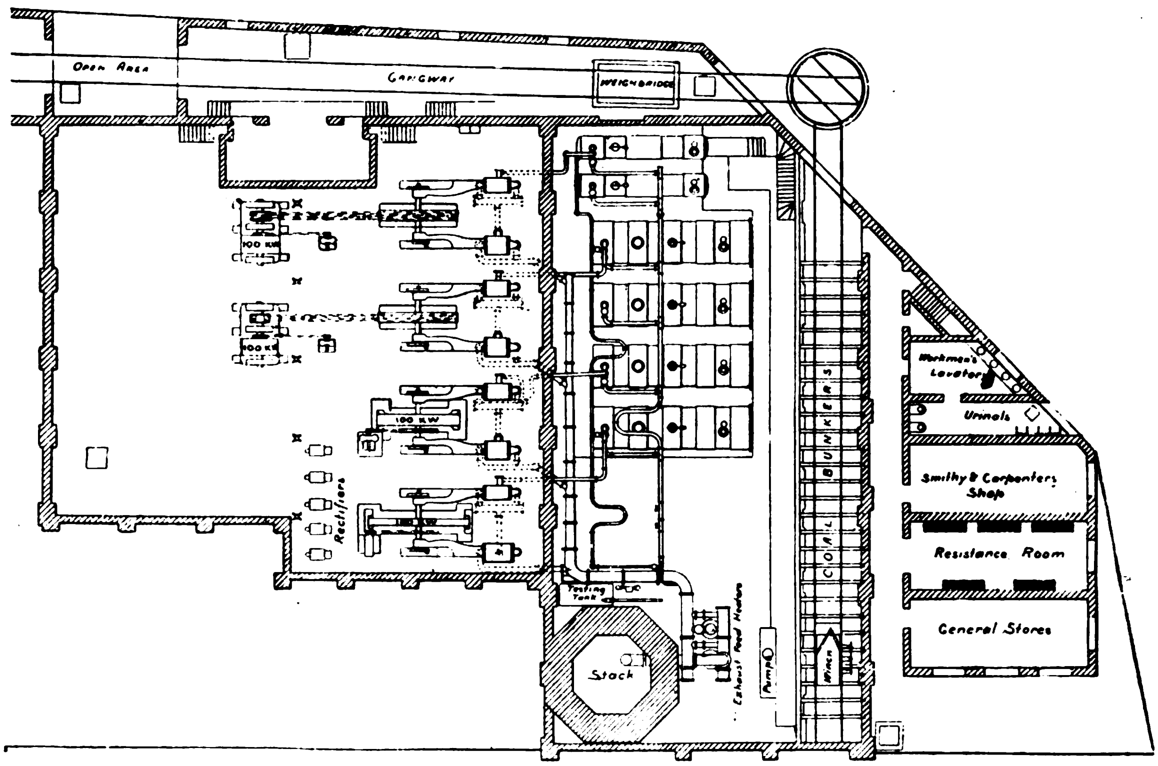

Fig. 2.—Islington Electric Light Station. Plan View.

(1) Much less pipe required and much smaller in diameter, and therefore less radiation, and fewer joints and valves; (2) Much less risk of fracture, or of leaky joints, with small pipes; (3) On light loads the range can, if advisable, be shut off entirely and the engine supplied direct from its boiler, thus saving all radiation except that due to the short connecting pipe and the engine and boiler; (4) In the event of accident to the pipes, they can be shut off, and each engine can then be supplied from a separate boiler.

All the valves are provided with "by-passes" for warming the pipes slowly. A door over the coal-bunkers leads to the messroom, where the workmen can cook their food, all appliances for the purpose being supplied. Tables, chairs, lockers, etc., are also provided for their convenience. Below the messroom is the changing room and lavatories, and adjoining are the general stores, smithy, etc. Above the stores and smithy are two large water tanks for supplying the boilers. Each tank is capable of holding 21,000 gallons. Separate supply pipes are carried to the boiler house, and they are so arranged that either tank can supply either pipe or both.

On returning through the boiler house and entering the gangway, a projecting platform will be seen which is reached by two short flights of stone steps. This platform projects from the engine house, from which it is separated by means of a steel rolling shutter. Trucks containing machinery or other plant intended for the engine room are unloaded here. Beyond the iron shutter is the engine house, a very fine building 88 feet wide, 80 feet long, and 47 feet high from the floor level.

The roof, which is arranged in the form of a double gable, is supported in the center by five steel stanchions, each capable of bearing a safe load of 75 tons. All the walls, with the exception of the temporary walls (at the end), are faced with ivory glazed brick, ornamented with red salt-glazed bricks, a dado of the latter running around behind the engines and along the walls adjoining. Two heavy traveling cranes span the building, each capable of lifting and carrying ten tons. They are driven by means of endless ropes from the engine in the fitters' shop, but they can also be used as hand cranes if required. The motion is given by means of worm-gearing, thus preventing the possibility of the load slipping, the "lowering" having to be effected by the gear instead of by a brake, which is a fruitful source of accident.

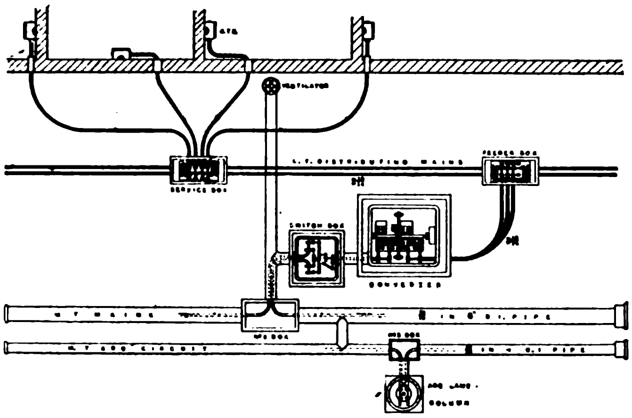

FIG. 3.—CONNECTIONS OF MAINS, CONVERTERS, ETC.

The engines, of which there are four (by Messrs. Daniel Adamson & Co.), are of the horizontal, high-pressure, compound, non-condensing type, with cylinders arranged side by side, the high-pressure cylinder being 15 inches in diameter, and the low-pressure 24 inches; the stroke is three feet. The engines run at 95 revolutions per minute, thus giving a piston speed of 570 feet per minute. Both the cylinders are steam jacketed with high-pressure steam direct from the boilers, the jackets being coupled with suitable valves and connections to an automatic steam trap. The engines will indicate 250 horsepower each at a pressure of 150 lbs. at the cylinder.

Two of the engines are rope driving, the flywheels being 14 feet diameter, and grooved on the rim for ten ropes each of 1¼ inches diameter. The other two engines drive the alternators direct on the shaft.

The Alternators.—There are four alternators, each having a safe working capacity of 125 kilowatts at a pressure of 2,000 volts, the frequency being fifty complete periods per second.

Three of the machines, viz., one direct-driven and two rope-driven, are of the "Hall" type, and were made by Messrs. John Fowler & Co.; the fourth is a direct-driven machine by Messrs. Ferranti. The rope-driven machines run at a speed of 375 revolutions per minute, the field magnets (which are laminated) forming the rotating part. The armature core is built up in sections, each section with the coil attached being removable without dismantling the other parts of the machine.

The guaranteed commercial efficiency of the alternators is 92 per cent. The Fowler direct-driven alternator is similar in type, the magnets being laminated and mounted on the flywheel of the engine. The diameter of the magnet flywheel is about 12 feet, the overall diameter of the armature casting being 14 feet.

Ferranti Alternator.—The Ferranti alternator is of the same type as those erected by Messrs. S. Z. de Ferranti at Portsmouth and Southport, where they have given great satisfaction.

Rectifiers.—There are five rectifiers, Fig. 4, used for the purpose of supplying the street lamps. These were made by Messrs. S. Z. de Ferranti & Co., and their duty is to transform the alternating current into a pulsating current continuous in direction. Four rectifiers are in use, a fifth being held in reserve.

Each rectifier is complete with constant current transformer, switch gear, etc., and is capable of supplying thirty arc lamps of twelve amperes each, or a total of 120 lamps exclusive of the reserve plant.

Similar rectifiers are successfully doing public lighting at Portsmouth, Tunbridge Wells, Cardiff, and other places.

The present engine house is capable of accommodating seven engines similar to those now fixed; and by removing the temporary walls at the end and extending the building to the boundary of the Vestry's property at present acquired, further accommodation for nine similar engines can be made. Leaving the engine house, and turning to the left in the main gangway, there will be found two large doors opening on a piece of open ground. This is the site of a future boiler house, similar in size to the existing one. The footings of the walls are thirteen feet below the railway level. All that remains to be done is to excavate the ground and erect the roof and end wall. Eight boilers can then be accommodated here, while provision has been made to duplicate the arrangements now existing in the present boiler house; and, as will be seen, the railway has already been brought to the door and a turntable provided.

Mains.—The high-tension mains consist of concentric steel-armored cable, heavily insulated with pure and vulcanized rubber and protected with braiding. The two layers of steel tape armoring are covered with two layers of heavy braiding and perservative compound. The insulation resistance from core to outer is 5,000 megohms per mile, and from outer to earth 2,500 megohms, tested in water after twenty-four hours' immersion at a temperature of 60° Fahrenheit and after one minute's electrification. The outer conductor is earthed at the switchboard. The cables, which were manufactured by the Indiarubber, Gutta Percha and Telegraph Works Company, Ltd., are drawn through six-inch cast-iron pipes, which are provided with inspection boxes at intervals of about 100 yards. At the corners of every street en route large square boxes are provided for future extensions.

Two "ring" mains have at present been laid along the compulsory area (see Fig. 3), and at intervals switchboxes have been inserted enabling any section to be cut out for testing or other purposes without interfering with the remainder.

Street box transformers are laid where required, and are connected on the high-tension side direct to the mains without joints, sufficient slack being left in the inspection boxes for the purpose. The secondary of each transformer is connected to a low-tension service box which is inserted in the low-tension mains. These low-tension mains are only laid where there are customers, and service boxes are inserted at intervals of about twenty-five yards. From the service boxes the various service lines pass to the consumers' terminals, and any consumer can be disconnected at the service boxes for the purpose of testing, etc.

The low-tension mains and services consist of concentric steel-armored cable insulated with pure and vulcanized rubber and heavily braided both over the rubber and outside the armoring. The insulation resistance is 600 megohms per mile between core and outer, and 300 megohms between outer and earth. The cables are laid direct in the ground.

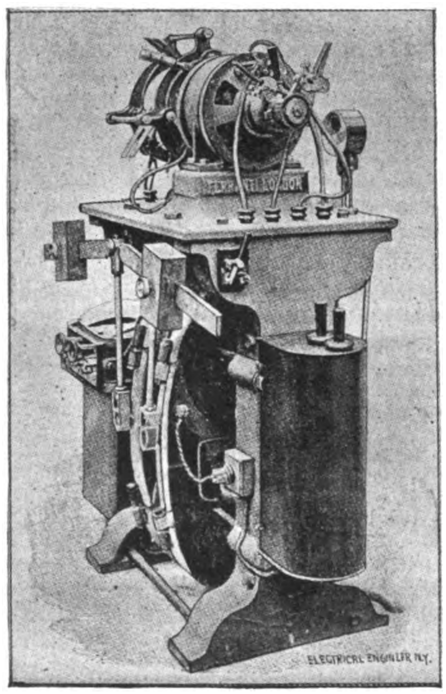

FIG. 4.—THE FERRANTI RECTIFIER.

The arc lighting mains consist of concentric steel-armored cable drawn through four-inch cast-iron pipes. The insulation and quality are the same as that used for the alternating high-tension mains before described. Inspection boxes are laid at

the foot of every lamp column, and the mains are carried up to the switch in each column without joint.

There are at present fourteen miles of cast-iron pipes laid in the district, and both pipes and boxes were supplied by the British Insulated Wire Company.

Transformers.—The transformers, which were supplied by Messrs. S. Z. de Ferranti, Ltd., are placed in suitable positions in the footways in iron boxes or chambers which are sufficiently large for a transformer of any size up to twenty kilowatts, this being the largest size allowed by the Board of Trade under the Vestry's Provisional Order.

Street Lamps.—The street lamps are of the Crompton-Pochin type, by Messrs. Crompton & Co., of Chelmsford, and are mounted on the top of handsome iron columns. The "crutches" carrying the lamps are supported on hinges, so that by releasing a catch the top of the crutch falls forward, where it is held by a chain. This throws the lamp out beyond the lamp column, and enables the globe to be removed for cleaning and trimming.

The lamp columns, which were made by Messrs. Walter Macfarlane & Co., are mounted by means of removable steel steps, which are inserted in holes in the columns provided for the purpose.

Ventilation.—In order to prevent as far as possible the accumulation of gas in the street conduits and boxes, they are connected throughout the district with the hollow lamp columns, while at frequent intervals ventilators on a level with the footpath are connected with the pipe system. It is hoped that this will prevent the accumulation and possible explosion of gas in the conduits which has given so much trouble in some districts.

Method of charging for electric energy.—Current is supplied to private customers through Hookham patent electricity meters, and is charged for on the well-known Brighton system, Wright's demand indicators being used for recording the maximum demand. The scale of charges has been arranged as follows: For the first two hours' consumption per day of the maximum demand the full price will be charged, viz., 7d. per unit; for the third hour's consumption, as above, 6d. per unit; for the third and fourth hours' consumption, 5d. per unit; for any further consumption, 4d. per unit.

We are indebted to several of our London contemporaries for the accompanying engravings.

A GOVERNMENT INQUIRY ON MUNICIPAL LIGHTING PLANTS.

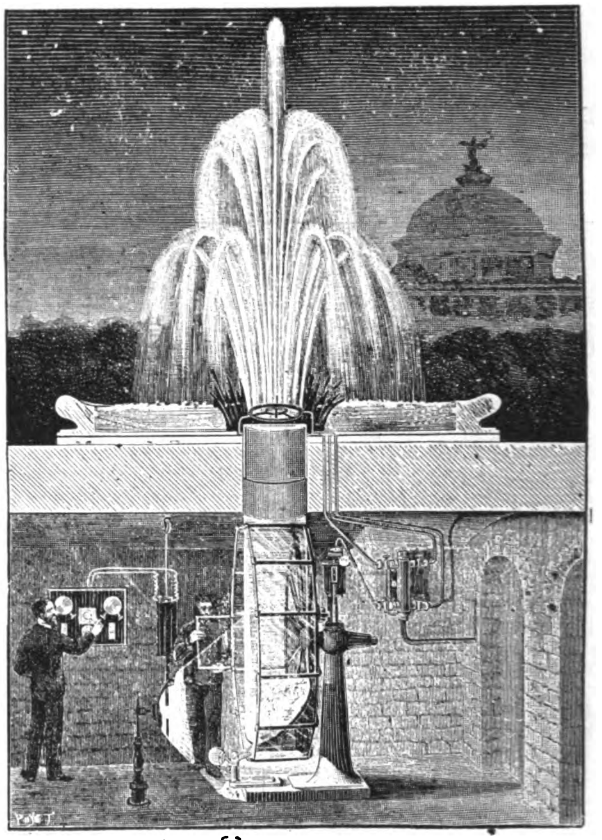
The subject of municipal ownership of gas and electric-light plants is proposed as a subject for joint investigation by the National Department of Labor and the Bureaus of Labor Statistics in the several States, the agents of the National Bureau to confine their inquiries to States which have no bureaus of statistics. The inquiry will be made in all cases upon uniform blanks and according to uniform methods. This will add greatly to the value of results and their convenience for investigators, because it will make it possible to make easy and exact comparisons. Every electric and gas-lighting plant in the United States which is owned by the municipality will be reported upon, and a sufficient number of private establishments will be included to afford a basis of comparison between the two classes. The mere difference in price of lighting is often relied upon in these controversies to decide the merits of the two systems, but many other elements will be considered in the proposed inquiry. Full statistics of the cost of plant, the interest on plant, the cost of materials, the wages paid, the cost of superintendence, and the quality of lighting furnished will be given. The balance sheet for public and private establishments, indicating whether the public establishments pay a real profit, make up a deficiency from taxation, or pay a nominal profit by ignoring the cost of plant and bonded indebtedness incurred for its establishment, will be presented in each case. These results, tabulated according to uniform methods, will be sent to the National Department of Labor, according to the plans of the executive committee, and will there be consolidated into a complete report covering the entire United States. The features of this report will be furnished to the various State bureaus for use in their own reports, with such additional detail as they may think it desirable to furnish for local uses.

MR. W. F. BROWN, of Auburn, Me., has been made superintendent of the Bellows Falls Electric Light and Power system, which is owned by the Fall Mountain Paper Co., of Vermont.

THE ADAMOFF LUMINOUS FOUNTAIN.

An innovation in the operation of electric fountains has recently been introduced by M. A. Adamoff, a well-known manufacturer, of Baku, Russia. In this arrangement there is employed what is called an Adamoff prismatic wheel, consisting of two principal parts, namely, a hydraulic piston motor and a wheel, the whole supported on a cast-iron base. The piston of the motor communicates its motion to a wheel by means of a cam, in which there are successively engaged the steel pins, arranged regularly around the circumference on a solid disc, forming one piece with the wheel. The latter, of prismatic form, with a regular polygonal base, is mounted on a shaft turning on a horizontal bearing. It is arranged so as to receive the frames, in which are placed the colored glass plates, and these frames can be very readily replaced while the wheel is in motion. The wheel is installed in a compartment below the fountain.

The arc light employed is placed in front of a parabolic reflector, which throws the rays upon a plane mirror placed



Adamoff's Luminous Fountain.

within the wheel, which reflects them upward into the fountain, or the lamp can be arranged with a reflector directly within the wheel. By means of a cock and valve the wheel can be turned intermittently, and the periods of rest determined at will.

It will be readily seen that with a dozen or fifteen apparatuses regulated from one central point, the apparatus being all subjected to the pressure from the same water pipe, all the motors can be regulated to the same position, and thus a regular change of colors effected with the combinations determined in advance. It will also be noted that a great variety of combinations can be obtained by giving the motors different speeds.

C. B. ROUSS, the wealthy but blind Broadway "notions" merchant, wants to try the effect of a Tesla current on his optic nerves, and offers a fortune if any good results. Mr. Tesla is willing to administer the current, if the medical adviser approves, but declines the offered money.

THE ELECTRIC SCENIC COMPANY, of New York City, has been formed with a capital stock of $20,000. The directors are G. W. Bithridge, W. S. Munn, W. W. Thomas, T. P. Smith and Benton Murphin, all of New York.

HIGH VOLTAGE LAMPS AND THEIR INFLUENCE IN CENTRAL STATION PRACTICE.—II.

BY G. L. ADDENBROOKE, M. I. E. E.

Concurrently with this development there has been a tendency towards the use of lamps of ordinary voltage, but of higher efficiency, and I must say that until recently I have been unable to quite make up my mind which was the best of the two lines to work on—whether it would be better to use lamps of 100 voltage, and taking 2½ watts per candle-power, or lamps taking four watts per candle-power, with a voltage of 200 or 220. I think, however, the matter now admits of being argued out pretty clearly. By a reduction of current per candle-power, in the proportion of 2½ to 4, mains of a given capacity would do nearly double the amount of lighting with the same expenditure of energy. Energy in itself is very cheap, however, and any fair-sized central station could supply double the quantity of energy it is now doing at 1½d. per unit for the extra current, if this did not entail extra expense for extra mains. Now, by doubling the voltage, we reduce the size of the mains to one-fourth, other things being equal; consequently the mains for a station using 220-volt lamps consuming 64 to 70 watts per 16-c. p. lamp, to give the same percentage loss, would not be much more than half the size they would be if the station supplied 110-volt lamps consuming 2½ watts per candle-power, as the current would be nearly the same in both cases. As the cost of mains is such a very large proportion of the whole central-station cost, and, as energy can be generated so cheaply, I am fairly confident that, even if a good 2½-watt lamp were obtainable, it would pay better to use 220-volt lamps taking nearly double the current. Conversations with lampmakers, and recent publications on the subject have convinced me that a good 2½-watt lamp of 100 volts has yet to be attained, and will probably be a very difficult thing to achieve, unless absolutely even pressures in the mains can be guaranteed. The opinion of lampmakers appears universally to be that a 220-volt lamp at 3½ to 4 watts per candle-power is a more practicable and attainable object than a 100-volt lamp at 2½ watts. They seem also unanimous that if a good 2½-watt 100-volt lamp could be made, a good lamp of 220 volts, and of better efficiency than 4 watts, would be forthcoming. It therefore appears that by taking a 220-volt lamp now we shall get all the advantages of high voltage, and in time shall get nearly as efficient a lamp as if a lower voltage were used, while the high-efficiency lamp is even now in a far less forward state of development than the high-voltage lamp. Consequently, it seems clear that the high-voltage lamp is the better line of the two at present. Besides this, we are anxious to cheapen the cost of current so that it may also be available for power purposes, and thus small economies in consumption will be of less and less moment. It is, therefore, obvious that not only in the present, but for the future, the high-voltage lamp is likely to be the better, and that it is safe to run the risk of being unable to use very economical lamps, provided decent ones of high voltage can be obtained.

As I thought it would give a practical basis to this paper, and would be of interest to members to see specimens of some of the various high-voltage lamps which are being made, I have written to leading makers on the subject, and through their kindness am able to submit a number of 220-volt lamps, concerning which I will now give the particulars supplied by the makers.

Lamps to be arranged to burn; present data from makers, etc.: I shall not pursue this branch of my subject further, as it would be more suitably dealt with by a lamp manufacturer in a special paper; but I think enough has been said, coupled with the knowledge members already have of the subject, to show that high-voltage lamps are thoroughly practical for central-station work, and I therefore pass on to consider how far it is desirable to use them, and what effects they are likely to have on central-station practice—this being more immediately the subject of my paper.

Life of High-Voltage Lamps.—We can, of course, hardly expect the life of these high-voltage lamps to be as long as that of lamps of half the voltage, while at the same time they will be rather more expensive, consequently there will be a greater expenditure for lamp renewals when they are used; and it is advisable, I think, to try and arrive at a figure for this before proceeding further. If the life of an ordinary 16-c. p. lamp of 100 volts is 1,200 hours, and it consumes 64 watts, during its life it will consume 77 B. T. units, which, at 6d. per unit, amounts to 38s. 6d. If the cost of the lamp is 1s. 3d., its cost per unit of current consumed is 0.2d., or 1-5d., or about 3 per cent. of the cost of the current. For an eight-candle lamp of 100 volts, lasting 800 hours and taking 36 watts, the consumption of current is 29 units; and at the same price for lamps, the lamp cost per unit of current consumed is about 0.5d., or ½d., or about 8 per cent. of the cost of the current. I have assumed the above life for these lamps because I think, after burning the number of hours indicated above, most lamps would be best thrown away, though I am perfectly aware lamps often last twice as long as I have assumed, and they can also be purchased for 20 per cent. less from reliable makers. Two hundred-volt or 220-volt lamps will, of course, cost rather more, and their life would be rather less, but I believe I am putting the case more adversely for the higher-voltage lamps than is really true in taking the cost as double the above rates for lamp renewals where high-voltage lamps are used. The cost of lamp renewals would then be 6 per cent. of a customer's bill if the current was 6d. per unit for 16-c. p. lamps, and 16 per cent. if 8-c. p. lamps were used. Supposing the number of 16-c. p. lamps installed to 8-c. lamps is about as 1:2—which is, I think, about a fair average—an all-round reduction of 6 per cent. in the charge per unit of current would cover the additional cost of lamps, if lamps of high voltage were used; at 6d. per unit for current, this is about one-third of a penny per B. T. unit. Such figures as these can only be approximate, but I think you will agree that they would not be far out in practice, and may be improved upon, and also that they make it clearly manifest that the extra cost of using high-voltage lamps offers no appreciable bar to their introduction, providing that their other countervailing advantages are in excess, with which branch of the subject I will now deal.

Effect of Using High-voltage Lamps on Distribution.—On this point I do not think I can do better, as a commencement, than quote from my article in the "Electrical Review" of the 11th of January, 1895:—"How great a gain there is in distributing current at a higher voltage, and how much it simplifies the distributing problem, is not at first sight fully apparent, though everyone recognises that there are advantages. The advantages may really be said to progress as the cube of the voltage, up to, say, about 200 volts. For let us suppose we have a station on all of whose circuits the lamps require 200 volts to incandesce them, instead of the usual 100 volts. In the first place, having doubled the pressure, we may extend our mains double the distance at the same current-density, with the same percentage loss; but at the higher voltage the same current-density in a given sized main will give us twice the energy and light twice the number of lamps. Consequently, without increasing the sectional area of the mains, we can do four times the lighting with the same mains, or the same amount of lighting at four times the distance with the same percentage loss. Then there is a further gain, for, since we can extend the mains four times as far from the central station with the same percentage loss, the area which can be served from a single station is 16 times greater at the higher pressure than at the lower. Presuming, however, that this argument is not pushed to its extreme limits, it is well within the mark to say that at 200 volts nine or ten times the area could be better served on the three-wire system from a single station than is now the case at 100 volts; not only is this the case with the feeders, but it extends in an even greater degree to the distributing system. At present there is no doubt that there is an inconvenient fall of voltage in the distributing mains, and the internal wiring of houses, which leads to irregular and unsatisfactory lighting, and which is under existing circumstances, whatever system is employed, exceedingly difficult to remedy. If by any means the voltage could be increased to 200 volts this would practically vanish, distributing mains might be carried three times their present distance from the feeding point, and the fall of potential in houses would be merely nominal on the present basis of wiring, instead of frequently amounting to 1-2 volts or more. By these means the number of feeding points in a given area would of course be much reduced. The same fittings and wiring as are now used would be applicable, and the voltage does not go beyond the Board of Trade limits."

This was a general statement, made largely with a view to point out to manufacturers what a field it would open if they could produce a commercially satisfactory high-voltage lamp. During the last eighteen months manufacturers have seen the advantage of exploiting this field, with results which have already been detailed above. Consequently it is desirable to look a little more closely at the distribution problem under its new aspect, and I will, therefore, ask your particular attention to the figures which I now propose to lay before you.

THE ELECTRICAL TRADE WITH GERMANY.—Mr. H. Beneke, Flensburg, Germany, late U. S. Consul, informs us that he is now occupied in introducing American manufactures, especially of the electrical kind, into Germany, and that he will be glad to hear from any firms or persons desiring representation.

CONTENTS.

X-RAY THEORIES.

THE phenomena of the X-ray were well calculated to set the minds of thinkers at work to accommodate the observed facts to a comprehensive theory; but, though the facts are multiplying fast, it can hardly be said that they are yet sufficient to establish anything but hypotheses, and most of these even can only be of a tentative nature. Röntgen himself ascribed the X-ray to longitudinal ether vibrations, though by no means insisting on this view, owing to lack of complete evidence, and Jaumann has fortified this theory mathematically. Lord Kelvin has suggested the condensational wave theory as an explanation, while others have in turn attributed the X-ray to electrolytic and again to electrostatic sources. All these theories or hypotheses involve the ether, or an intermolecular action of some sort, but it remained for Mr. Edison to propose another explanation—the purely mechanical sound wave effect—to account for the observed phenomena. As was to be expected, this theory has not remained unchallenged, as our columns this week will bear witness. Nevertheless, Mr. Edison still maintains his opinion, and sees further confirmation of it in his more recent experiments. Briefly stated, Mr. Edison's theory is that the X-ray of Röntgen is a wave in air and matter, and not a wave in the ether—in other words, a sound wave; that it is not rhythmical, but a number of waves of various amplitudes and sequences. According to this theory these waves enter matter at the surface of the glass and are produced by the percussion of the molecules of gas and particles from the electrodes thrown with great velocity against the glass, and, by its elasticity, sent as a wave into space. The gas molecules, in turn, rebound from the glass with a diminished velocity or an energy minus that absorbed by the heating of the glass and the wave energy sent out into space. In the rebound they strike the glass chamber at another point, giving a second concussion and wave. Thus they probably vibrate back and forth a number of times. Hence the whole of the glass of the chamber gives out waves, but not so strongly as that portion which receives the primary concussion. Further, when the vacuum is too high, the ray is weakened by the number of molecules being insufficient to produce enough waves; on the other hand, when the vacuum is poor there is too much interference, or lessened free paths. There must thus be a critical point where there is the maximum number of molecules with the maximum free paths, and experiment proves this to be the case without any doubt. Mr. Edison is certain that there is a concussive action on the glass due to the cannon ball action of these molecules. The energy of these concussions is sufficient to even melt the glass, and if the X-ray is not due to the elastic action of the glass under concussion, then what, Mr. Edison inquires, becomes of these waves? These, at least, must be sound waves in matter and not in the ether. Their energy is great, their wave lengths are extremely short relative to ordinary sound waves, they should produce sharp shadows and they should perform work away from the tube. If they are not the X-ray, then there is another ray, a sound ray, and it only requires conditions to bring it out with great force. Mr. Edison contends that this concussion wave is the X-ray, and that the action on crystals of various substances causes the absorbed energy to be radiated as light.

We have given Mr. Edison's views somewhat in full here,

as explained to ourselves, so that they may be compared with other theories which have been proposed. Mr. Edison, as we stated last week, is well aware that many physicists will shake their heads at his explanation of the X-ray, but with his characteristic pertinacity he is maintaining it and seeking new facts to sustain it or to break it down.

ELECTRICAL EXPOSITION ACTIVITY.

THE rising tide of activity in matters connected with the National Electrical Exposition makes its mark in our pages this week, and the various items are but a superficial evidence of the work that is being done. It is already apparent that the exposition will be a success, but it was hardly expected that the public and daily press would soon quickly manifest an interest in it. Still that fact should not be surprising, for electricity is the great living center of movement and progress at the close of the nineteenth century, and the community is anxious and willing to learn all it can about its uses, old and new. As we have said before, the management cannot too strongly bring out the educational, novel, and entertaining features of the show, for the public will be drawn by them and the more commercial exhibits will thus in turn derive benefit and themselves attract by intrinsic merit. The National Electric Light Association bids fair to do the electrical science and art lasting good by this effort.

ELECTRIC VS. STEAM LOCOMOTIVES.

ELECTRIC railroading has reached that stage of development where it no longer requires argument as to its applicability to earn dividends on short lines heretofore operated by steam, and we may therefore expect to see more of the old roads equipped that way this spring. This short haul traffic is, however, more or less in the nature of street railway traffic, especially when we consider that some city roads operate lines 25 and 30 miles in length. What the railroad world is still on the lookout for is the solution of the long haul traffic problem by electricity. Steam railway engineers probably still regard the introduction of a general system of trunk lines operated electrically as far in the future, and they have been led to believe so as much by the statements of electrical engineers as by those of their own fraternity. By this we mean that electrical engineers of repute, in their conservatism, have in the past placed limits upon the electrical locomotive which seemed, for the present, at least, to bar it from general trunk line passenger service. It will be remembered that in answer to the question, "Will electricity take the place of steam for railroad purposes?" in his A. I. E. E. inaugural presidential address in 1892, Mr. Frank J. Sprague replied: "Only in part, and then only when the number of units operated between the terminal points is so large that the fuel economy would pay a reasonable interest and depreciation on the necessary cost of central station and the system of conductors." There is no doubt that, broadly, this statement of the case is correct, but thus far no one seems to have investigated to any practical extent the very point upon which the whole question pivots, namely, that of fuel, together with that of other, by no means insignificant items, such as repairs and running attendance. The articles by Mr. William Baxter, Jr., which we are now publishing, have shed a flood of light on this question, and represent probably the first exhaustive treatment of this important question. Mr. Baxter, by analyzing the reports of present steam trunk lines, has developed several striking points, tending to show that electricity is far closer to the point of practical economy under existing traffic conditions than had been suspected, and in this issue he still further strengthens his argument by showing the favorable status of the electric freight locomotive as compared with the steam locomotive. We will not anticipate Mr. Baxter's final conclusions as applied to an actual case, but what has already been shown will be sufficient, we think, to lead railroad men to look seriously to the electrical possibilities with which they may have to deal in the not distant future.

PISTOLS OR ARC LIGHTS?

AT the recent meeting of a Commercial Club in the West, an argument was made in favor of street lighting by electricity that is one of the most convincing we ever saw. It is not new to consider an arc light as equal in efficiency to one policeman, or even equal to two, but we have never observed the matter stated quite so strongly before. One of the members produced an old pistol, flourished it in the eyes of his startled fellows, and then said:

"As I sat reading my evening paper a young woman dashed into our house, breathless and disturbed. When she had caught her breath, she told me that she had been pursued by a negro. I know her to be a truthful person, and I know that on a former occasion in the city where she worked nights she held a highwayman at bay with a pistol, and it seems the villain still pursues her. I got out this pistol, escorted her home, and came up here to suggest that we all keep a lookout for the ruffian who frightened her."

It is needless to add that the club proceeded to vote forthwith in favor of electric lighting. Only one vote was recorded in favor of pistols as a protection to chastity, and that came, it is said, from a "high-toned gentleman," who preferred the older regime of affairs, when life in his section of the country was one long Schuetzenfest.

COMPENSATION OF ELECTRICAL ENGINEERS.

WE are glad to learn that a long since suggested movement has been started in Chicago, the object of which is to establish or maintain a uniform schedule of fees for electrical engineering work and the enforcement of a stringent code of professional ethics. It is proposed that a society shall be organized for this purpose, answering to the societies of architects. It would have seemed at first blush that the American Institute of Electrical Engineers is the best body in the country to take a hand in sustaining professional dignity and honor, but as that society was reluctant even to lend its consultative aid to the establishment of a code of national rules for proper electrical construction, it is obvious that the organization suggested at Chicago has a clear and specific field. It is urged that the fee for independent consulting electrical engineers shall not be less than 5 per cent. for entire charge and supervision of plants, and that they shall do no construction work nor be connected with selling agencies. The movement, on its broad lines, has our heartiest approval, and we trust it will succeed. The electrical engineer cannot too soon be put on the same level as his professional brother—the architect—for he belongs there by virtue of his training, experience and responsibility; and an inflexible professional code applies to his vocation as much as to any other branch in the domain of engineering.

TELEPHONY AND TELEGRAPHY.

ON TELEPHONIC DISTURBANCES CAUSED BY HIGH-VOLTAGE CURRENTS.[1]—I.

BY DR. V. WIETLISBACH,

AFTER a brief summary of the conflict of interests between telephone and power undertakings the author proceeds as follows:—

The injurious disturbances to telephone lines, in so far as they are traceable to the action of the electric current, may be considered under three heads:—

I. The high-voltage current may enter the low-voltage line in consequence of accidental contact with a telephone wire, or in consequence of other accidents, such as the fracture of a pole, support or wire. If the tension of the intrusive current be high, the intensity of the current may become so great as to destroy the telephone apparatus or melt the telephone conductor; or again, the latter may become so overheated as to ignite any wooden parts near it, and thereby set even large telephone stations on fire, such occurrences having already occasioned damage amounting to millions of francs.

II. When the high- or the low-voltage line is either uninsulated, or insufficiently insulated from earth, or when both lines are carried on the same poles or supports, part of the high-tension current may enter the telephone line through earth not only occasionally, i. e., under exceptional circumstances, but permanently. If the high-voltage current be a perfectly constant direct current, such as, e. g., that supplied from a storage battery, no effect is noticeable in the telephone except that the sensitiveness of the apparatus is somewhat impaired when the tension of the high-voltage current exceeds a certain limit. But if the high-voltage current be pulsating, which it always is where continuous current is used for driving car motors; or, again, if the high-voltage current be a single or polyphase alternating current, a humming noise is set up in the telephone apparatus, the humming being less violent in the case of a pulsating direct current, but very violent in the case of an alternating current, so that in either case telephonic communication may be rendered difficult or altogether impossible.

III. The high-voltage current affects low-voltage lines in the neighborhood by induction, i. e., to every rise and fall of the high-voltage current there is a corresponding electric wave in the telephone line, the intensity of that wave being proportional to the oscillation in the high-voltage line current; in other terms, a succession of electric waves in one conductor is faithfully reproduced by a similar succession of waves in the other. There is an essential difference in the effect of electro-magnetic and electrostatic induction. In both cases the electromotive force is proportional to the magnitude of the change in the primary, i. e., the inducing current, and is governed by the reciprocal position of the lines and by the distance over which the two lines run parallel to each other.[2] In the case of electromagnetic induction, the intensity of the induced current set up is inversely proportional to the resistance, i. e., it decreases as the length increases. On the other hand, in the case of electrostatic induction, the intensity of that current is proportional to the capacity of the affected line, and, therefore, also proportional to the length of the latter. Hence electromagnetic induction predominates, generally speaking, in short lines, and electrostatic induction in long lines, independently of the distance over which the two sets of conductors run parallel to each other.

The disturbances considered under I. may be counteracted by lead fuses inserted in the telephone line at the point where the latter enters the building, and which melt when the intrusive high-voltage current exceeds one ampere. By that means the line is interrupted, and damage to the telephone apparatus is rendered impossible. There is no difficulty in constructing safety fuses, which are far more sensitive than those mentioned; but they offer no practical advantage, because they melt much too easily even in the case of very light thunderstorms, and hence only produce innumerable interruptions which greatly interfere with the regular working of the telephone service.

When the tension in the high-voltage line exceeds 500 volts, the arc which forms at the safety fuse is not immediately extinguished, and may, therefore, become even more dangerous than the high-tension current itself. In such cases special devices are necessary in order to prevent the formation of an arc or to insure its immediate extinction when formed. To this end, the wire fuse is enclosed in long glass tubes or imbedded in sand, and no combustible materials must be kept in the immediate neighborhood.. With a view to prevent the bursting of the glass tubes or render the bursting harmless, they are encased in fibrous material. When an intrusive current of sufficient amount arrives at the wire-fuse, the latter is explosively vaporized and the vapor is expelled from the glass tube. The explosion at the same time extinguishes the arc if such be formed. There are various other means of counteracting the overheating of telephone wires and apparatus; but the higher the tension the more complicated and inconvenient are the safety contrivances.

The disturbances considered under II., i. e., the humming produced in telephone apparatus by intrusive undulating or alternating currents, may be avoided by insulating the telephone line as carefully as possible from earth, as well as from any parts which may be connected with the high-voltage line. But when the tension in the latter exceeds 500 volts, that precaution is not always sufficient, the less so because, in practice, it is impossible to maintain either high or low-voltage lines at all points and permanently in a state of perfect insulation. The practical application of both classes of currents frequently involves the necessity of installing the conductors in damp, or otherwise unfavorably situated places, business premises, etc.; and having regard to the high tension of the one class of installation and the extreme sensitiveness of the apparatus of the other, an almost infinitesimal leakage, amounting to only one millionth of the total current, suffices to produce a very marked telephonic disturbance. It is on this account that the juxtaposition of the two can be rendered bearable only by carefully insulating both systems from earth. It is, moreover, but fair to require that the conditions which are imposed upon one class of installation should also be made obligatory upon the other, if it be for the general and public advantage.

[1] From the London "Electrician." Translated by Dr. C. S. du Riche Preller. This paper is a Report just published at Berne (*Blätter für Electrotechnik*), and was kindly communicated by Dr. Wietlisbach to the translator. The translator is of opinion that it strikingly confirms the facts and conclusions recently set forth by him in *The Electrician* (January 10, 1896, "Electric Tramways and Telephonic Disturbances"). The author uses the term "high-voltage currents" (500 volts and above) as contrasted with low-voltage telephone currents.

[2] [The phraseology of what follows is not so clear as could be wished, but it is a faithful rendering of the original.—ED. *E.*]

INTERNATIONAL CHESS BY CABLE.

The Commercial Cable Company has issued a neat little folder giving the details of the recent international chess tournament conducted over its cables. The messages went from Brooklyn to New York, thence through the Narrows and past Coney Island to Cape Canso, Nova Scotia, 850 miles; thence to Waterville, Ireland, 2,161 miles; thence around the south coast of Ireland to Weston-super-Mare, in the Bristol Channel, 329 miles, and thence to London, 143 miles more. The total distance traveled by each message was 3,483 miles, yet the arrangements were so perfect that each player knew what his opponent had done in fifteen seconds after each move was made. Each move was noted on a slip of paper, which was handed to the operator.

BERMUDA CABLE EXTENSION SCHEMES.

Mr. D. Budge, superintendent of the Halifax and Bermuda Cable Company, has gone to Ottawa to ask the government for a subsidy to enable his company to extend its present cable from Bermuda to Jamaica. He says that the West India merchants of Nova Scotia and New Brunswick are unanimous as to the necessity of cheaper rates and a more direct cable service for the development of trade. The present rate from Halifax, N. S., to Jamaica is $1.19 per word. This rate the Bermuda company proposes to reduce to 50 cents per word, if assistance be given by the Dominion and Imperial governments. This, it is claimed, would lead to the opening out of new commercial routes for trade. The project has been favorably received in England.

SECRECY AS TO CABLE TERMINALS.

It has been decided by the Bermuda Cable Company to keep secret the position of their cable from Halifax to Bermuda. The cable goes out the western side of George's Island, Halifax, N. S., but after that its course is not known outside of the office of the company. Its course after leaving the coast is also kept a secret, and is not marked on any of the public charts in use. The cable is considered to be of great strategic importance and its location is desired to be kept secret to prevent any possible attempt in time of war to cut this line of communication between Halifax and Bermuda.

THE UNITED STATES CONDUIT COMPANY has been formed with a capital stock of $25,000 by Jacob E. Ridgeway, W. Miller and S. S. Miller, all of Philadelphia.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—VIII.

Wm. Baxter, Jr.

THERE are no available data from which the average number or weight of cars in a passenger train can be obtained, but it is very evident that five cars would be a very liberal allowance, and 65,000 pounds for each would more than cover the average weight. Estimating on this basis we would have:

Five passenger cars	162.50	tons.
Locomotive of average weight for passenger service	85	tons.
Average number of passengers, 106 (see Table 8) @ 120 pounds each............	6.36	tons.
Total weight of train..............	253.86	tons.

Weight of locomotive equals 33.4 per cent. of total weight of train. Weight of electric motors required to replace the locomotive and do the same work, 22 tons.

Total weight of trains drawn by electric motors:

Cars	162.50	tons.
Passengers	6.36	tons.
Motors	22.00	tons.
Total	190.86	tons.

Weight of motors equals 11.5 per cent. of total weight of train. Weight of train drawn by electric motors equals about 74.4 per cent. of same train drawn by locomotive. Saving in power required to do the same amount of work in passenger service, about 25.6 per cent.

The saving in power required to move trains of the same weight is, according to the foregoing, nearly 8 per cent. for freight, and over 25 per cent. for passenger service. While the saving in energy in moving freight trains is small, comparatively, the saving in coal would be great, owing to the fact that the efficiency of freight locomotives is much lower than that of engines used in high speed passenger work. If the efficiency of electric motors were dependent upon the speed, as is the case with locomotives, then for freight service the saving that could be effected by the former would not be as great as in passenger traffic; but, taking the facts as they really are, it will be found that in one line of work the gain is about as much as in the other.

In the opening paragraphs of these articles it was shown that the average coal consumption of large engines could be safely taken at two pounds per hour, and the efficiency of transmission was assumed to be 60 per cent., from which we can deduce that the consumption per horse-power delivered on the track would be 3.33 pounds per horse-power hour. In other calculations based on the actual work of freight locomotives on a large number of roads, we have shown that the average result is about 10 pounds per hour. But, in order to not be accused of partiality, we will here assume that freight engines can develop a horse-power at the rate of 6 pounds per hour. The performance of passenger locomotives may be taken as low as 4 pounds. As the difference in cost of coal—owing to the fact that the stationary engines in the power station of an electric system would use a cheap grade—would be about 33.3 per cent., the actual cost of energy delivered on the track would be as follows:

$$\left.\begin{array}{l}\text{Passenger engines}\ldots\ldots 4\ (\text{lbs}) \times 100\ (\%) = 400. \\ \text{Passenger motors}\ldots 3.33\ (\text{lbs}) \times 66.6\ (\%) = 208.\end{array}\right\}\ 50\ \%\ \text{app.}$$

$$\left.\begin{array}{l}\text{Freight engines}\ldots\ldots 6\ (\text{lbs}) \times 100\ (\%) = 600. \\ \text{Freight motors}\ldots 3.33\ (\text{lbs}) \times 100\ (\%) = 208.\end{array}\right\}\ 33.3\ \%\ \text{app.}$$

From these figures we see that the horse-power delivered on the track costs three times as much by steam as by electricity for freight work, and twice as much for passenger service. Now, multiplying these figures by the relative percentages of the power required in both cases to haul given loads, we have:

$$\text{Freight}\ldots\ldots\frac{92.2 \times 33.3}{100 \times 100} = 30.7\ \%.$$

$$\text{Passenger}\ldots\frac{74.6 \times 50}{100 \times 100} = 37.3\ \%.$$

That is to say: The cost of coal consumed to move a given load by electricity is about 31 per cent. for freight and 37 per cent. for passenger work of what it costs by steam.

From these figures we see that the saving in coal is even greater in freight work than in passenger, a result that will surprise many, as it has always been conceded by the friends of electricity that it could only expect to compete with steam in high speed work.

Although these results show that the saving in coal would be greater in freight service than in ordinary passenger work, it must be remembered than in obtaining the ratio between weight of locomotive and passenger train the number of cars was assumed to be five, which is undoubtedly more than the average, but this was done so that it could not be said that the estimate was unfavorable to steam. It is more than probable that if we could obtain the actual relation between weight of cars and engine, we would find that the percentage of coal saving would be about the same for freight as for passenger service. It must not be inferred from this, however, that this relation would hold good at all speeds. When very high velocities are considered, it will be found that the superiority of electricity over steam increases very rapidly, owing to the fact, as already shown, that there is a limit to the power that a locomotive can develop, while, practically, there is no limit to the output of an electric motor. As a proof of the truth of this statement I will here reproduce a table showing the result of tests made by Mr. Angus Sinclair, of the locomotive drawing the Empire State Express on the New York Central railroad:

TABLE 10.

PARTICULARS OF TESTS OF EMPIRE STATE EXPRESS LOCOMOTIVE.

FROM INDICATOR DIAGRAMS.

No. of Diagr'm.	Throttle opening.	Reverse lever notch.	Point of cut-off.	Boiler pressure.	Rev. per minute.	Speed in miles per hour.	Indicated horse power.
1	¼	18	8½	160	160	37.1	648.3
2	¼	18	8½	165	280	60.8	728
3	⅛	18	8½	170	190	44	551
4	⅛	18	8½	170	250	58	871
5	¼	18	8½	160	260	60	960
6	⅜	19	7¼	160	298	69	983
7	⅜	19	7¼	160	304	70.5	977
8	⅜	19	7¼	165	296	68.6	972
9	⅜	19	7¼	165	300	69.6	1,045
0	½	19	7¼	170	304	70.5	1,059
11	½	19	7¼	165	340	78.9	1,120
12	½	19	7¼	165	310	71.9	1,026

An inspection of the last column in this table will show that for the last four observations the power is nearly constant. The fact that the power required at 71.9 miles is less than at 69.6 would indicate that in the latter case the train was going up a slight grade, or else was descending in the former.

It does not seem necessary to give a demonstration here of the truth of the statement that the output of a locomotive is limited, as the fact is so self-evident that it must be conceded without argument. The question, however, to be decided is, what is this limit? If we were to draw our conclusions from this table we would say, about 1,100 horse-power; but in order to be on the safe side we will assume it to be 1,250 horse-power. Taking this figure as the limiting capacity of a locomotive, we can readily show the relation between steam and electricity at high speeds, and, as the matter of more rapid transit between cities is receiving considerable attention at the present time, this is a point worthy of investigation.

PLATTSBURG, N. Y.—The Plattsburg Traction Company has secured a franchise for a six-mile electric road to run from Hotel Champlain to the Normal School, and fair grounds, with a branch to the depot and dock. The project is very popular in Plattsburg, and the company is only waiting for the frost to be out of the ground to begin the construction of the line. The incorporators of the company are: H. M. Pierson, president; H. E. Barnard, treasurer; A. E. Reynolds, secretary; George M. Cole, manager Incandescent and Arc Light, Electric Power and Gas Works; S. M. Weed, H. G. Runkle, D. F. Dobie, T. F. Conway, W. H. Chappel, J. O. Smith, Geo. S. Weed, M. B. Snevily, S. D. Curtis, J. H. Bagg, John B. Riley, W. L. Pattisson, and T. F. Mannix. The power house of the company is of brick and stone. The generating plant consists of Westinghouse incandescent and Westinghouse arc machines, including three 800-light alternators, one sixty 2,000-candle-power arc, and one 500-volt 100-horse-power generator. The converters are Westinghouse, with 225 Shallenberger meters. There are 15 motors on the circuits. In the engine room are two 100-horse-power Ball en-

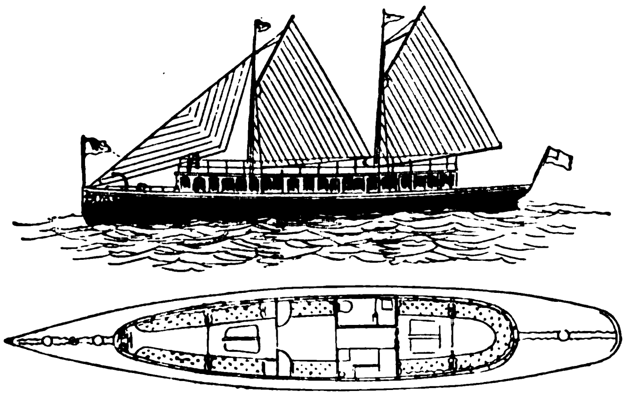
gines, with two 130 horse-power boilers, and three 100-horse-power Hercules water wheels. As a matter of fact, the present plant is that of the Plattsburg Light, Heat and Power Company, the two companies being practically identical.

MR. JOHN JACOB ASTOR'S NEW ELECTRIC YACHT.

MR. JOHN JACOB ASTOR is well known to be an enthusiastic electrician. The building of electric launches in the United States has long lagged far behind the active work of the English builders, and to Mr. Astor's enterprise is owing not a little of the stimulus which has of late been given to the development of this industry on this side of the water.

Mr. Astor's first electric yacht, the "Corsira," was run by a small storage battery. It was last year improved on by the "Progresso," a forty-foot boat. Mr. Astor has now given an order to a Nyack firm for the construction of the largest, finest and most completely equipped electric auxiliary yacht in the world. The boat, which has not yet been named, will be seventy-two feet over all, twelve feet beam, and four feet draught. She will be fitted with twin screws, which will be run by two electric motors capable of developing fifty horse-power. The maximum speed is to be sixteen miles an hour, at 1,000 motor revolutions per minute. Her ordinary speed will be about ten or twelve miles an hour, and her batteries of 480 cells will run ten hours without recharging.

The cells, as well as the motors will be placed entirely below the deck, and will not in any way interfere with the cabin space. The entire boat, decks, planking, and interior finish, will be of polished mahogany, except the quartered oak gun-



MR. J. J. ASTOR'S NEW ELECTRIC YACHT.

wales. The hull will be of peculiar form, having a channel-way for each of the propellers, and there will be two Tobin bronze centerboards, worked by electric capstans from the promenade deck. The boat will be fitted with electric capstans, and a large chamber connected with air pumps will supply air for blowing the whistles, which will consist of a set of chimes. Electricity will also drive the pumps for freeing the boat from water in case of leakage.

In addition to her battery equipment, the new yacht will be rigged as a schooner, and will have ample sail plan in case her machinery is disabled. The yacht is being constructed by Charles D. Mosher, the designer of the fast yachts, "Norwood," "Feiseen," and "Yankee Doodle," and is to be finished by June 1.

MARRIED.

MR. C. I. HILLS.

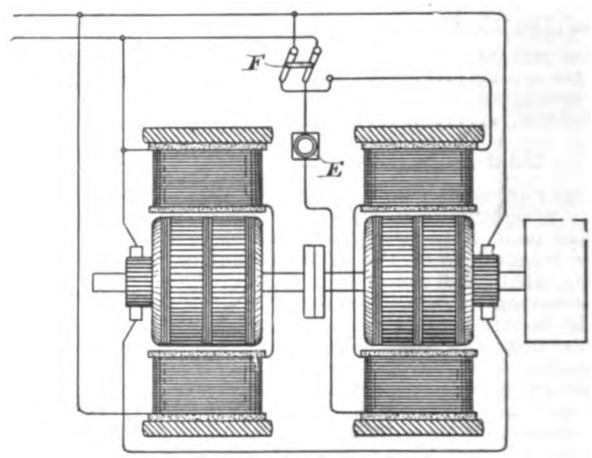
Invitations have been sent out for the marriage of Mr. Charles I. Hills, and Miss Matilda King, of Elizabeth, N. J., which will be celebrated in Westminster Church, Elizabeth, on Wednesday afternoon, April 24, at 4 o'clock. Mr. Hills is well known to every one in the electrical business, having for years been connected with the old Perkins Electric Lamp Company. For a time during the lamp troubles, Mr. Hills was associated with the Columbia Incandescent Lamp Company, of St. Louis, but when the Perkins Electric Switch Company, of Hartford, began the manufacture of incandescent lamps, he severed that connection and became New York agent for the latter company. Since that time he has been appointed general manager for the sales department with offices in the Havemeyer Building, New York, and has established a large business. There is no better known nor better liked man in the electrical trade than Mr. Hills, and his hosts of friends are offering him congratulations on his approaching marriage.

POWER TRANSMISSION.

BURKE'S METHOD OF REGULATING MOTORS.

IN the operation of electric motors from supply circuits, conditions are sometimes encountered in which a wide variation of speed is desired or essential. An example of this is a condition in which, for instance, it is required to deliver 10 horse-power at any speed between the limits of 100 and 500 revolutions, and to maintain this delivery at any desired speed between the limits above referred to.

To accomplish this result, there have been two methods in use, one of which is to vary the speed by interposing resistance in the armature circuit, thereby reducing the voltage on the armature and consequently the speed. This method has the disadvantage that there is a comparatively large loss in the resistance, and consequently a low efficiency. The other method is to reduce the voltage upon the armature of the motor by introducing a rotary transformer between the supply circuit and the motor to be operated, which transformer is so arranged that the voltage supplied to the motor may be varied between the limits of zero and a predetermined maximum. This method has the disadvantage of a large investment in dynamo machines, because the rotary transformer used consists of a primary motor and a secondary generator, each of



BURKE SYSTEM OF MOTOR REGULATION.

which has an output equal to that of the main motor to be operated.

In the method about to be described, instead of using one motor, two machines are used, each of which will give one half the desired delivery. For instance in the condition previously referred to, two motors of five horse-power each at 100 revolutions are operated in unison, and co-operate with each other so as to fulfill the requirements of 10 horse-power delivery at any speed between the desired limits.

The accompanying illustration shows a diagrammatic embodiment of the method. The machines are coupled directly, E representing a rheostat, and F a reversing switch.

The action in general is as follows: In starting and when operating at minimum speed, the two machines are acting in unison as motors. The speed is gradually increased until it reaches its predetermined maximum, first by reducing the field of one of the machines, thereby transferring the voltage of the line to the other, and then by reversing the field on the former machine and gradually increasing it, thereby adding to the line voltage the voltage of the former machine, the latter machine receiving the combined voltage. This method is due to Mr. James Burke, of New York.

ELECTRICAL EVENTS AT NIAGARA FALLS.

The announcement is made that the Niagara Central Railroad, which is about 12 miles long and runs between Niagara Falls, Ont., and St. Catharines, Ont., will this spring adopt electricity as a motive power. It is stated also that as a steam road, the Niagara Central has not been over-profitable, and it is expected that electricity will bring about a radical change in this respect. The road runs through a good country, and there is no reason why electricity should not prove a beneficial change.

It now looks as though the Niagara Falls Hydraulic Power and Manufacturing Company would receive a franchise from the Legislature of this State, the Assembly having passed the

bill confirming and defining certain riparian rights of the company. There is no opposition to the bill, the commissioners of the State reservation having approved its provision that the company be allowed to develop 100,000 horse-power, which is the same amount as the capacity of the tunnel of the Niagara Falls Power Company.

One day recently a number of Cornell College students paid a visit to the plant of the Niagara Falls Power Company at Niagara Falls. While there they made a 500-volt short circuit. The result was that the fuses were blown out with a startling explosion, while the wattmeter they brought with them was demoralized. Naturally, the students were somewhat frightened.

THE SODA AND POTASH WORKS AT NIAGARA.

THE Walton Ferguson Chemical Company's plant at Niagara Falls will be started in April or May. This plant is the latest one built on the land of the Niagara Falls Power Company. At present it consists of two buildings, one of which is 60 x 125 feet, and the other 30 x 60 feet. Both are two stories high and built of wood. This company will manufacture potash and soda electrically on a large scale, and no doubt their influence will be felt on the market.

All the electrical appliances, transformers, etc., will be located in the smaller building, while on the upper floor of the larger buildings will be placed the large porcelain-lined iron tanks designed to contain the crude material for the manufacture of potash and soda. These tanks will be about 100 in number, and they will form one of the features of the electrical industrial development at Niagara Falls. In size they are expected to be about the largest vessels ever made with complete and unbroken porcelain lining. A large portion of the lower floor will be devoted to office room and the boxing and shipping departments.

When the plant begins its work it will consume about 1,000 horse-power, but it is intended to enlarge the factory until it shall be about eight times its present size, and then its capacity will be likewise increased. It is probable that all future buildings erected by this company will be built of brick. In the case of the two buildings just erected they were deterred from using either brick, stone or iron, fearing the action of the gases generated would prove detrimental, but now they are confident brick will be a safe material to use, and they will adopt it.

One ton a day will be the capacity of the present plant, and the rock salt for making soda will be obtained in Syracuse. From Germany will come the crude material for making potash. The product of the company at first will be put up in packages of 100 lbs., but later on they will adopt a canning process controlled by them. In this process machinery will be used, and the cans packed in cases by hand ready for shipment. As yet the subway in which the cables carrying power to the aluminum and carborundum works have not been extended so far as the carbide or soda plants, but they soon will be, and until they are, the power will be conducted by cables carried above ground.

A MULTIPHASED SHOE SHOP.

The operation of shoe factories by electricity seems to be making steady headway. A few weeks ago we noted the equipment of the large Drew-Selby plant in Ohio, with electric motors throughout by the General Electric Company. The same company is about to undertake the electrical equipment of the Norway Shoe Shop Company, of Norway, Me. Seven non-synchronous multiphase motors, aggregating 100 horse-power, will be put in. The current will be taken from the 250-kilowatt, three-phase generator recently set up in its station by the Norway Electric Light Company.

COLUMBIA, S. C.—The following contracts have been awarded for the power plant for the Columbia Water Power Company, to cost over $200,000 (A. G. Stevens, engineer, Manchester, N. H.): W. A. Chapman & Co., Providence, R. I., power house, forebay races and wheel pits, setting wheels and electric generators; General Electric Company, Boston, Mass., eight electric generators; Rodney Hunt Machine Company, Orange, Mass., eight pairs McCormick waterwheels of 1,300 horse power per pair; total, 10,500 horse power; 29 feet fall.

THE UNITED VERDE CO., Arizona, are putting in an electric power plant to be used for all the underground work in their mine, supplanting all steam power.

HIRAM S. MAXIM is going to write a series of articles on automatic firing guns for "Industries and Iron".

EDUCATIONAL.

COLUMBIA UNIVERSITY'S NEW ENGINEERING BUILDING.

THE Engineering Building, which is soon to be erected on the Columbia University grounds at Morningside Heights, will contain the departments of civil, mining, mechanical, and electrical engineering. It will be 150 feet long, by 55 feet, and will have 52,000 square feet of floor space. The greatest care has been exercised in the general design of its construction, and

THE NEW ENGINEERING BUILDING, COLUMBIA UNIVERSITY, NEW YORK.

in one respect especially, that of ventilation, its arrangements show admirable judgment. An idea of the amount of air that will be forced through the building can be obtained from the fact that two twenty-five horse-power electric motors will be required to operate the supply fans, and three ten horse-power motors to operate the exhaust fans. The large lecture room in the center of the building will seat 450 students. It will be lighted from the dome as well as from the sides, and its extreme height will be 40 feet. On the third floor, the east wing will contain the qualitative and the west wing the quantitative laboratory. Each laboratory will have 4,000 feet of floor space. The body of the building will contain a chemical laboratory and reading room, a laboratory for electrolysis, and gas analysis, and another for water and volumetric analysis, and a photometric room.

THE NEW CASE SCHOOL ELECTRICAL LABORATORY, CLEVELAND.

THE growth of the electrical engineering department of the Case School of Applied Science, Cleveland, and the rapid accumulation of apparatus and laboratory appliances caused by the progressive policy of the management, have

THE NEW ELECTRICAL LABORATORY,
CASE SCHOOL OF APPLIED SCIENCE, CLEVELAND, OHIO.

made a new building for the department a necessity. The building was begun early in the summer of 1895, and is now completed. It is situated near the mechanical engineering

laboratory. The power for driving the dynamos is furnished by the Corliss engine in the shop, and steam for heating is taken from the boilers in the machine ship boiler room. The shafting and the return pipes are all carried in a covered conduit running from the mechanical to the electrical building.

The building is 104 feet long and 64 feet wide. The basement is occupied by a large dynamo room, 60 feet square, and three smaller laboratories. On the first floor are the lecture room, testing rooms, and an office for the professor of the electrical department. On the second floor is an assembly room 60 feet square, with rows of seats rising gradually to the rear of the room. This room will hold nearly 600 people, and is said to be one of the finest lecture halls in the city. The top floor has a drawing room 60 feet square, lighted by a skylight, and some smaller class rooms. The building will be lighted throughout by electricity, and heated by steam. It will be ready for occupancy next fall, and will be a most valuable addition to the resources of the electrical department of the school.

CORNELL UNIVERSITY REGISTER FOR 1895-6.

The Register for 1895-96, of Cornell University, shows conclusively that Ezra Cornell's intention to "found an institution where any person can find instruction in any study," has been carefully borne in mind in the maintenance of the curriculum of the splendid university which he founded. As Dr. R. H. Thurston, in a recent paper on the needs and opportunities of a great technical college, says:

"Among the great opportunities of the world, in the promotion of the best interests of the people, are those to-day to be found at Cornell University and largely in connection with the organization of Sibley College. Original research is now universally recognized as the 'essential preliminary to the fullest development of industry,' and the thousands of schools of France and Germany and all their technical colleges and their universities, whether technical or other, are organized in recognition of this fact. The hundred weaving and designing schools of England, her technical colleges, and her trade schools are taking a similar constitution, and in Manchester alone 14,000 students are nightly profiting by the systematic manner in which that nation has entered upon the task here set before Cornell University by our own nation and State. Yet nowhere can be found a better substructure and larger opportunities for the erection of an orderly and systematically planned and mutually helpful aggregation of colleges and schools than in the United States and at Cornell University to-day."

It is gratifying to see that the standard of electrical training, which has for a long time been a special feature of Cornell, is being adjusted to meet the requirements of the rapidly widening electrical field.

PERSONAL.

MR. J. H. VAIL.

It will be a source of pleasure to a wide circle of friends and acquaintances to learn that Mr. J. H. Vail, dating from April 1, has been appointed engineer-in-chief of the Pennsylvania Heat, Light and Power Company, of Philadelphia, and also of the Edison Electric Light Company, of Philadelphia. He will also have engineering charge of all the sub-companies that have recently been consolidated in the Quaker City. The system thus entrusted to Mr. Vail's care, experience and fidelity is simply enormous, but they who know the man are satisfied that he will discharge his responsibilities to the full. It will be readily understood that the new developments will require a considerable readjustment of plans and plants, but Mr. Vail's work peculiarly qualifies him for success in that difficult field.

MR. J. ELLIOT SMITH, the Superintendent of Fire Telegraphs of New York City, has been suspended from duty, pending further investigation of serious charges against him, on the score of favoritism and paying high prices for supplies. His friends claim that commercial animus is back of the charges, and that he will be vindicated.

MR. R. E. WRIGHT of Allentown, Pa., has been re-elected president of the State Electric Light Association of Pennsylvania.

DINNER TO MR. E. M. SCRIBNER.

A dinner was given by Mr. Chandler of the American Circular Loom Company, Chicago, to Mr. E. M. Scribner who is leaving the Western Electric Company, to take the place of business and sales manager for the Bryant Electric Company, of Bridgeport, Conn.

The affair took place at the Great Northern Hotel April 2, and was attended by Messrs. Crandell, Wilkinson, and Scribner, of the Western Electric Company; Mr. Wolff, of the N. Y. Insulated Wire Company; Mr. Morse, of the Kerite Company; Mr. Chas. E. Brown, of the Central Electric Company; Prof. John P. Barrett, and Messrs. Brooks and Chandler, of the American Circular Loom Company.

MR. W. D. SARGENT, manager of the New York and New Jersey Telephone Company, has recovered rapidly from his recent surgical operation. He has the nine lives of a cat, and will probably be quoted in the middle of the next century as a striking instance of the longevity of electricians.

OBITUARY.

W. H. WHITACRE.

William H. Whitacre, a leading citizen of Alliance, O., for many years passenger conductor on the Cleveland and Pittsburg Railroad, died on April 2, aged 57. Several years ago he built the Alliance Electric Railway and was general manager of the company at the time of his death.

WM. S. BEATTY.

The many friends of Mr. Wm. S. Beatty, of the Pittsburg office of the General Electric Company, will be pained to learn of his death, April 7, in New Orleans. Mr. Beatty was obliged to give up his work some weeks before, on account of failing health, and to seek a more congenial climate in Florida, and later in Arizona. Finding no improvement, however, he was on his way home, but on reaching New Orleans was unable to proceed further. Mr. Beatty was a comparatively young man for the position he filled, and had marked abilities which gave great promise for a brilliant future. His agreeable and obliging manners made him friends everywhere, and his sudden death comes as a great shock to them all.

JUSTIN J. GATES.

Our readers will be sorry to learn of the death of Mr. Justin J. Gates, who died at his home a few days ago from an attack of typhoid fever. Mr. Gates was particularly well known in the incandescent lamp business, having been associated with manufacturers of incandescent lamps for many years. His first association with an electric company was when he entered the employment of the Mather Electric Company as bookkeeper, shortly afterwards resigning to become the secretary and general manager of the Perkins Electric Lamp Company, a company which Mr. Gates was himself prominent in organizing.

Mr. Gates was well known in connection with this company until it was forced to suspend operations owing to the incandescent lamp litigation, after which he associated himself with the Waring Electric Lamp Company, of Manchester, who manufactured the Novak lamp, and which company was also forced to suspend operations by litigation before many months. Some time later Mr. Gates was appointed to the position of general manager of the Perkins Electric Switch & Manufacturing Company, of Hartford, when they commenced manufacturing incandescent lamps. This position he held until quite recently, when he retired, and at the time of his death was busily engaged in the lamp business for himself.

Mr. Gates was always prominently known to purchasers of incandescent lamps, and his uniform courtesy and business integrity won for him hosts of friends, who will all join with us in regrets that he should have been carried away at this time while just in the prime of life.

WARREN ELECTRIC AND SPECIALTY CO.

The above company, of Warren, O., forward us their catalogue of incandescent lamp specialties. It is their first publication on the subject, and gives evidence of energy and enterprise. In the manufacture of their filaments, they use both bamboo and cellulose, and they make any efficiency from 3 up to 4½ watts per candle. Their catalogue shows a range of 10 and 16 candle-power lamps, but they make also 4, 6, 8, 32, 50 and 100 candle power, and have ready also a line of colored lamps. All of their product is supplied with base as ordered. The manufacture of their lamps is under the expert guidance of Mr. F. E. Cavanaugh. The officers of the company are T. H. Gillmer, C. H. Angstadt and E. W. Gillmer. The headquarters are at 670 West Market street, Warren, O.

Exhibition Notes.

WHAT EXHIBITORS WILL DO.

LAST week we printed a number of notes as to what exhibitors at the National Electrical Exposition propose doing. This week we are able to furnish further interesting details.

The Crouse-Tremaine Carbon Company, of Findlay, O., will exhibit samples of their solid and cored carbons for arc lighting purposes. They will also have a nice display of their motor and generator carbon brushes, and other specialties.

The Holtzer-Cabot Electric Company, of Boston, propose to exhibit dynamos, motors, controllers and indicators of their special make, and of various design. They will also have on view other apparatus and supplies of their own manufacture.

The American Carbon Company, of Noblesville, Ind., will have a fine display of their various carbon specialties. The exhibit will be in charge of Mr. E. F. Peck, who is their New York agent.

The Bradford Belting Company, of Cincinnati, will exhibit their "Monarch" insulating paint and their "Dynamo" belting.

J. C. Vetter & Co., of New York City, will have a very interesting and complete exhibit in electro-therapeutics. It is intended to illustrate the flexible application and perfect control of the current in this field, and will include the Vetter current adapter, Vetter carbon current controller, Vetter volt selector, and standard milliammeter. A new feature will be the volt selector, which enables a medical practitioner to take voltage of any desired figure from the regular 110-volt current. The concern will also demonstrate the application of the current for cautery purposes.

Mr. T. H. Brady, of New Britain, Conn., will be in New York next month with his entire line of mast-arms, hoods, brackets, storm protectors, etc. A special novelty to be shown is his new arc cut-out box.

The Payne Engine Company will exhibit one of their 50-horse-power high-speed engines, direct connected to a 25-kilowatt Cincinnati Card dynamo. The engine will embody all the latest improvements of the company, including a new shaft governor, and the automatic circulation of oil on the main bearing.

The Kennedy Valve Manufacturing Company intend to exhibit a line of their high-pressure valves, designed especially to meet the requirements of modern electric light and power plants. This exhibit will consist chiefly of their extra heavy gate valves, iron body, bronze mounted, with self-packing stems; and of their patent renewable copper seat globe valves. The distinctive feature of the latter is that they are the only globe valves in which the seat can be removed and renewed without withdrawing the valve itself from the line of piping. The company will also have on view a line of their standard goods, the whole exhibit occupying about 100 square feet.

The American Stoker Company, of Dayton, O., will have one of their stokers placed in position on the floor feeding coal. It will show the distribution of coal over the grate surface, the driving mechanism, and the ease and simplicity of the actuating movements.

L. Katzenstein & Co., of New York City, will make an exhibit of their metallic packing for piston rod and valve, stem stuffing boxes, flexible tubular metallic packing for slip joints, improved slip joints, and metallic gaskets for all kinds of flanges.

The Columbia Incandescent Lamp Company, of St. Louis, will make an effective exhibit, although President Rhotehamel declines to disclose its exact nature for the present. All the company's specialties in lamps are to be in use.

The R. D. Nuttall Company, of Allegheny, Pa., will make an exhibit of their various electric railway specialties.

Huebel & Manger, of Brooklyn, manufacturers of electrical and brass goods, will have a neat display of their various specialties.

The Standard Paint Company will have a very interesting exhibit of their P. & B. products in the line of insulating paints, illustrative of the uses made. They will also have an excellent display of the "Ship" cored carbons of Schiff, Jordan & Co., of Vienna. The whole exhibit will occupy not less than 250 square feet.

Chapin Douglas Electric Company, 136 Liberty street, New York City, will exhibit a full line of the specialties manufactured by them, including the "Perfection" dynamo brushes, made of gauze copper wirecloth. These brushes are wound in such a way that contact is made on the end of all the wires, and there is no loose end to cause sparking. The brushes are very compact. Their C.-D. rosette, recently illustrated in this paper, is new and differs from others in the contact and mode of holding the cap to the base. Burnley's soldering paste is a new soldering flux, which is non-corrosive and contains no acid. A number of joints will be shown which will illustrate its utility in soldering wires. As agents for the well-known firm of Eyanson & Armpriester, the Chapin Douglas Electric Company will have in their exhibit a switchboard with latest designs in switches and instruments, including the Eyanson quick-break switch.

The E. T. Burrowes Company, of Portland, Me., will have an attractive display, including models of both their open and closed car curtains in pinch handle and cable styles; also a full line of curtain materials and fixture accessories. They will also exhibit the application of their waterproof material called oakette, which has proved very durable for open car curtains.

The Stanley Electric Manufacturing Company, of Pittsfield, Mass., expect to have in their exhibit at the approaching exposition one of their generators, with all the various parts shown separately; an exciter, a two-phase motor, a number of transformers, and a lot of switchboard apparatus.

A. K. Warren & Co., of New York, will have one of the most interesting exhibits, as it will show up the internal mechanism of apparatus, and give the public an idea how dynamos and motors get damaged and how they are repaired. The processes and materials will be practically illustrated. The company will also exhibit their brass alloy woven wire brushes, and a new brush holder, which they have lately perfected. They will also show in operation the machine used for turning down and smoothing rough commutators, and in a general way will exemplify the class of work that has to be done on emergency calls.

Eugene Munsell & Co. will lay before the public gaze a large display of mica in all its various forms. The exhibit will include large samples of mica as it comes in rough from the mines, and in the sheet; mica segments for railway motors, and mica in the shape of electrical insulation for all manner of purposes.

The Walker Company, of Cleveland, will exhibit in the basement, among the larger apparatus, an 80-kilowatt direct connected generator which will be installed in the basement of the building as a part of the general power plant. This machine will be direct connected to a tandem compound Dick & Church engine, built by the Phoenix Iron Works, of Meadville, Pa. It will be one of their standard compound wound dynamos for isolated incandescent lighting work. On the main floor the company will make a further exhibit, consisting of miscellaneous appliances for railway and lighting work; and this will also be the headquarters for the distribution of their literature.

The Peru Electric Manufacturing Company will group their exhibit in a tasteful booth, in which will be displayed their Laclede and Hercules batteries, as well as a full line of the different shapes and styles of porcelain which they manufacture for electrical purposes.

Stanley & Patterson will have a nice exhibit, including their general electrical supplies, and as Eastern agents they will also display lines of goods made by the New York and Ohio Company, Brunt & Thompson, Indiana Rubber and Insulated Wire Company, and E. G. Bernard Company, these manufacturers representing respectively lamps, porcelain, wires and cables, and dynamos and motors.

The National Carbon Company, of Cleveland, will make a general display of their carbon goods.

The Riker Electric Motor Company, of Brooklyn, will exhibit a line of their standard goods, consisting of two or three motors, a direct coupled dynamo, and engine plant, and some of their 1896 fans.

Henry R. Worthington will exhibit a number of electrically driven pumps, which they manufacture, most of which are of new design. They will have in active operation an electric house tank pump, also several sizes of horizontal and vertical electric pumps, of special design for different services, including a triplex steeple power pump geared to an 80-horse-power motor. They will also show a number of interesting studies of hydro-electric machinery for elevator service, water works supply, fire protection, etc.

Partrick & Carter Company, of Philadelphia, will make an interesting exhibit sure to catch the public fancy, dealing as it will with domestic uses of the current. It will include working samples of their house and hotel annunciators, return call and fire alarm hotel systems; also a complete line of their bells and general apparatus, all in working order. In addition to these, they will have two or three cases for holding their smaller goods, so that the trade can examine the whole line, varied and extensive as it is. The company will have two or three representatives on the ground all the time.

The Fuel Economizer Company of Matteawan, N. Y., will make an exhibit of specimen castings of their Green machinery, showing the latest improvements, drawings and blueprints in regard to different installations now at work, and data will be given out on the subject.

Mr. Hugo Reisinger, New York, will exhibit (1) "Electra" high-grade Nürnberg carbons for arc lighting for direct current and alternating current lamps. (2) All descriptions of the very finest grade of microphone carbons used in the manufacture of telephones. (3) A large variety of the very finest grade of battery carbons. (4) Carbons used for searchlights, for the production of aluminum, and for the electric smelting of all kinds of ores. The "Electra" factory, whose product will be shown, was one of the first to make arc light carbons and is said to be by far the largest concern of the kind in Europe.

FROM NIAGARA TO NIAGARA IN NEW YORK CITY.

THE completion of the electric power plant at Niagara, and the recent contract made by the city of Buffalo for its delivery within the city limits, by June, 1897, makes it appropriate that the work should be signalized in some way at the National Electrical Exposition in May. With this end in view, the management have secured a beautiful model, made by Mr. G. R. Allen, of Philadelphia, for the Hon. Peter A. Porter, of Niagara Falls, to scale, under the direction of Dr. Coleman Sellers, of the Niagara River, the power house, the town, and the long discharge tunnel. The turbines are seen in actual play, operated by water from the canal and driving the big generators. The model is 12 feet by 4, and will be given a place of honor on the main floor. The happy thought has occurred that as little power is required to drive the turbines, it might be comparatively easy to switch on a modicum of current from the Falls plant and actually run the model with it, not as an ideal exemplification of what might be done, but more as a pretty tour de force. To get the circuit was the problem, but General Eckert, president of the Western Union Telegraph Company, has authorized Mr. A. S. Brown, the electrical engineer of the company, to place two of their ordinary copper commercial wires at disposal, for use every evening, say for an hour or so, when the weather conditions are normal. This is a generous offer evincing no small amount of public spirit, and does great credit to the company. Mr. L. B. Stillwell, of the Westinghouse Company, has been asked to co-operate with Mr. Brown in working out the details, it being the intention to use the Tesla two-phase system and Tesla two-phase apparatus. A further suggestion is to hang some American Bell long distance telephones over the exhibit and thus listen to the roar of Niagara while seeing the model driven by it; and steps are now being taken to realize this. Yet another really brilliant idea, suggested by Mr. Stillwell and quite likely to be executed, is to deliver some of the Niagara current to condensers and cable to Europe with it. Mr. Tesla is greatly interested in the whole project and is lending it his active assistance.

MR. EDISON'S PERSONAL EXHIBIT AT THE ELECTRICAL EXPOSITION.

Mr. Edison is already preparing a select personal exhibit for the National Electrical Exposition, and Mr. Luther Stieringer has kindly consented to give it his own attention for arrangement. Mr. John Ott, one of Mr. Edison's assistants at the Orange laboratory, is now putting the apparatus in order for display. There are 40 cases.

In telegraphy, Mr. Edison will show stock printers, the phonoplex, the quadruplex, American District system, train telegraphy, and his vote recorder, the first invention he ever made.

In telephony, he will show several varieties of apparatus, including microphones, the chalk transmitter, motograph receiver, etc. He will also show his interesting megaphone, odophone, etc.

In lighting, Mr. Edison will show his earliest incandescent lamps, first converter, models of systems of distribution, multiple carbon lamps, center pole lamps; first chemical meter; lamp Leyden jar; platinum lamp, etc.; also the first fixtures used.

In the line of power transmission, Mr. Edison will exhibit some very early motors and models of great interest.

Among miscellaneous exhibits may be named his pyromagnetic motor, etheroscope, tasimeter, stages illustrating the evolution of the bamboo filament, magnetic friction devices, early phonographs, his recent fluoroscopes and his latest phonographs.

He has also in course of construction four sets of apparatus with which experts from his own staff will give exhibitions of the Röntgen rays, so arranged that by using the fluoroscope put into their hands, people can inspect their own anatomy. The Crookes tubes will be mounted in connection with mercury pumps, so that in a rough way the process of lamp exhaustion will also be demonstrated.

UNITED STATES PATENT OFFICE EXHIBIT.

The United States Patent Office is arranging to make at the Electrical Exposition a fine display of electrical models, etc., which will be peculiarly interesting and instructive as bearing upon the growth and development of electrical invention. A special representative of the Patent Office will be in charge of this exhibit, which will be under the general care of the historical and loan exhibit committee.

A GOLDEN KEY TO OPEN THE EXPOSITION.

Gen. E. S. Greeley has kindly consented to loan for the purpose of opening the National Electrical Exposition, the gold telegraph key used by President Cleveland at the World's Fair in 1893. It is proposed that when Governor Morton closes the circuit through the key to the power plant, instead of signaling merely from floor to floor of the Exposition Building, a circuit shall first be made across the Continent and back, through Chicago and San Francisco. The action will practically not be less instantaneous, but it will graphically illustrate the speed with which electricity travels. It is proposed also to fire a signal cannon in the same way, at the same time, to announce the event.

ANOTHER LONG LIST OF EXHIBITORS.

The management of the National Electrical Exposition publish in our advertising pages a list up to Friday last of companies that have taken space. The names not already given in our reading columns are printed below. We are informed that a large number of concerns are still applying for space, and that considerable difficulty begins to be experienced in finding room for them: Anchor Electric Company, Boston, Mass.; Ashcroft Manufacturing Company, New York; Boynton Multivolt Battery Company, New York; Brush Electric Company, Cleveland, O.; Clonbrock Steam Boiler Company, Brooklyn, N. Y.; Consolidated Safety Valve Company, New York: Adam Cook's Sons; Curtis Hull Manufacturing Company, Hartford, Conn.; Electrician Publishing Company, Chicago; General Incandescent Arc Lamp Company, New York; Hall, Geo. P., & Son, New York; Hayden & Derby Manufacturing Company; New York Carbon Works, New York; Pass & Seymour, Syracuse, N. Y.; Searles, A. M., Chicago; Simmons, John C., New York; Taunton Locomotive Manufacturing Company, Taunton, Mass.; Warren Electric Company, Chicago; Watertown Engine Company, Watertown, N. Y.; Diamond Electric Company, Chicago, Ill.; Burhorn & Granger, New York; Buyers' Reference Company, New York.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

The 105th meeting of the Institute will be held at 12 West Thirty-first street, New York City, on Wednesday, April 22, at 8 p. m., when a paper will be read by Mr. D. McFarlan Moore, a member, of Newark, N. J., on "Recent Developments in Vacuum Tube Lighting," accompanied by experiments. The hall will also be lighted by these tubes.

"JACK OF ALL TRADES."

A New England friend sends us the following "dodger," issued by an electrical supply company in his vicinity, as an exhibition of unsurpassed versatility:

Also a full line of electric supplies, including bells of all kinds, batteries, electric fixtures, and a full supply of electric lamps at low prices.

Estimates furnished for electric lighting and bells, telephones, speaking tubes, and motor work. Satisfaction guaranteed.

All kinds of locks and keys made to order, and locks of all kinds repaired and opened. Light machine repairing and grinding. Axes, knives, scissors, and skates sharpened. Saws filed, lawn mowers sharpened, and a full line of trunks and bags sold at low prices, and made to order if desired, at short notice.

Clothes wringers and carpet sweepers of all kinds repaired and sold, also sewing machines repaired.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS, ISSUED APRIL 7, 1896.

Alarms and Signals:—

PRESSURE ALARM FOR GAS PIPES. F. S. Baker, Chicago, Ill., 556,534. Filed Jan. 17, 1895.
The terminals of the electric current are located within both ends of a two-limbed vessel containing mercury; the level of which varies with the pressure.

ELECTRIC INDICATOR FOR HOT JOURNAL BOXES. W. B. Chockley, Denver, Colo., 557,650. Filed March 15, 1895.
Details of construction.

Primary Batteries:—

GALVANIC BATTERY JAR. C. C. Dusenbury, New York, 557,779. Filed Dec. 23, 1895.
Provides an air-tight cover.

Storage Batteries:—

STORAGE BATTERY. A. F. Vetter, New York, 557,920. Filed Aug. 30 1895.
Consists of plates inclosing the active material and provided with downwardly inclined openings for the circulation of the electrolyte.

Conductors, Conduits and Insulators:—

INSULATOR. C. E. Peterson, Stratton, Neb., 557,600. Filed Nov. 11, 1891.
A metal rod pointed at one end, a spiral coil of wire secured to the opposite end of rod and retained in engagement with a screw-threaded insulator.

WIRE-CONNECTOR. C. H. McIntire, Newark, N. J., 557,690. Filed Feb. 15, 1896.
An oval metal tube slit longitudinally adapted to be twisted together with the inserted wires.

CONDUIT FOR ELECTRICAL CONDUCTORS. J. M. Kinney, Boston, Mass., 557,830. Filed Aug. 6, 1895.
A series of layers of paper first saturated with alum and coated with a mixture of bichromate of potash, glue and diatomite.

INSULATOR. H. W. Rappelye, Philadelphia, Pa., 557,881. Filed Feb. 24, 1896.
Employs a clamp to hold wire in position.

Dynamos and Motors:—

COMMUTATOR BRUSH HOLDER. R. Hirsch, Milwaukee, Wis., 557,678. Filed July 1, 1895.
Employs a spring controlled arm adapted to bear against the rear end of the brush so as to press the latter into electrical contact.

ELECTRIC MOTOR. I. E. Storey, Hornellsville, N. Y., 557,714. Filed Jan. 28, 1893.
A multipolar motor having a single field-magnet coil.

ARMATURE CORE. G. F. Packard, Fort Wayne, Ind., 557,869. Filed Dec. 26, 1895.
A laminated core of segmental punchings having apertured ears for the fastening bolts.

ROTATORY FIELD MOTOR. C. S. Bradley, Avon, N. Y., 557,957. Filed Sept. 30, 1895.
The method of regulating an alternating current motor consisting in increasing the capacity-inductance product of its secondary circuit or circuits as the speed increases. Primary and secondary windings are provided for the two members of the motor.

FRAME FOR DYNAMO MACHINES. F. Bain, Chicago, Ill., Design Patent, 25,365. Filed Dec. 24, 1894.

Electro-Metallurgy:—

ELECTROPLATING COPPER. W. B. Hollingshead, Bronxville, N. Y., 557,816. Filed Sept. 23, 1889.
A bath composed of 12 parts of ammonium cyanide, 61 parts of potassium tartrate (neutral), 27 parts of a mixture of water and oxide of copper mixed to a paste, and water.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. T. Reyman, New York, 557,606. Filed July 9, 1895.
Details of construction.

ADJUSTABLE INCANDESCENT LAMP HOLDER. E. Wade, Lawrence, Mass., 557,732. Filed July 1, 1895.
Details of construction.

SHADE FOR ELECTRIC LIGHTS. W. E. Robinson, Faribault, Minn., 557,888. Filed June 20, 1895.
A shade leaf adapted to clasp the globe of the lamp by means of a spring and clamp.

ELECTRIC ARC LAMP. H. E. Bradley, Pawtucket, R. I., 557,648. Filed Feb. 6, 1896.
Employs a star-wheel actuated by the weight of the upper carbon rod, in combination with a pendulum.

Miscellaneous:—

PRESSURE GAGE. T. M. Gordon, Cambridge, Mass., 557,989. Filed June 7, 1895.
An electrical terminal in continuous contact with a pointer, and a plurality of holes spaced apart throughout the length of the dial plate. Designed to give an alarm.

WINDING DEVICE FOR ELECTRIC CABLES IN ELEVATORS. D. E. Houser, Fort Wayne, Ind., 557,819. Filed Aug. 16, 1895.
Provided with a series of annular contact rings adapted for engagement with corresponding series of brushes, arranged in the signaling circuit.

Railway and Appliances:—

ELECTRIC RAILROAD. W. R. Elliott, Chicago, Ill., 557,657. Filed June 27, 1895.
A magnet adapted to be used on an electric car for actuating a contact-making device.

CLOSED CONDUIT AND APPLIANCE FOR ELECTRIC RAILROADS. W. R. Edelen, Washington, D. C., 557,784. Filed Nov. 16, 1895.
Consists of a series of covers having no visible opening, manipulated through the medium of a tilting cover, operated by a shoe attached to the car.

ELECTRIC CAR TRUCK. C. F. Baker, Boston, Mass., 557,535. Filed Sept. 16, 1895.
Comprises an outer and an inner frame with longitudinal spaces between them at the sides.

TROLLEY MECHANISM. J. M. Kennedy, Hollidaysburg, Pa., 557,827. Filed Nov. 23, 1895.
A trolley having adjusting means operated from the interior of the car.

HANGER FOR TROLLEY WIRES. W. A. McCallum, Avondale, O., 557,860. Filed June 24, 1895.
Details of construction.

ELECTRIC PROPULSION OF CARS. A. H. Brintnell, Toronto, Canada, 557,960. Filed May 1, 1895.
A system in which the motor is composed of drum armatures and employing field magnets located at requisite distances apart between the rails of the track.

ELECTRIC RAILROAD BOND. B. Ford and W. Jens, Johnstown, Pa., 558,016. Filed July 22, 1895.
A rail having integrally attached thereto a flexible extension, having at its free end a head for attachment to an adjacent rail.

Switches, Cut-Outs, etc:

AUTOMATIC ELECTRIC RAILWAY SIGNAL. W. W. Alexander, Kansas City, Mo., 557,749. Filed Dec. 10, 1889.
A power train of wheels, operating simultaneously a semaphore, and a message transmitting device.

ELECTRIC SWITCH. A. K. Dresher, Worcester, Pa., 557,777. Filed April 24, 1895.
Employs a long and short spring and wedge cams.

ELECTRIC SWITCH. P. E. Marchand, Ottawa, Canada, 557,848. Filed Nov. 2, 1895.
Designed primarily to bring into circuit two or more lines.

Telegraphs:—

AUTOMATIC BATTERY REVERSER. P. Minnis, Mobile, Ala., 557,854. Filed Feb. 17, 1896.
The reversal, whether by accident or otherwise, of a battery at either end of a line, or an intermediate battery, will cause corresponding reversal to take place automatically in all batteries in series with the line.

Telephones:—

TELEPHONY. W. C. and J. M. Lockwood, Brooklyn, N. Y., 557,588. Filed Oct. 29, 1894.
A variable resistance for telephone transmitters, consisting of two flat flexible plates, as diaphragms, with flat electrodes lying thereon, and surrounded by carbon granules.

TESTING APPARATUS FOR MULTIPLE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 557,708. Filed June 19, 1888.
Provides an induction coil or converter in the circuit of each line so arranged in connection with a generator that an alternating or pulsatory current of low electromotive force shall be normally induced upon each circuit.

TELEPHONE TRANSMITTER. W. L. Wilhelm, Buffalo, N. Y., 557,741. Filed Nov. 21, 1895.
A mouthpiece provided with two branch tubes.

LOCK-OUT SYSTEM FOR TELEPHONE LINES. C. E. Scribner, Chicago, Ill., 557,898. Filed July 22, 1895.
Employs a telephone-switch and two electromagnets.

MULTIPLE SWITCHBOARD FOR TELEPHONE EXCHANGES. M. G. Kellogg, Chicago, Ill., 11,529. Reissued. Filed July 31, 1888.
A metallic circuit subscriber's line normally disconnected from the ground at the subscriber's station, in combination with a calling generator in the circuit of said line at the subscriber's station and a switch co-operating with the normally open ground to close the same while the generator is being operated.

LEGAL NOTES.

A SUIT AS TO FINANCING THE DETROIT ELECTRICAL WORKS.

A special dispatch of March 28 from Detroit says:—Two years ago the Detroit Electrical Works, of which Hugh McMillan was president, became financially embarrassed, and a circular was sent out to the stockholders, many of whom lived in the East, saying that there were only two courses open to them, to submit to foreclosure of a mortgage for $185,000 held by Mr. McMillan, or subscribe more capital. The stockholders were unable to supply the necessary funds, and the works were sold under foreclosure, Mr. McMillan bidding them in for the amount of his claim.

Mr McMillan then entered into a contract with William A. Boland, of Boston, and Frank A. Barnabee, of Providence, to recapitalize the company and enter into a partnership. By the terms of the contract, on the reorganization of the company Mr. McMillan was to receive $200,000 in preferred stock to cover his $185,000 interest in the defunct concern, and was also to receive $350,000 in common stock, which he was to hold in trust for the old stockholders. After making the contract, the Eastern capitalists investigated the affairs of the company, and, finding them unsatisfactory, concluded to stay out.

Mr. McMillan assigned his interest to Louis Warfield, secretary of the company, and William A. Jackson, who brought suit against Boland and Barnabee for breach of contract. The suit was ended in the Wayne Circuit Court this morning, and the jury awarded the plaintiffs a verdict for $283,750. The case will be appealed.

BRUSH STORAGE BATTERY PATENTS SUSTAINED.

A decree has been granted by Judge Colt against the Hopedale Electric Company and Milford & Hopedale Electric Street Railway Company for infringement of the Brush patents now owned by the Electric Storage Battery Company, of Philadelphia. These companies tried some years ago to make a road run with batteries of their own manufacture.

MISCELLANEOUS.

THE DIEHL MFG. CO. AND ITS NEW APPARATUS.

THE new Diehl arc lamp, illustrated in the accompanying engraving, is a clutch wheel lamp and has no dashpot to stick or main magnets to burn out. The clutch is applied to the periphery of the wheel; therefore, the rod is less liable to stick when dirty than is a lamp with clutch working directly on the rod.

The new lamp, Fig. 1, has a striking mechanism that is a positive innovation. This striking magnet is composed of a few turns of course wire placed in the main circuit. When current is turned on the lamp this magnet is energized and pulls the core of the shunt armature down. It holds the core in this position until it is weakened by the arc lengthening, then it releases the core of the shunt magnet and allows it to go up to the feeding point. The armature is then practically out of the field of the striking magnet and the arc depends entirely on the shunt magnets for regulation. This is a most valuable feature, as it does away with the weak point of a shunt lamp, namely, not striking a proper arc when current is turned on.

The adjustable chuck carbon holders take in any size of carbon from ¼ inch to ⅝ inch in diameter. The lamp is claimed to have fewer parts than any other lamp made. All parts are made interchangeable. The lamps are made in a variety of exclusive ornamental designs, and the out-door lamps are made water-proof without the use of a hood.

The Diehl Manufacturing Company, of Elizabethport, N. J., have also just brought out a complete line of dynamos and motors possessing a number of novel features.

The dynamos and motors are of the type shown in the illustration, Fig. 2, which shows the machine direct connected to a Case engine. This installation is on board the boat "Reverie."

The principle on which these machines are constructed is that of the armature encircling and revolving around the field magnets; this gives high efficiency combined with the slowest speed, insuring greatest durability, and dispensing with the necessity of countershafting, and the waste of power incident thereto. This slower speed, being due to the large diameter of the armature, is obtained without increase of weight and gives a starting torque proportionately great, at the same time increasing the efficiency by a diminution of friction of the bearings and the brushes.

The motors are fitted with self-aligning and self-oiling bearings and approved brush holders, thereby requiring a minimum of attention. The standard motors of 2 horse-power and under are bipolar; 3 horse-power and above are multipolar.

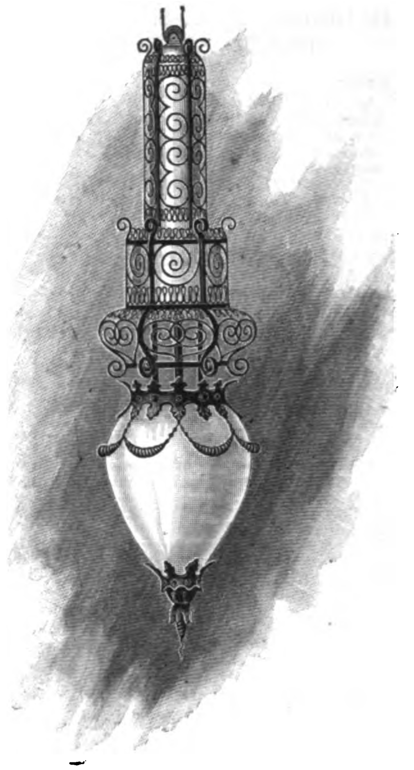


FIG. 1.—NEW DIEHL-KNIGHT ARC LAMP.

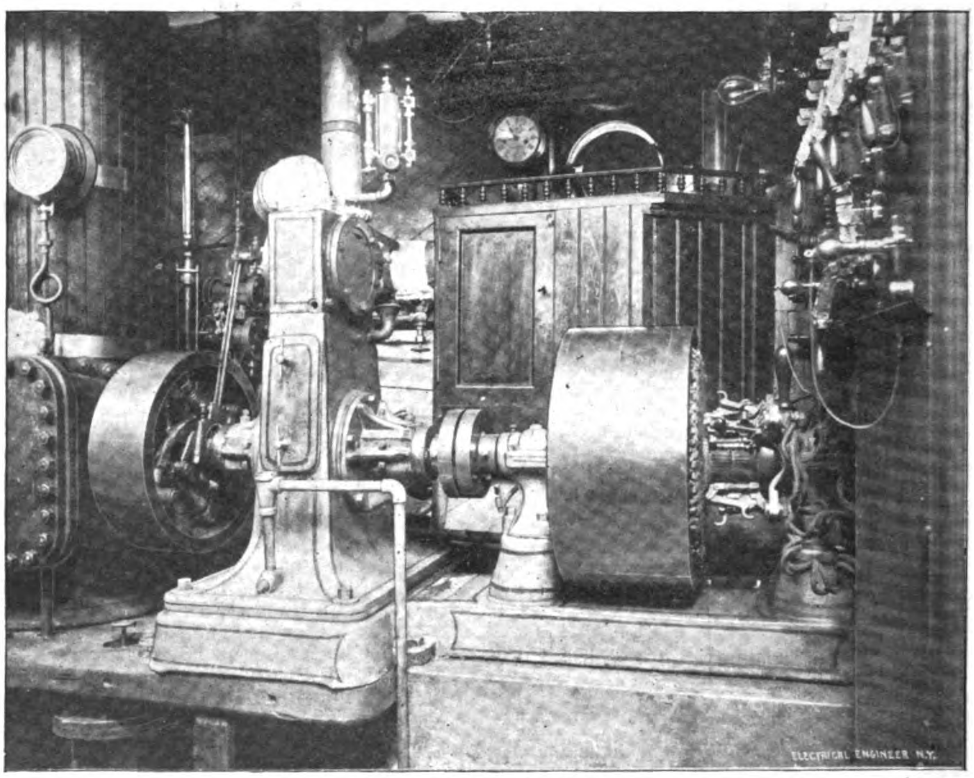

FIG. 2.—DIEHL DYNAMO DIRECT CONNECTED TO CASE ENGINE, ON BOARD THE "REVERIE."

In addition to their standard motors the Diehl Company are prepared to furnish estimates on motors for direct connection to special machinery.

Another unique product of the company is the Diehl electric balance wheel motor as applied to the shaft of sewing ma-

chines. The motor is entirely self-contained, and the field magnets are fastened to the arm of the machine. The armature carrier acts as a balance wheel, and is secured to the shaft by means of the regular clamp stop motion, thus allowing the release of the machine when used for winding bobbins. The combination takes up very little more space than the ordinary balance-wheel.

The speed is kept under perfect control by means of a small brake and rheostat operated by the treadle. The motor is constructed with as much care as the larger ones, and the finish adds much to the general appearance of the machine. This design of motor is manufactured in two sizes, one for family use and one for manufacturing.

The Diehl Manufacturing Company, which is manufacturing this apparatus, and which has its factory at Elizabethport, N. J., is a strong organization. It takes over the old business of the Diehl Company, whose ingenious apparatus is chiefly, if not wholly, the design of the clever inventor, Mr. Philip Diehl, mechanician of the Singer Sewing Machine Works, who is well known to all our readers. Hitherto the company has not built any generators larger than 20 horse-power, but it will now make all sizes up to 100 horse-power for all purposes of light and power, its specialty being direct coupled generators. It will also turn out large quantities of its ceiling and propeller fans, in which field it was a pioneer, and it will also manufacture its novel balance wheel motor, its arc lamp, and other meritorious specialties. It has greatly increased its facilities and has added a fine outfit of the latest machinery and tools. Some idea of the scope of its operations may be formed when we state that there are already over 11,000 of its suspended electric fans in use.

The president of the Diehl Manufacturing Company is E. H. Bennett, Jr.; vice-president, Philip Diehl; secretary, H. S. Miller, and treasurer, J. A. Reid. Mr. John C. Knight, well known as an arc lamp inventor, will be in charge of that important department, which will produce lamps of his latest design. The selling office at 561 Broadway, New York, will be in charge of Mr. B. C. Kenyon, as manager of sales, and Mr. C. A. Bramhall will be its representative. Mr. M. T. Lindenburg will be in charge of the Boston offices at 128 Essex street. The agencies will be as follows: Philadelphia, Vallee Bros.; Texas, Waco Electric Supply and Cons. Company; New Orleans, Southern Electric Manufacturing and Supply Co.; Birmingham, Ala., Harris & Wilkenson; Indiana, Frank J. Fox, Indianapolis; Richmond, Va., A. Pizzini, Jr., Norfolk, Va., J. L. Belote; Wilmington, Del., C. R. Van Trump. Other agencies are rapidly being established, and the company looks forward to doing a large business.

THE CENTRAL UNION TELEPHONE BOND ISSUE.

Speaking of the proposed issuance of $1,600,000 twenty year bonds at 6 per cent. by the Central Union Telephone Company, the "Chicago Record" says:—These are offered pro rata to stockholders at 97½. This bond issue was made necessary by the competition which the Central Union Company has encountered during the last fifteen months. The exchanges of the company are almost all in small towns, where competition is easy. The expiration of patents and recent inventions have put many telephone companies in the field, and the auxiliary Bell concerns, which once enjoyed a monopoly on the industry in their various districts, are now obliged to lower their tariffs and sometimes practically furnish service free in order to exist.

This condition of things has obtained in several towns in which the Central Union Company operates, and the statement for 1895 showed net earnings of $355,165, against $405,988 in 1894. In 1895 also a floating indebtedness of about $800,000 was accumulated. With new bonds it is proposed to wipe out this debt, to make extensions into new territory and prepare against competition by furnishing the best service obtainable. In Indianapolis and Columbus it is necessary to put many wires under ground. It is believed that good return will be received from extensions planned, although many are aware that the telephone industry in the smaller cities and towns of this country is just now in a precarious state. In a large city the conditions are very different, for the magnitude of the exchange is a guaranty against competition and the best assurance of the continuation of a monopoly. A large portion of the floating indebtedness is owed to the Bell Telephone Company, and it is said this corporation is willing to accept bonds at 97½ in settlement of its claim.

The authorized capital stock of the Central Union Company is $10,000,000, of which $6,605,300 is now outstanding. No bonds have been issued. The company controls the Bell patents in Indiana and Illinois excepting five counties, in Ohio excepting Cleveland and Cincinnati and in Des Moines, Davenport, Dubuque, Cedar Rapids, Keokuk and Ottumwa, Iowa. The company pays dividends of 5 per cent.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

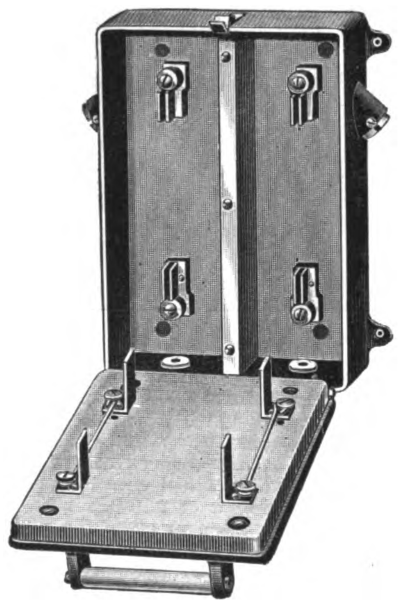
KOKOMO TELEPHONE APPARATUS FOR GRAND RAPIDS MICH.

We note the following from the Grand Rapids "Democrat": "After a long, exhaustive contest the Executive Committee of the Citizens' Telephone Company last night awarded the contract for 1,800 telephones to the American Electric and Telephone Company, of Kokomo, Ind. The contest has waged almost continuously for the past four weeks, with representatives of a dozen of the largest telephone makers in the country in attendance. Messrs. Fisher and Ware, of the Citizens' Company, were desirous of obtaining the best instruments to be had and it was largely due to their caution in this regard that the awarding of the contract was so long delayed. The machines selected embrace the full long-distance equipment and every modern improvement. General Manager P. C. Burns and Special Agent S. J. Bear signed the contract in behalf of the Kokomo concern. Shipping of the 'phones will begin in about two weeks and it is expected that the new exchange will be ready to respond with the familiar "number, please," about April 15. The 1,500 subscribers already secured cannot, however, all be supplied before May 1. The contract placed last night is the largest ever awarded by an independent exchange in America and represents a cash outlay of nearly $35,000. The Kokomo Company is also supplying the switchboard equipment."

THE BRYANT HIGH-TENSION SERVICE SWITCH AND CUT-OUT.

Encased in an iron box lined with slate thoroughly impregnated with oil and absolutely moisture-proof, this high tension switch makes the most perfect combination for 500 and 1,000-volt service cut-out. The principle observed in the well-known K. W. cut-outs, namely, fuses placed in the cover, forms one of the valuable features in this new device offered to the central station manager.

This service box is in reality a 100-ampere double pole, double break switch, with cut-out combined, with the further advantage of being entirely inclosed and protected when the current is on.



BRYANT HIGH TENSION SERVICE SWITCH.

To insert the fuses, the cover is opened, and the clips, between which the fuses are to be placed, become dead, and the operation is attended with no danger.

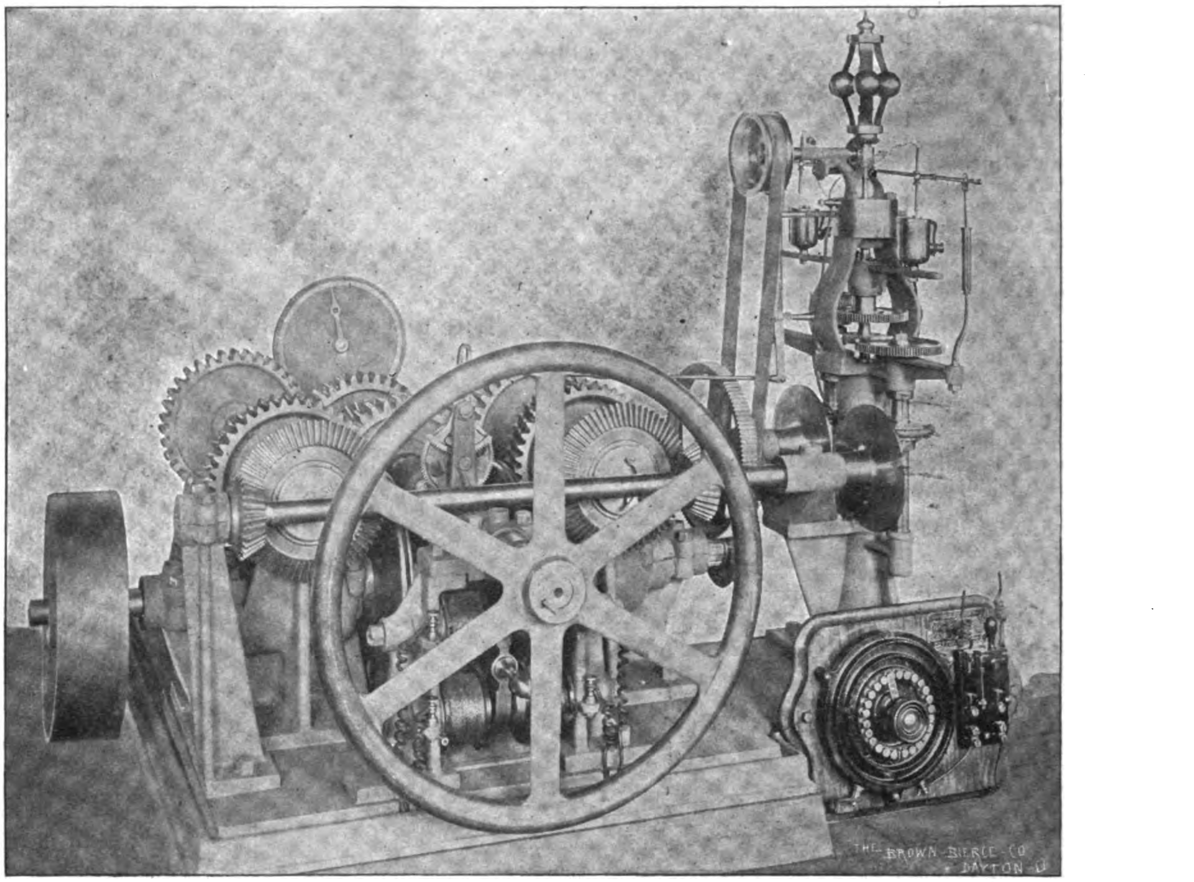
The switch is adapted not only for the primary side of alternating circuits, but equally well for 500-volt motor circuits.

The box has been approved by the fire underwriters. The Bryant Electric Co., of Bridgeport, are now prepared to deliver these switches.

THE GIESLER ELECTRO-MECHANICAL WATER-WHEEL GOVERNOR.

THE Stilwell-Bierce & Smith-Vaile Company, of Dayton, O., have realized for a long time that no governing device for water-wheels brought out up to this time was at all adequate to take care of the sudden and material changes in load and maintain a uniform speed. Formerly a variation of speed of 5 to 10 per cent. was permissible in ordinary mills. Now, with electric generators, a variation of not exceeding 1 per cent. is desired. During earlier experiments, efforts were directed to making a governor entirely electrical, that is, one which should use the change in the electrical current as a medium for governing the water-wheel employed in generating that current; but the results were unsatisfactory. Very fair results were obtained by the use of a hydraulic piston, but there were objections to this form in actual practice, and they were expensive to build and maintain as well.

After experimenting in every direction, they finally settled to the conviction that the form adopted and as shown in the accompanying cut was decidedly the most desirable in every way. With this machine, the slightest variation in speed is instantly multiplied to any desired extent, and enables them to open or close the water-wheel gate long before the ordinary balls would show any sign of moving. The governor can be arranged so as to fully open or close the water-wheel gate in from three to fifteen seconds, according to the requirements of the situation. The makers are enabled to use very small balls in this governor, because the balls are relieved of doing any work whatever. These balls and their attachments are all balanced to the finest degree possible, and their movements magnified to such an extent that the slightest variation in centrifugal action will at once manifest itself by directly opening or closing the water-wheel gate as required.



THE GIESLER ELECTRO-MECHANICAL WATER WHEEL GOVERNOR.

THE EXCELSIOR ELECTRIC COMPANY have moved back to the Boreel Building, on Broadway. It seems like old times to find them there again. President Fuller and his associates have the best wishes of the trade for another period of prosperity and for the sale of more than ever of their excellent generators, motors, platers, depositing dynamos and lamps.

NEW OFFICES OF THE STANDARD PAINT CO.

THE Standard Paint Company, the well-known manufacturers of P. & B. Paint, and the sole selling agents in the United States for Ship carbons, manufactured by Messrs. Schiff, Jordan & Co., of Vienna, have this week moved into much more commodious quarters at Nos. 81-83 John street, New York City.

For some time past the Standard Paint Company have felt that their past quarters were much too small for the prompt conduct of their business, and have now moved into new quarters on John street, which will give them a great deal more room for the transaction of their rapidly growing business.

On the first floor are stored samples of their P. & B. paints and paper, and in the back are the general offices for the transaction of their regular business. Mr. F. S. De Ronde, who has been associated with this company for many years, has his private office on this floor, and takes entire management of the sales department, both of the P. & B. goods and the carbon department. One flight up Mr. Shainwald has a handsome suite of private offices, and has fitted them up in a very handsome and attractive manner.

Behind these private offices are two departments divided off by railings, which formed a prominent feature of their exhibit at the World's Fair some years ago; and in one of these will be found Mr. Vandewater, well known to all newspaper men as a designer of the many attractive advertisements which the Standard Paint Company are in the habit of using.

The Standard Paint Company are to be congratulated on the necessity for finding these much more commodious quarters and on their selection of such a convenient and well-arranged office and store.

SALE OF THE BAXTER MOTOR WORKS.

The Baxter Electric Motor Works, Baltimore, have been purchased by Mr. Benjamin F. Deford for $25,000. Mr. Deford made the purchase as the representative of the bondholders' committee of the property. It has not been determined what disposition of the works will be made. A meeting of the bondholders will be held next week to consider the subject.

FIREPROOF LIGHTING AND STREET RAILWAY STATIONS.

FIRE in an electric generating plant is most destructive. In nine cases out of ten the cost of the equipment is ten times the cost of the building, and in case of fire the machinery is generally ruined beyond repair. The building is but a small per cent. of the total outlay. For a very small extra expense, these buildings can be made absolutely fireproof. The internal arrangement requires little or no wooden fixtures. If the walls are made of brick, and wood is eliminated from the roof, the plant becomes absolutely fireproof, for the reason that there is nothing about the construction to burn. Nothing, we may say, is fireproof, but if a plant is so constructed that there is nothing about it to burn, why is it necessary to carry any insurance? Corrugated iron will condense moisture on the underside, and, therefore, many power plants are built with steel trusses, covered with plank and slate. The Berlin Iron Bridge Company, of East Berlin, Conn., however, are able to build a roof for power plants made of corrugated iron covering, which will not drip from the underside in extremes of temperature. This construction has not a particle of woodwork about it. There are a large number of these stations now in use, all giving entire satisfaction. Parties contemplating work of this kind would do well to communicate with the Berlin Iron Bridge Company in this matter.

THE BELKNAP-CHAPMAN AUTOMATIC CONSTANT POTENTIAL REGULATOR.

FOR many applications of electricity a constant potential is an imperative necessity. The operation of a plant of incandescent lamps is a case in point. All the difference between financial success and failure of a plant may frequently be traced to good or bad regulation at the generators. A variation of only a small per cent makes an enormous difference in the life of the lamps.

The operation of most systems of power transmission also demands constant potential to be maintained at some part of the system and it is not infrequent to find in the power stations of to-day a man constantly employed watching the voltmeter and making hand regulation to counteract the changes that are constantly occurring. The compound winding of the generator does not remove the difficulty. A change of speed changes the voltage, the compounding does not compensate for that, and furthermore if the speed is constant and the compounding is therefore supposed to secure perfect regulation there is sometimes a considerable discrepancy, owing to two different causes. One of these is the change of temperature of the coils and the other is the hysteretic quality of the iron of the field magnet.

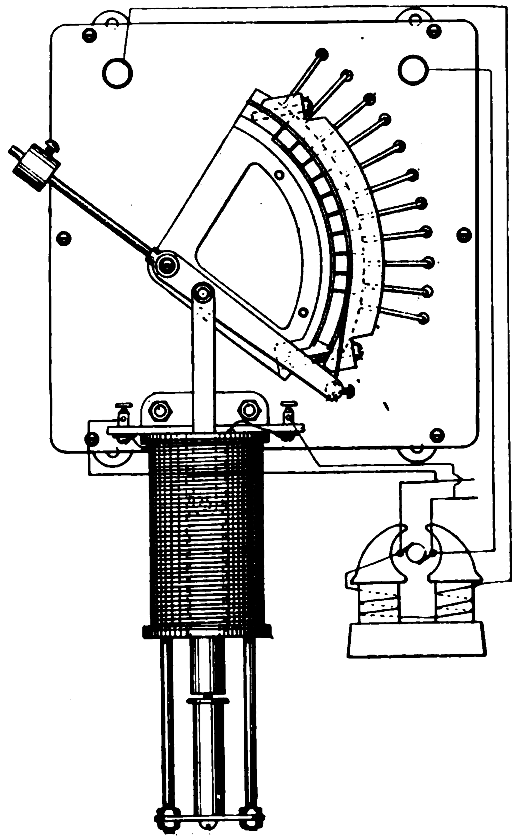
A generator running at exactly its normal speed and normal load may at one time develop a voltage higher than the normal and at another time a voltage lower than the normal according as the conditions of load have previously been higher or lower. The best of generators give a higher voltage when running on the strong side of the hysteresis loop than when running on the weak side, and no compounding can remedy the difficulty.

A perfect automatic regulation can only be secured by something outside of the machine itself, and recognizing this fact the Belknap Motor Company, of Portland, Me., have brought out a regulator which is shown in the accompanying engraving and one which is meeting with unqualified success both on account of its effectiveness and its extreme simplicity.

The invention originated with W. H. Chapman, the company's electrician, in connection with a lighting plant operated by water power at Bar Mills, Me. The water-wheel had no governor and the changes of load were such as to cause the speed at the dynamo to vary from 900 to 1,400 r. p. m. when no change was made at the water-wheel gate. The regulator shown was devised and applied with perfect success and in spite of these extreme variations in speed, the potential is kept within 1½ volts of the required point on the 110-volt circuit.

The device consists essentially of a field rheostat and a solenoid to operate it. The resistance coils are mounted on mica covered pipes placed inside of an iron box with slate front. On the front of the box is mounted a series of contact segments connected to the resistance coils and arranged in the arc of a circle, at the center of which is pivoted a lever. One arm of the lever carries a stud and contact brush that moves over the peripheral surface of the segments. The other arm of the lever carries an adjustable weight, by which the voltage may be adjusted to any desired point, and the regulator will then keep it at that point. The resistance is connected into the shunt field circuit and the contact brush short circuits more or less of it, according to its position.

The solenoid that operates the lever arm is built large, so as to make the friction of the moving parts enter as a small factor of the total power of the solenoid, and the solenoid and its core are of such proportions that the lifting force through a range of a couple of inches is almost exactly constant. A solenoid constructed to expend 55 watts is found to operate this style of rheostat on changes of 2 per cent. in voltage, and larger solenoids operate with greater accuracy. The solenoid



THE BELKNAP-CHAPMAN CONSTANT POTENTIAL DYNAMO REGULATOR.

is connected as a shunt to the armature circuit, and may be connected to the potential wires that lead to some distant point of the system, and the apparatus then makes allowance for the loss in the line, and secures all the benefits of an overcompounded generator run at absolutely steady speed, even though it actually be attached to a plain shunt machine and that machine be run at a speed varying 50 per cent. or more.

This method of regulating is not only adapted as a perfect supplement to the compound winding, but also to entirely displace it.

FERRACUTE MACHINE CO.

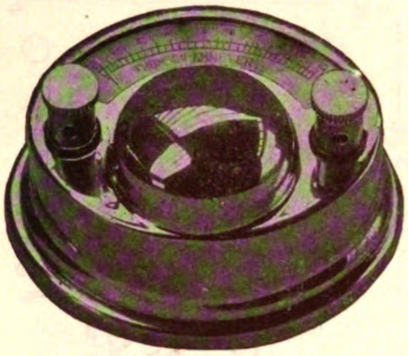
The Ferracute Machine Company, of Bridgeton, New Jersey, manufacturers of presses and dies and other sheet-metal tools, make a number of presses which are especially adapted for the electrical trade. They build several open front presses for cutting armature discs up to 20 inches diameter, as well as a number of round and square bed double-crank presses for large discs. This is the best form of press, it is said, for cutting circles for armature discs and for sections of large discs. This style of press seems very popular, the General Electric Company having seven of them, while several other firms are using them for electrical work.

They will be glad to give information about their armature disc cutting press for notching armatures from 3 inches to 36 inches diameter. They also make a number of sizes of punching presses for cutting out instruments and other work in heavy metals, which have proved popular for the electrical trade. They will exhibit at the Electrical Exposition in May, in New York, three or four of their presses, and will probably have them running with electric motors, manufacturing small articles.

They issue a handsome catalogue describing some 300 different presses; also a new sheet devoted to presses for special work, which they will be glad to send on application.

NEW G. E. POCKET AMMETER AND VOLTMETER.

THE introduction by the General Electric Company of the new measuring and testing instruments for alternating current work (described in our issue of March 25) has been followed by a development no less valuable along similar lines, and a set of ammeters and voltmeters has been especially designed for carriage in the side pocket of an ordinary coat. They are known as the Thomson pocket ammeter and pocket voltmeter. These pocket instruments give to the isolated plant engineer, the manager of the small central station and



NEW G. E. POCKET AMMETER.

the working electrician a cheap and reliable instrument which may be carried in the pocket and exposed to comparatively rough usage without the fear of impairment of accuracy.

The construction of these pocket instruments while suited to meet the different usage to which they are likely to be subjected, is similar in principle to that of the standard instruments. They are oval in shape, 4¼ inches by 3½ inches. Notwithstanding the singular compactness of the pocket instruments the scales are unusually long and clear. They are completely encased by a polished nickel cover. The ammeters are calibrated to read, 2, 10, 25 amperes, the voltmeters read from 0 to 75 and 150 amperes.

SPRING SUNBEAMS.

The Sunbeam Incandescent Lamp Company, Chicago, have received the following letter from the Wheaton Electric Light and Water Company, Wheaton, Ill.: "We have now several hundred of your 4 c.-p. lamps in use. They give as much light as an ordinary kerosene lamp and with them we have been able to displace kerosene in a number of places and also to retain some of our old customers that we otherwise would have lost. They are a success in every way and give us the best satisfaction."

CROWN WOVEN WIRE BRUSH CO.

Owing to increasing business, the Crown Woven Wire Brush Co., of Salem, Mass., have moved into the new Power's Block, near the B. & M. Railroad station, where they have a model factory, and hope to turn out even better goods than heretofore. The growth of this company's business is phenomenal, and is one of the results of making honest goods. Their Crown "K" brush, in particular, is meeting with great success. They are not only selling their brushes in the United States, but are sending them to Mexico and Canada, and hope soon to place them on the English market. Their new factory, which is especially adapted to their business, will enable them, not only to turn out brushes in larger quantities, but to compete with any goods in the world in quality or price.

"IN TIME OF DRIFTS PREPARE FOR DRAFTS."

The Electric Appliance Company have closed arrangements for the agency for the Dayton Electric Ceiling Fan, and have a complete line of these fans in operation at their salesrooms at 242 Madison street, Chicago. The Dayton Company make a very attractive line of these goods, including a handsome electrolier and column fan. Some of the special points claimed for the Dayton fans, aside from their artistic finish, are that they have four blades, run at a high speed, and have a very high efficiency.

NEW BRITAIN, CONN.—During a fire at the Russell & Erwin Mfg. Works, the flames were entirely prevented from spreading from one department to another, by the corrugated iron doors that were furnished by the Berlin Iron Bridge Co.

SOME REMARKABLE CARBON BRUSHES.

The Partridge Carbon Company, of Sandusky, O., have received the subjoined letter as to some of their carbon brushes that had run 50,000 miles. They had worn down only about three-quarters of an inch, very evenly and smoothly:

Point Pleasant, Mich, March 26, 1896.

Partridge Carbon Company, Sandusky, O.

Gentlemen: I send you to-day two motor brushes made by you and bought by us from Westinghouse Electric and Manufacturing Company, during July, 1894. These two brushes have been in use seven months, during which time the car from which brushes were taken, has made a mileage of about 48,000 to 50,000. The brushes sent are about the worst worn of a set of ten that I have in my possession. To me this is something extraordinary, as I have had the experience of seeing new carbon brushes put on motors every other night.

We are using Westinghouse No. 12, 20-horse-power motors. I would say that I originally bought 100 brushes and I have them all now, none having been used except the ten, as above, which are good for another 50,000 miles' run. I do not think there is another such brush on earth as the Partridge for long life, wear on commutator, etc.

I believe in showing appreciation of a good thing, hence my letter. Very truly yours,

SOUTH JERSEY STREET RAILWAY COMPANY,
Per P. T.

N. B.—Would say that our line runs along beach front, where sand and dust are in plenty.

NEW ENGLAND NOTES.

THE ANCHOR ELECTRIC COMPANY, 71 Federal street, Boston, report having closed recently their fiscal year. It was a year that on the whole was highly successful and far better than had been expected, leaving the current prospects admirable and very bright. The company have been enabled to declare a satisfactory dividend, besides laying by a good sum to reserve.

THE BEACON ELECTRIC COMPANY, of Boston, through the efforts of Mr. E. McOuat, their superintendent, have been making rapid progress with the manufacture of Crookes tubes and have already produced a large number in various designs, which have proved very successful. They are also now making a specialty of miniature incandescent lamps and series lamps, and have sold a large number of regular 16 c. p. lamps, with fleur-de-lis embossed on an opal glass, which gives a very pretty effect.

MEXICO CITY.—Mr. J. E. Torbet, of the Mexican Electric Company, has been appointed General Mexican Agent of the Beacon Lamp Company, of Boston, Mass., the Bryant Electric Company, of Bridgeport, Conn., and the American Electrical Works, of Providence, R. I. A full line of goods from these factories will be carried in stock at the offices and salesrooms.

WESTERN NOTES.

THE AMERICAN BATTERY CO., West Quincy street, Chicago, report that their business is still steadily growing, and that from the present outlook there is every sign of the increase in their output continuing at its present healthy rate. The American Company's batteries are well known through the country for giving most satisfactory results for lighting and other purposes where storage batteries are used. Amongst some of the recent contracts which they have closed was one with Gen. Joseph Torrence for sixty 600-ampere hour cells for lighting his private residence on the Lake Shore Drive, Chicago.

THE REITH ELECTRIC COMPANY has been formed at Chicago by R. D. Rowe, P. Reith and J. M. McNable, with a capital stock of $4,500.

THE ELECTRIC APPLIANCE COMPANY have just completed the successful installation of an electric light and power plant in their own building at 242 Madison street. The power is secured from a powerful natural gas engine, which also does the work of driving a large freight elevator. The plant is running nicely and producing a satisfactory light. The dynamo is assisted in accomplishing its results by the use of Paranite wire and Packard lamps. The switch-board is equipped with C. E. N. jack-knife switches and Whitney instruments.

BOWERS & BROS., Lake street, Chicago, have forwarded us a copy of their useful, new price list of cut and uncut India and amber mica, and of Billings & Spencer drop forged copper segments for dynamos and motors. It is comprehensive and gives full data.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. APRIL 22, 1896. No. 416.

Power Transmission.

ELECTRIC POWER IN BRICK YARD AND FOUNDRY.

BY F. M. TAIT.

ABOUT eight months ago the writer induced the Lehigh Fire Brick Company, of Catasauqua, Pa., to change over from steam to electric power, pointing out the great economy and superior advantages to be accomplished by throwing out their 65 horse-power engine and long line of shafting then in use. This has been fully demonstrated since the new plant has been in operation.

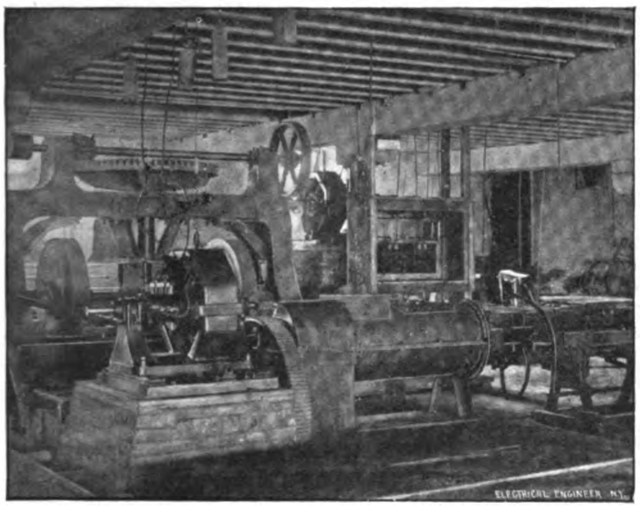
A 40 horse-power multipolar, 220-volt motor drives a 9-inch circular pan by means of gear wheel and pinion, as shown in the engraving Fig. 1. Suspended over the pan, but not touching it, are two heavy steel-tired wheels weighing 4,500 lbs. each. These wheels turn freely on shafts whose ends are free to slide up and down guide ways, thus allowing the wheels to be adjusted to any height above the pan desired, according to the fiber needed in finished brick.

The contents of small wooden cars carrying a mixture of brickbats, spar, fireclays, etc., in proper proportions, is dumped into the pan while it is in motion, carrying the raw materials under the heavy wheels, which commence to roll upon their shafts and mash down the mixture every time it comes around. Plough-shaped pieces properly set at various places in the pan, but not touching it, guide the mixture always under the wheels. Water is mixed with the materials in the pan from time to time until it resembles stiff mud. After being worked about in the pan for four or five minutes and proving properly tempered it is shoveled into the molding machine, shown in the foreground. A 25 horse-power, 220-volt motor of same type as the other drives the shaft of this moulding machine through gear and spur wheel, as shown.

On the shaft of this moulder are, arranged propeller-like blades, which revolve within the hollow cylinder and always force a continuous slab of fireclay through an opening at one end, called the die. This is cut off every four feet by one stroke of a lever, carrying a piece of piano wire, stretched taut, for a knife. Another lever forces the detached slab of tempered or finished fireclay against wires set vertically in a frame the exact distance apart required for finished brick, this operation making from nine to twelve brick, according to size. The cutting table is shown near the die on the moulder.

The bricks are then placed on a continuous running elevator, belted to the tempering pan shaft, and carried upstairs to the drying room, whence they go to the burning kilns. These kilns are fired by coal, using forced draft from a No. 6 Sturtevant blower direct connected to a 10 horse-power, 220-volt, electric motor at 1,250 r. p. m.

This arrangement shuts off the entire steam consumption in this plant, except in winter time, when a small boiler maintains ten to twelve pounds pressure for heating the buildings and drying brick. The economy and increased output of this plant is remarkable and interesting, from the fact that the motors are located 6,000 feet from bus-rods in our central station and have but 220 volts on 3-wire Edison circuits available for pressure. A polished slate switchboard, with main line switch, fuses and recording wattmeter mounted thereon, is placed in the office of the brick company and controls the wires entering the building to various motors. This arrangement allows the manager to tell at a glance what his power costs him to manufacture one brick, greatly facilitating close figuring, so necessary in these days of keen competition.



Electric Power in a Brickyard. (Crocker-Wheeler Installations.) Electric Power in an Iron Foundry.

I believe this is the first plant in the country manufacturing fire brick successfully by electricity.

Another plant, also installed by the writer, and interesting from the fact that it has effected great economy, was the installation of a 10 horse-power, 220-volt, electric motor to a drum arrangement for drawing cars heavily loaded with pig iron, coal, coke, etc., up an incline to charge the foundry cupolas in the well-known foundry and machine works of the Davies & Thomas Company, East Catasauqua, Pa. This motor is direct connected through a worm gear, and draws cars up a 12 per cent. grade with ease 120 feet per minute. The engraving, Fig. 2, shows a car with three tons of iron, outside of weight of car, ascending the slope to the cupola doors.

The cupola man operates this motor from the top by means of a street-railway controller. Conveniently placed near it is a lever for throwing in a clutch which connects the drum with the shaft of the gear wheel. Another lever controls a band friction brake around the edge of the drum and allows the empty cars to be run down the incline by gravity, first throwing out the clutch. As the current consumed is but for a few seconds while ascending, it is obvious the expense of

operating this motor is nominal. All current passes through a wattmeter conveniently located in the office of the iron company.

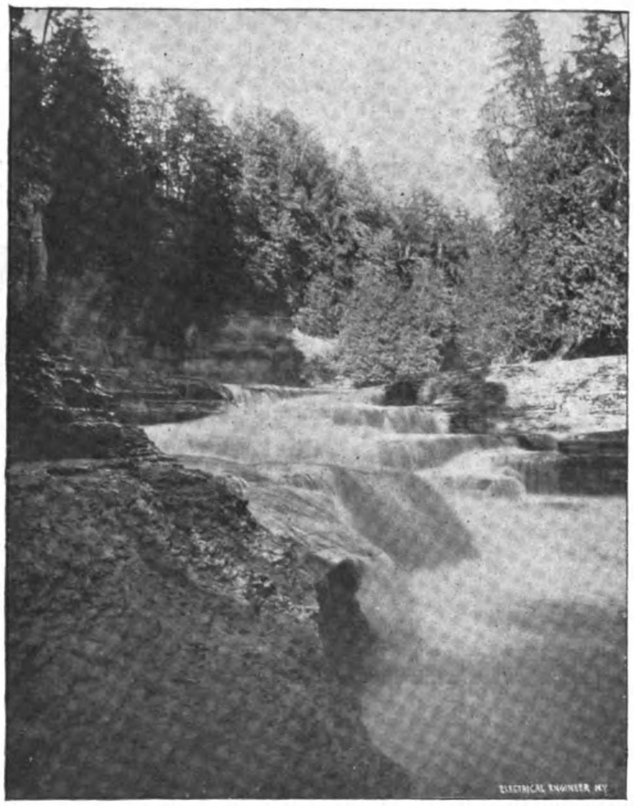
The raw materials previous to the installation of this motor were wheeled in barrows and small cars to the cupolas. The motor is snugly out of the way boxed in under the track and receives but little attention. It has been in daily operation almost one year. There are many other motor applications here, as usually found elsewhere, from that of clipping and cleaning horses to making ice cream, churning butter, etc.

THE TRENTON FALLS AND PROSPECT WATER POWER DEVELOPMENT.

BY ORRIN E. DUNLAP.

THE City of Utica and surrounding neighborhood seem very likely to be largely benefited by the development of the water power of the West Canada Creek at Prospect and Trenton Falls. The West Canada Creek has its source in the Adirondacks to the east of the villages of Prospect and Trenton Falls. It flows west, passing somewhat to the south of the village of Prospect, then makes a turn nearly at a right angle, flowing south to the Mohawk River, of which it is the principal tributary at Herkimer. The principal and most remote source of this stream is the group of lakes about forty miles northeast of Prospect, known as the West Canada lakes.

The power scheme projected is one of the most notable in the eastern part of New York State. From the fact that the



THE TRENTON FALLS.

forests surrounding the source of water supply are assured of preservation, and the locality surrounding the proposed points of power development is rich in markets for the power product, there seems every incentive to investment on the part of capital. The watershed is of the highest portion of the Adirondack wilderness, about 175 miles square, and has more than sixty lakes, having a total area of twelve square miles. The lowest of the lakes stands at an elevation of about 2,300 feet above the sea level and the lowest portion of the watershed is about 750 feet above the streets of Utica. It is from these lakes that the West Canada Creek flows for about forty miles, receiving along its source water through various tributaries. The largest of the lakes is the Honedega, formerly known as Jock's Lake. Near Prospect, as stated, the creek takes a sharp turn and flows nearly south for a distance of two and one-half miles, and on this part of its course there is a fall of nearly 500 feet. Further on down stream a mill utilizes the power from a portion of a fall, and from this point on to the Mohawk there is a fall of about 250 feet distributed along its course.

In response to a desire of capitalists, Mr. Wallace C. Johnson, M. Am. Soc. C. E., of Niagara Falls, has made a most thorough and careful study of the West Canada Creek locality and its power possibilities, and he has formulated a report most flattering to the project. Mr. Johnson is especially well qualified to consider such a subject in its entirety and with accuracy from the fact that he has had extended experience in hydraulic power matters and is at present the engineer of the Niagara Falls Hydraulic Power and Manufacturing Company.

In his extended report Mr. Johnson reviews the available rainfall statistics of the section and reaches the conclusion that at least two-thirds of the downpour eventually would, in such a thickly wooded section, reach the stream. This, he states, would produce a mean flow, in the average year, of 904.6 cubic feet per second. He finds that 1895 was the driest year in seventy years, and in that year Professor Scripture made a series of measurements at Morgan's mill, which is at the lower end of the 500-foot drop at Trenton Falls, and Mr. Johnson has calculated that in that dry season there was a flow of 357 cubic feet per second, or a little less than one-half the amount he estimates as the mean flow.

He concludes, therefore, that to be sure of maintaining the mean flow during the driest years, they must provide for an addition to the dry weather flow, at periods of lowest water, of a quantity equal to 390 cubic feet per second. This could be done by building a reservoir having a capacity of two thousand million cubic feet, which storage could be provided very cheaply in the watershed by placing low dams at the outlets to the several larger lakes and deepening the outlet so that the water can be drained a few feet below the present level.

For instance, he cites the case of Honedega Lake, stating that if a dam were placed at the outlet of that lake that would raise the water five feet and the outlet deepened so as to drain five feet below the present level, this lake alone would provide one-fourth of the amount needed. The raising of the lake levels would work no injury to the timber or other interests, but all the mills on the creek below the water power and all the mills on the Mohawk below the mouth of West Canada Creek would be benefited. The expense would have to be borne by the milling interest. It is Mr. Johnson's opinion that the Erie Canal could be conveniently fed from West Canada Creek.

Plan of Development.—Of the general plan of development and amount of available horse-power, Mr. Johnson says: "There is said to be a total fall in the stream, between Prospect and Trenton Falls, of about 500 feet. If the mean flow of the stream in dry years (740 cubic feet per second) were used under a head of 500 feet, it would be sufficient to develop upwards of 25,000 horse-power. In order that the supply of water to the wheels may be perfectly steady and reliable, it is necessary that the sufficient pondage be obtained below any mills which may be built to guard against any temporary checking of the flow of the streams by the acts of the mills above. It has been decided by the courts that the users of power from a stream have the right to retain the flow sufficient for its full use in their business, but not to a greater extent. The lack of railroad facilities and the general character of the country about Prospect preclude the idea of the establishment of any very great factories on the West Canada Creek above this point. A few sawmills have already been built and other industries of that character may in the future use the waters of this stream. The damming of the stream and the use of its waters for these purposes might stop or check its flow for a few hours; hence the necessity for a certain amount of pondage.

"An effective working head of ninety-five feet is all that can be depended upon. Seven hundred and forty cubic feet per second used under a head of ninety-five feet is sufficient to produce 6,400 horse-power, that is, 6,400 real and effective horse-power, on the shaft of the water wheels. This amount of power is sufficient to drive generating machinery having an output of electric energy equal to 6,000 horse-power. Power can be transmitted to the City of Utica with a loss not exceeding 10 per cent., which would give at the central station in the city an amount of electric energy equal to 5,400 horse-power.

"In designing the dam, canal and power house, I have kept in mind the fact that at some time in the future the additional rights controlling an additional head of 400 feet will probably be secured. The canal and the dam are located in the proper place for this larger development and would be used without any changes.

"The West Canada Creek, flowing as it does through a deep gorge, has not afforded an advantageous place for the building of mills, to use the power of the wheels directly. The

means of transportation, too, have been very limited. Within the past few years the transportation facilities have considerably improved by the building of the Adirondack branch of the New York Central and Hudson River Railroad, and the vicinity of the West Canada Creek, along some parts of the two and one-half miles of its course, within which the 500-foot fall occurs, now affords desirable sites for new factories. which could be supplied with power conveyed to their works by electricity, when the full 500-foot fall may be utilized. For the first development, which is herein particularly planned and estimated upon, a surer and more profitable field can be had than the supplying of factories, which might be induced to locate in this region."

Mr. Johnson then enumerates the power required by the electric light, railway and other local industries in Utica as showing the market available. In concluding his report, Mr. Johnson reviews the revenue to be expected.

The proposed method of development would be along lines similar to the plan of the Niagara Falls Hydraulic Power and Manufacturing Company. All masonry is to be of Trenton limestone. The gates of the head and the section of the canal are to be of proper size to carry 740 cubic feet of water per second with not more than one foot loss of head when the pond is three feet below the crest.

From the canal the water will be conducted to and along the power house, which will be one-story high, in two penstocks eight feet in diameter. To each penstock it is proposed to connect five turbine wheels of a capacity of 800 horse-power each, running on horizontal shafts. The floor of the power station, on which the wheels will stand, will be about twelve feet above the water level to be beyond the water at flood time. Draft tubes will be used to secure the remainder of the head. All generators will be direct coupled to the shafts of the turbines. The capacity will be such that one turbine and one generator of each set of five may remain idle for repairs or examination.

For a plant that could be quickly installed to light the City of Utica, Mr. Johnson recommends the use of three upright water wheels of 500 horse-power each geared to the same shafting connected to three generators, each of 350 kilowatts, and a line to deliver in Utica, fourteen miles distant, 850 horse-power; the pole line thus established to carry the line for heavier transmission when it is available.

A 21-MILE MUNICIPAL TRANSMISSION, RIVERSIDE, CAL.

THE California Electrical Works, San Francisco, have received the contract for the municipal lighting plant for the city of Riverside, but as yet the construction of same has not been commenced. They expect to commence the construction about May 10. The contract is for a transmission plant of twenty-one miles, the power plant being located on Mill Creek, about eight miles from Redlands, in San Bernardino County, and the city of Riverside rents its power from the Redlands Electric Light and Power Company, paying $3 per month per horse power, delivered at the sub-station in Riverside.

The Redlands Electric Light and Power Company have had their generators installed for nearly two years, but at the generating station will now be placed three 100-kilowatt step-up transformers, to raise the potential from 2,500 to 11,000 volts. There will be also a marble switchboard for 10,000 volts placed in the power station. The transmission line will be constructed of 30-foot round cedar poles, 6 inches tip. Insulators will be the Locke porcelain triple petticoat, guaranteed to stand 20,000 volts. The pins will be Locke indestructible steel pins. Cross-arms will be braced with iron braces throughout, and the size of wire will be No. 4 B. & S. gauge, bare copper.

In the sub-station at Riverside the California Electrical Works will place a 10,000 volt switchboard and three step-down transformers to step down from 10,000 to 2,000 volts, having a capacity of 250 kilowatts. The distributing switchboard will also be located in the sub-station, and there will be three 3-wire circuits to operate the incandescent and three 3-wire arc circuits to operate the arc lamps, run from this board.

The board will be constructed of marble and iron, and Whitney instruments will be used throughout. There will be 100 Helios alternating lamps used, ninety for street and ten for interior lighting. The town will be wired for about 1,000 incandescent lights for commercial purposes. The transformers will be of the Wagner type.

ELECTRIC POWER IN A BALTIMORE WOOLEN MILL.

The use of electricity in textile industries is rapidly widening, as its adoption is found to give to textile machinery the perfect regulation so essential to high-grade production. One of the most recent installations has been made in the mills of W. J. Dickey & Son, Baltimore, Md., by the General Electric Company. The electricity is generated by two 90 horse-power moderate speed generators, belted to a horizontal water-wheel. The current is transmitted about 200 feet to the third story of a woolen mill, where it will be used to operate motors and furnish light; in this third story thirty-six 60-inch woolen cards and four mules are to be placed, the cards being arranged in three rows, thirteen to a row, with a line of shafting to operate each row. The motors will be placed either on top of the roof beams or be suspended from the same beams by iron slings and will be connected to the line shaft by a belt. Two of these line shafts will be operated by two 25 horse-power slow-speed motors. For the operation of the mules a 20 horse-power moderate-speed motor will be connected to the shafting.

POWER TRANSMISSION IN VIRGINIA.

The Massie Light and Power Company has been formed in Virginia, with its headquarters at Charlottesville, Va. The capital stock is $50,000. Mr. W. J. Ficklin is president, F. B. Treiber secretary and treasurer. The main object of the company is not to furnish light, but power. The company have a water privilege about four miles from the city, and will transmit their current that distance. A dam is to be thrown across the river. The power building will be of stone and brick. The apparatus for power transmission has not yet been selected.

NIAGARA POWER TRANSMISSION.

THE New York State Superintendent of Public Works, with the consent of the Cataract General Electric Co., which has the exclusive right to occupy canal lands for the transmission of power, has granted a permit to the Niagara Power Company to construct a pole line from Tonawanda to Buffalo and from Tonawanda to Lockport, the poles to be placed upon the tow-path side at least 24 feet from the water line, the poles to extend to such a height above the ground that the sagging wires suspended between them shall at no point be less than 24 feet above the ground. At all points, where such line is carried over the canal the cables must be suspended from steel towers so that the sagging wires across the canal shall be at least 125 feet above the water line.

On April 11 plans and specifications were filed with the Board of Public Works of the city of Buffalo for the trunk line distribution in that city of Niagara power under the franchise accepted by the Niagara Falls Power Company, January 14, 1896. The line from Tonawanda to Buffalo will be over canal lines.

THE LYONS POWER TRANSMISSION SCHEME.

The Société Lyonnaise des Forces Motrices du Rhône, which proposes to utilize part of the water power of the Rhône for the generation of electricity for light and power, has awarded the contracts for part of the plant. The complete plant is expected to produce 20,000 horse-power, and will consist of 16 turbines of 1,250 horse-power each. The available fall varies from 30 feet to 40 feet. The turbines have vertical shafts and are of the reaction type, working with a suction tube, and the generators are connected direct to the vertical turbine shaft. By a special arrangement the large turbines can be made to run at 120 revolutions, while the turbines driving the exciter dynamos run at 250 revolutions. The generators are each to have an output of 1,250 horse-power. To start with, 8 turbines of 1,250 horse-power each, with generators and the necessary exciter dynamos with their turbines, will be erected, the dynamos being made by Brown, Boveri & Co., of Baden, the turbines by the well-known Swiss firm of Escher, Wyss & Co., of Zurich.

ELECTRIC POWER TRANSMISSION AT WALSENBURG, COLO.

For the machinery belonging to Mr. Spencer, a building will be erected on the property just west of the present electric light and power house at Walsenburg. After the building is completed, the machinery will be put in shape and started up. The electricity will be wired over to the Cameron and the Sunshine mines and will furnish them power at much less cost than it can be furnished by steam. The mines will also be lighted by electricity. Mr. Spencer belongs to a company that owns mining property and he says that it is their intention to develop it in the near future. His plant will furnish the power.

CALIFORNIA WATER POWER IN ELECTRICAL HARNESS.[1]

BY H. G. T.

SENATOR S. N. ANDROUS, of Pomona Valley, who has given the subject careful study, said recently that a manufacturing population of over 300,000 might be constantly employed in California if cheap motive power can be had. Costly motive power, derived from coal worth not less than $5 a ton, has been the one great obstacle that has confronted every plan for factories in this State. The only water power to be had is on the turbulent mountain streams, away up in the mountains and rocky, narrow canyons, remote from towns and inaccessible for factory purposes.

The practical demonstration that electricity capable of doing the work of ten, twenty or more thousand horse-power may be transmitted many miles through copper wires, marks the dawn of an industrial era in the State of California, long famous for her gold mines, wines, grains and fruits. A competent authority in the Los Angeles Chamber of Commerce reckons that by electrical power transmission some 280,000 horse-power or more may be developed in the more accessible Sierra Nevada canyons. Experiments have shown that the power may be delivered as cheaply as any in the United States. Senator Androus believes that over 350,000 horse-power may be easily developed in the mountains and transmitted to the adjacent cities and towns, and this, he finds, will be sufficient to propel every street car, elevator and printing press in California, to heat and illuminate the whole Commonwealth and to run all kinds of factories needed in California for another decade.

The electrical-power plants that have already been set up at Pomona, Redlands and Folsom, in California, have shown what electricians and manufacturers may expect. All have exceeded the expectations of their projectors in the cheapness and convenience of electrical transmission. Some $1,400,000 has been invested in such electric plants in this State, but projects are being pushed with all speed for three similar plants—to cost over $4,000,000—that will develop about 18,000 horse-power. The Californians have a reputation of doing nothing by halves, and it seems a mild statement that a dozen millions of dollars will be invested in electrical plants along the canyon streams and in copper wire and machinery in the Golden State in the next five or six years.

A company of capitalists in Pomona saw the possibilities in San Antonio Canyon, sixteen miles north of the town, and with a capital of $250,000 they formed a company, the San Antonio Electric Power Company, for prosecuting the work. The water right was easily and cheaply bought, because the irrigation companies owning the stream and canyon would not lose a drop of water by the operation of the electrical company. The water is merely run through a mammoth iron pipe, dropped upon a water wheel, and then returned clear and undefiled to its original bed to go flowing down into the valley below for the orange and lemon groves and the alfalfa fields. It took a year to complete the work for the electrical company. An artificial waterfall of 387 feet was created, immense water-wheels were set up in a power-house in the canyon, and electrical dynamos with a complement of transformers having the pressure of 10,000 volts were established there. Next a No. 7 copper wire was strung on poles from the power-house to San Bernardino, twenty-eight miles away to the east, and Pomona, sixteen miles down in the valley south of the canyon. At San Bernardino and Pomona sub-stations were erected for the switchboards and the banks of lowering transformers, and then the company was ready to deliver electric power and illumination to patrons in San Bernardino, Ontario and Pomona.

For two years the San Antonio Electric Company has been dealing out in Pomona, Ontario and San Bernardino from 180 to 240 horse-power without an hour of delay or any accident or mishap. The company employs but four men in the electrical service, and it can sell power as cheap as any company in the Union. One man attends to affairs in the power-house in the canyon, but so mechanically and smoothly do things run there month after month that his duties are like those of a lighthouse-keeper. On several occasions the San Antonio Company has joined the circuit so as to make a continuous circuit of eighty-five miles, when it has sent 186 horse-power over the whole circuit. The power has been used to illuminate the towns of Pomona and San Bernardino, and to operate street cars and stationary engines.

In the last few weeks the most important system for long-distance electrical transmission in this country, outside of that of Niagara Falls, has been finished at Folsom, near Sacramento. A grand celebration extending over three days, and participated in by thousands of people from every part of California, marked the completion of the work and the practical demonstration of the possibility of transmitting three separate currents 10,000 volts over the wire lines to Sacramento. The American River furnishes the power at Folsom. A dam was built across the river and a stream of 85,000 cubic feet a minute is run through a tunnel and over turbine wheels, where power is created for the mammoth electric dynamos in the power-house near at hand. The water is used further down the valley for irrigating, and it is enough to cover well 300,000 acres of land.

In the dynamo room are four three-phase alternating-current generators, each capable of developing 1,000 horse-power, the shafts of which are coupled direct to the shafts of the four water-wheels. These dynamos are the largest in the world, with the exception of those at Niagara Falls, and weigh about forty tons each. The electric current developed by these enormous machines is passed through raising transformers, which increase the voltage to 10,000 volts, at which pressure it passes through the wires of the transmission lines. There is a double-pole line over the twenty-four miles from Folsom to Sacramento, thereby guarding against any delay for repairs or renewals, one line always being in reserve. It is estimated that four-fifths, or 80 per cent., of the electric power developed is transmitted to Sacramento along the bare copper wires strung on poles. The 20 per cent. of loss could be much reduced, if necessary, by using heavier wires, but with the enormous water-power at Folsom it is not desirable to increase the copper wire beyond a certain point. The electrical energy from Folsom is used to propel street cars in Sacramento, to illuminate and heat the city, to run the machinery and presses in the State printing office and to operate stationary engines throughout the city. Two factories for the manufacturing of boots and shoes are soon to be established in Sacramento. A company of Boston and New York capitalists has been at work in Los Angeles and Kern Counties for six months in devising plans for developing electric power in the Kern River, among the chain of mountains west of Bakersfield in the San Joaquin Valley. The company has spent over $15,000 in getting water rights, and it proposes to develop some 12,000 horse-power in the Kern River, after the engineering methods employed in the San Antonio Canyon, and to transmit the same through copper wires, a distance of 110 miles from Los Angeles City. It will require four or five years and several millions of dollars to finish the undertaking. The company has engineers now at work in the mountains making surveys for a series of dams to be built across the river. It is reckoned that the motive power the company thinks it can bring to Los Angeles will heat and light the whole city, and will furnish sufficient power for half a dozen large factories, besides propelling every street car and engine in Los Angeles and its suburbs.

Down at San Diego, where one of the most famous of the big irrigation dams of the world, that at Sweetwater, has stood for seven years, it is proposed to get some 3,000 horse-power at the dam and transmit it to San Diego and National City, twenty miles distant. U. S. Grant, Jr., and Jesse Grant, sons of Gen. U. S. Grant, are at the head of a company which has the plan in view. Electrical engineers have reported that nowhere can horse-power be developed and transmitted cheaper than there in San Diego county. There are other great water powers in the San Diego mountains and canyons, and it is believed the Atchison, Topeka and Santa Fé Railroad Company is interested in having its civil engineers search there for a new motive power for its locomotives on the Southern California division. At this writing a committee of three Californians is in London seeking to interest capital in the field of electrical power development in Southern California for railroad locomotive and cotton and woolen factory uses.

In that branch of the Sierra Nevada back of Fresno and Stockton, in the upper part of the great San Joaquin Valley, a company of Chicago and San Francisco capitalists has had electrical and hydraulic engineers at work ascertaining the amount of power that may be created there, and the best means of conveying it from the mountain streams and waterfalls to use in Stockton, Fresno, and, possibly San Francisco. Enough work has been done to show that some $3,500,000 will be necessary for the work, and that at least 40,000 horse-power may be sent in an electric current from the transformers over several copper wires through the San Joaquin Valley. The distance this power will be carried is about 150 miles in all, something that would not have been seriously considered among electricians several years ago.

[1] Abstract from correspondence in the N. Y. "Evening Post."

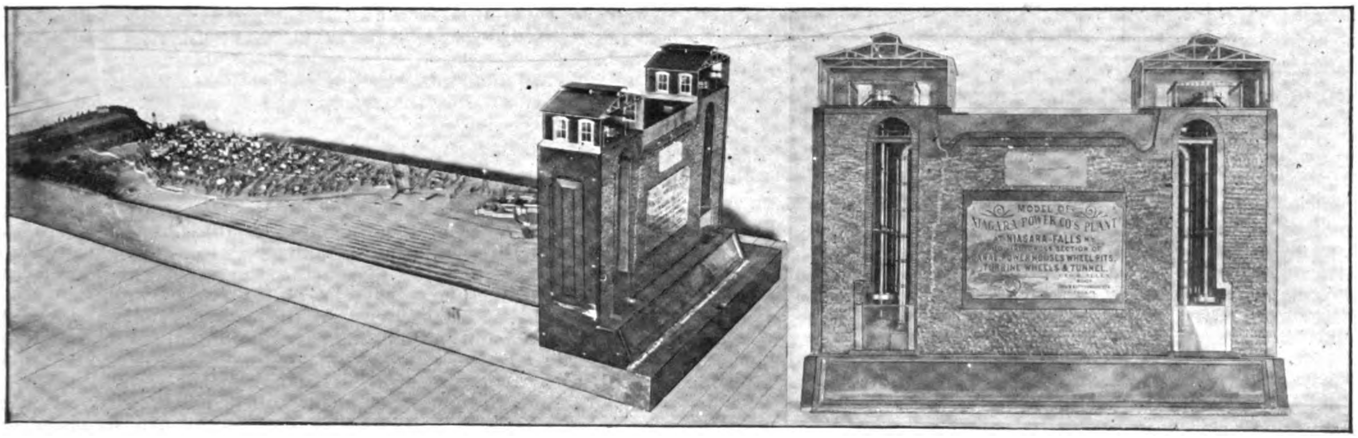
POWER FROM NIAGARA TO NEW YORK.

BY ORRIN E. DUNLAP.

IN connection with the ingenious and feasible plan of operating, at the National Electrical Exposition in New York City by Niagara energy, the interesting little model of the Niagara Power Company's plant, whose great original will itself furnish the current, I believe that a few details as to the model now being set up in New York will be of interest.

Fig. 2 gives a front view of the model, showing the great electric power-generating plant of the Niagara Falls Power Company in miniature. In Fig. 1 is seen a bird's-eye view of the upper Niagara River from the big power house to the gorge, the city of Niagara Falls, the Niagara gorge and a bit of Canada on the distant side. So well planned is this model that it shows the city of Niagara Falls and surrounding locality from a point just beyond the line of the power tunnel on the north to the center of Goat Island on the south, and from a point beyond the Clifton House, Canada side, on the west to a point beyond the big tunnel canal on the east. The model is 12 feet long by 3 feet 6 inches wide. The height of the model when on exhibition is about six feet, but one-half of this is in a fine glass-case, which protects it from meddlesome hands and dust.

In placing the model on exhibition those in charge will take great care to see that the points of the compass are faithfully maintained, and thus those who study its detail and plan will have a correct understanding of the location of the river, the power plant and the city of Niagara Falls.



FIGS. 1 AND 2.—WORKING MODEL OF THE PLANT OF THE NIAGARA POWER CO., AT THE NATIONAL ELECTRICAL EXPOSITION.

By glancing at Fig. 1 the reader will see that at the east end of the model a little wooden case rises above the main surface of the model, and, standing in front of it, one learns by a statement on a metal plate that they are looking at a model of the Niagara Power Company's plant at Niagara Falls, N. Y., and such it is. The power houses, wheel pits, cross-section of the canal, turbine wheels and the tunnel are all before you. In this is found the actuating thought that led to the construction of this truly wonderful piece of work. Day after day many visitors at the Falls make eager inquiries as to the workings of the tunnel and its object. Some find this a difficult matter to explain, but here it is all plain. In this model is shown what can be seen in no other way, for it would be utterly impossible to take all the visitors down into the deep wheel pit to show them the workings of the turbines. When power is applied water will flow down the penstocks upon the turbines, which will set in motion the turbine shaft, to the dynamos that will generate the power in the original installation. There is a sectional view of all this, showing the turbines, the penstocks and shafts. On the cut is shown the dynamos with a small flight of stairs leading to the top of them. As the water passes from the turbines it enters a drift or small tunnel leading to the main tunnel and is carried through it to the gorge below. Standing on the north side of the model a sectional view of the entire length of the tunnel and the water passing through it is obtained. Air bubbles are pumped into the water so as to make it more perceptible to the sight.

To one standing one the west, or Canadian, side of the model the portal of the tunnel, the Niagara gorge, the American fall and a portion of the lower river are visible. True to nature, the little steamer, "Maid of the Mist," is seen near the dock on the American side. The arrangement of the American fall and the center fall, the little fall between Luna Island and Goat Island, is most perfect. The effect is created by a porcelain plate tinted and burned in.

Six electric lights located in various parts of the city and three lights in the Cataract House shine forth and add to the scene. While the model was at the Falls they were operated by a storage battery concealed beneath, but in New York Niagara power, live and stored, it is expected will be called into service.

One thing that all will be impressed with is the beauty of the river as it is represented. The upper river is shown from the Falls to a point above where the tunnel canal taps the river. All the islands and bridges are shown. The river-bed, on the part above the rapids, is of glass. Midway down the south side of the model the glass ends. To this point the water flows underneath the glass when it runs out and flows over a bed made of lead, representing rock. Where the rapids of the upper river are the lead is wavy, and the rapids are shown distinctly. As the water passes over the precipice it drops behind rocks at the bottom and passes underneath the glass river-bed of the gorge.

In this connection it is interesting to note that while the model was made by George R. Allen, of Philadelphia, that part of it which has to do with the power development was made under the supervision of Coleman Sellers, Chairman of the Board of Engineers of the Cataract Construction Company, thus assuring perfect accuracy in the portrayal of this truly wonderful plant.

Quite naturally, in such a work, the buildings of the city hold the eye, and among those that attract most attention are the Cataract House, the center power station of the Niagara Falls Power Company, the many buildings that compose the plant of the Niagara Falls Paper Company, and the various churches in that portion of the city shown. All these buildings are made of wood, excepting the famous old Cataract House, which is of cardboard. As a whole, the model is destined to do much to give visitors a clear idea of what has been done to develop Niagara power.

In the construction of the model the scale used was one of about 100 feet to an inch and a half. Thus a comparison of this fact with the dimensions above given will give one a very fair idea of the model. All the streets and buildings shown are perfect in form and direction. To one acquainted with the city of Niagara Falls, it affords pleasure to pick out well-known places. The total number of buildings shown is 197, while the number of trees which grace the streets of the city in the model is 1,150. Every one of these trees Mr. Allen, the model-maker, tried to locate with precision.

"BUSTED" BOILERS IN AN ARGENTINE PLANT.

A telegram from Santa Fé states that two large boilers in the electric light factory exploded on Sunday night. The roof was blown off and the boilers were carried to a distance of two squares, destroying trees and injuring houses on their way. Three persons were injured and one of them died. The factory cost $120,000 gold.—Buenos Ayres "Herald," Jan. 21.

THACKARA & CO. have had their big gas and electric fixture establishment burned out.

Electric Lighting.

THE NEW THREE-PHASE ELECTRIC LIGHTING SYSTEM AT SALT LAKE CITY.

In August, 1895, it became necessary to make immediate provision to increase the dynamo capacity in Salt Lake City, in order to meet the demand for lighting. A contract had been made with the Big Cottonwood Power Company for the supply of power, but there was no prospect of getting this power until the spring of 1896. By this contract the Big Cottonwood Power Company have undertaken to develop a water power in the Cottonwood Canyon and transmit electricity over a distance of 14 miles into Salt Lake City, and there to sell the power to the Salt Lake & Ogden Gas & Electric Light Co. This undertaking was fully described in "The Electrical Engineer" of Sept. 12, 1895. The Big Cottonwood Power Company will install a three-phase alternating system with a 10,000-volt transmission, stepping down at the distributing station in Salt Lake City to 2,000 volts. With these plans in view it was deemed advisable to put in three-phase dynamos at the Salt Lake electric light plant of sufficient capacity to supply the commercial center with incandescent lights, and machinery for this purpose was purchased from the General Electric Company and erected last November.

Generators.—The generating machinery consists of two 150

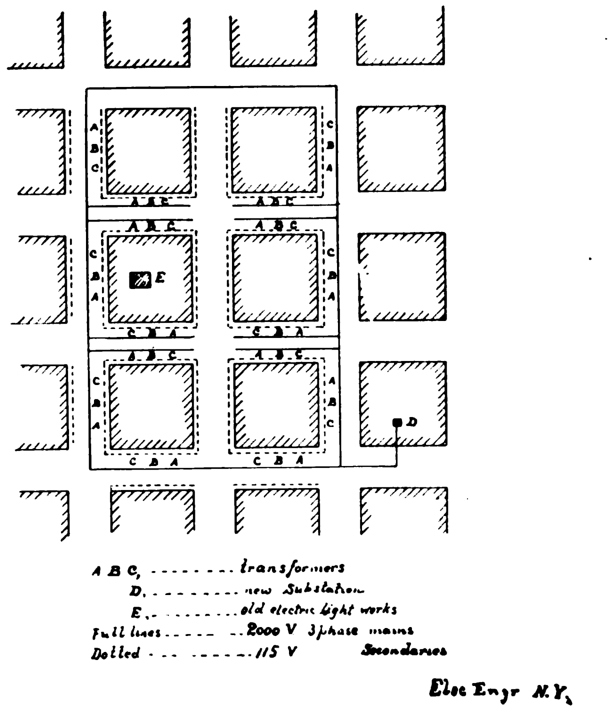


Fig. 1.—Plan of Primary and Secondary Mains in Commercial District.

kilowatt and one 50 kilowatt three-phase alternators. One of the large dynamos is belted to a countershaft with other dynamos and driven by a 600-horse-power Corliss engine, which runs at 100 revolutions per minute. The second is driven off the flywheel of a 250-horse-power cross-compound Armington & Sims engine, running at 230 revolutions. The third dynamo is used for the day load, and is driven off a 150-horse-power cross-compound Armington & Sims engine, together with two Edison dynamos used to supply power.

All the dynamos are designed for 60 cycles. They are compound wound and have iron-clad armatures of the latest type. The 150-kilowatt dynamos are wound for an output of 2,300 volts and 37 amperes at a speed of 600 revolutions; the 50-kilowatt dynamo is wound for an output of 2,300 volts and 13 amperes, at a speed of 900 revolutions. The manufacturers guarantee a commercial efficiency of 94 per cent. at full load on the large dynamos and a temperature not to exceed 70 degrees Fahrenheit above the temperature of the surrounding atmosphere, after a continuous run at full load for 10 hours. There has been no opportunity of testing the dynamos for efficiency at present, but they come well within the temperature guaranteed.

Switchboard.—The switchboard consists of five slabs of pink Tennessee marble, 90 inches high by 30 inches wide. Three of the panels contain switches for each of the three dynamos. One panel is for the measuring instruments, and the fifth panel is for the circuit switches and voltmeter. The dynamo

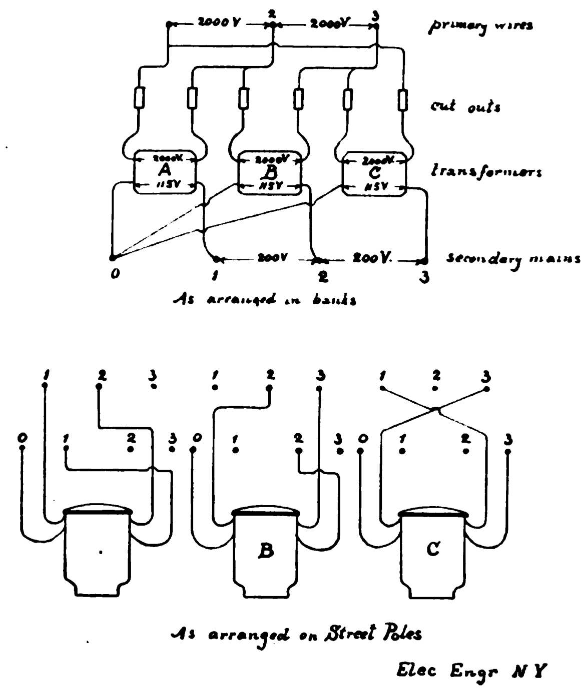

Fig. 1.—Transformer Connections, 3-Phase System.

panel is fitted with a Carpenter enamel rheostat for regulating the exciting current; one exciter double-pole switch; one three-pole main switch; one equalizer switch, for parallel running; one ammeter for measuring the main current on one leg of the three-phase system, and three high-tension fuses and a synchronizing switch. At the back of the board are the three high-tension mains' bus-bars, the equalizer bus-bars for connecting all the compound windings together, and three lightning arresters of the T.-H. magnetic blow-out type, with an additional protection of a flat coil of a few turns of large wire between the arrester and dynamo. Each dynamo has one transformer, which is so connected to a bus-bar that, by throwing a small switch, it can be used for lighting a pilot lamp or be put in series with the other transformers for synchronizing.

The effective current, as measured at full load on one wire of the dynamo, is 37 amperes upon the larger and 13 amperes upon the small dynamo. The total effective current on the three wires is about 1.73 times that on one wire. This being the ratio between the ordinates of one sine curve and the added ordinates of three sine curves at phase angles of 120 degrees. On the instrument panel are three main amperemeters for registering the whole current sent out

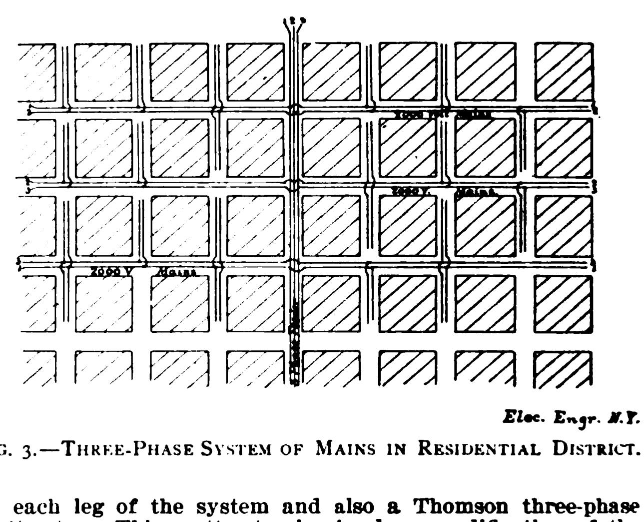

Fig. 3.—Three-Phase System of Mains in Residential District.

on each leg of the system and also a Thomson three-phase wattmeter. This wattmeter is simply a modification of the ordinary Thomson meter, and consists of three separate

meters, the armatures of which are all on the same spindle. On the fifth panel are arranged four three-pole circuit switches, four sets of circuit fuses and a Thomson-Houston voltmeter, arranged with a switch for connecting to any dynamo or any circuit. In addition to these instruments a Bristol recording voltmeter is fixed in the station. The whole board is protected by a wooden canopy, presents a very handsome appearance and is extremely simple to manipulate.

The compound commutators of the dynamos run absolutely sparkless, and there is no trouble at all in synchronizing. It may here be mentioned that the self-induction in the armatures of these dynamos is such that it is impossible to do any damage by a short circuit. Shortly after starting, a short circuit occurred on the main lines, while the small dynamo was running; the result was that the potential at the dynamo dropped off just as if the exciter switch had been suddenly opened, and, furthermore, the dynamo would not give any potential at all when running upon the short circuit. These dynamos, however, will carry 25 per cent. above their rated capacity without any loss of pressure.

The Distributing System.—The distributing system consists of a three-wire high-tension network and a four-wire network of secondary mains. The accompanying plan (Fig. 1) shows how these mains are distributed over the business district. The transformers are placed upon the poles which carry the wires, and the connections are made as shown in the diagram, Fig. 2.

In carrying out a system like this it is, of course, important that the transformers should be fixed quickly without any fear of getting the connections wrong. In order that the linemen may not be able to make any mistake in this, the wires on the poles are numbered, as shown, and the transformers are also lettered. The diagram also shows the position in which the transformers are placed in the streets, and the arrangement is such that in case of fire it would be very easy to cut off one portion of the district without interfering with the rest of the lighting.

In order to save the loss in transformers during the hours of light load, arrangements are being made for cutting out a certain number of the transformers during the daytime, leaving the rest to supply the secondary mains. The transformers are wound for a ratio of 18 to 1, and it will be noticed that the secondary mains consist of a neutral wire and three others. By this means it is possible to get 115 volts between the neutral and any of the three other wires for incandescent lighting, and 200 between any two of the other wires for motor service.

With the exception of one or two little difficulties inseparably connected with installing such a system as this during the heaviest lighting season in the year, there has been no difficulty whatever, and the dynamos and all other apparatus work perfectly. There is no difficulty in balancing up the three legs of the system, and, in fact, once the transformers and the secondary mains are fixed, it is said to be easier to manipulate than an Edison three-wire system.

As soon as the Cottonwood power station is ready for work the preparation will be commenced for connecting the residence district on the three-phase system. At present these districts are supplied on the ordinary 1,000 volt single-phase system. The diagram, Fig. 3, shows how the connections will be made for the three-phase.

The arrangement of the streets in Salt Lake City are convenient for carrying out the necessary changes. The streets run north and south and east and west. The existing 1,000 volt mains run east and west. The three-phase feeder, as shown, will be brought up one of the streets running north and south through the center of the residence district, and each of the streets will be attached to this feeder, as shown in the diagram; thus, where there are three streets, each one of the streets will form one leg of the three-phase system, and the three legs will be balanced by throwing the side streets on to whichever leg requires strengthening or weakening, as the case may be. All the transformers at present installed in stores are wound for 1,000 volt primaries and 52 volt secondaries. Some of the stepdown transformers, supplied by the Big Cottonwood Power Company can be connected for 1,000 volts, and it is proposed to connect up the three-phase feeder to the distributing station, as shown in the diagram, at a pressure of 1,000 volts. The existing transformers would not be very efficient at 60 cycles per second, but as quickly as possible the old type transformers will be transferred to Ogden, while new type transformers will be fixed in the residence circuits, and then as soon as sufficient new type transformers are fixed the voltage will be raised to 2,000 and the house lamps changed from 52 to 104.

This is an outline of the system proposed to be pursued in changing over the residence district from the existing system to the new three-phase system. It will necessarily take some time to carry out this work, but there are portions which can very easily be connected up, while it will take several months to prepare other portions of the town.

In a great many parts of the residence district the houses are so close together that it is very easy to fix one or two transformers to supply ten houses. These transformers will be fixed on the street poles and a short length of secondary mains will be run, from which the houses will be supplied. At these places it is proposed to place two transformers, one, say, for 100 lights and another for about 20, with an automatic switch to cut out the larger transformer, when the number of lights does not exceed the load of the smaller, and so save the loss of power at light load.

From the fact that the installation presents so many points of new and improved central station practice, its operation will be watched by electric light and power men throughout the country with keen interest. The active conduct of this important undertaking has devolved on Mr. R. F. Hayward, the well-known general manager of the company, who has carried it to its present successful stage with characteristic energy and ability.

DIFFUSION AND OPALESCENCE WITH ROENTGEN RAYS.

Elihu Thomson

So far as the writer is aware the phenomena presently to be described have not hitherto been alluded to by writers or experimenters on Röntgen rays. They are the phenomena of diffusion of such rays by certain classes of substances in such a way that such substances must come to be regarded as opalescent, or to act like opal glass in ordinary light, or like milky liquids, a diffusion of incident rays taking place from the interior and exterior of the mass.

Some substances are found to behave with Röntgen rays in the way that compacted snow or translucent ice acts in diffusing light. Let a fairly large metal screen, such as a brass or iron plate of 1-16 to ⅛ inch in thickness, be suspended in a vertical plane about a foot or more from a Crookes tube kept in action and emitting rays toward the plate. On the side of the plate opposite to that nearest the Crookes tube there will, of course, be a space in shadow free from Röntgen rays. This statement, though true in the abstract, may not express the whole truth. It may easily happen that an exploration with a fluorescent screen tube or fluoroscope back of the metal plate will show that the rays are not absent there, but appear to come around the edge of the plate. This phenomenon has been alluded to by Mr. Edison recently and used in support of his suggestion that Röntgen rays are simply high pitch sound waves.

But upon close examination it will be found that the rays back of the metal shield are, at least mostly, due to diffusion from surrounding objects; the walls of the room or the floor, or objects in the room receiving the rays and scattering them. Further examination will also disclose the fact that bodies differ greatly in their diffusive power, and that substances such as paraffine, wood, paper, pure rubber, cloth of cotton or wool, the hand of a person, etc., which are comparatively transparent to the rays are also fairly vigorous in diffusing them.

The diffusion is not merely from the surface or irregular reflection. This is shown by the fact that the surface may be smooth or rough and that the rays come even from the back of the object and from portions not exposed directly to the original rays. This indicates a true opalescence like that possessed by opal glass with ordinary light. It will be seen from this that the shadows of opaque objects imbedded in tissue at considerable depths can never be so black or dense as when the objects are merely surrounded by air. Liquids appear to possess the property as well as solids. The diffusion appears to take place in all directions within and outside of the mass of the substance.

If the fluorescent screen tube used have metal sides of some thickness the large metal plate screen mentioned above can be dispensed with. In this case it suffices that the screen tube be turned so as to be directed at right angles to the direction of the rays or be turned away from the Crookes tube so as not to fluoresce. Pieces of various substances may now be placed opposite the end of the screen tube, but in a position to be partially or wholly exposed to the rays. The pieces will become virtually sources of the rays and the rays diffused by them reaching the fluorescent screen will cause it to emit light.

By placing two exactly similar fluorescent screens at opposite

ends of a dark tube and employing a Bunsen photometer screen movable, as usual, between the screens, a comparison of diffusing power of different materials might be made by subjecting the pieces placed near the ends of the photometer tube outside, to equal radiation from the Crookes tube. The same instrument might be employed to measure the relative merits of Crookes tubes as producers of the rays. The same electrical discharges would be passed through both tubes while opposite each end of the "fluorometer." So also the comparative values of different fluorescent screen material could be tested by slight modifications in the use of the instrument.

By comparing the density of the shadow of a piece of sheet lead when back of a block of wood or paraffine and close to the fluorescent screen, with that of the same piece when the wood or paraffine is between the screen and the lead the effects of diffusion in the latter case in lighting up the shadow are clearly seen on a fluorescent screen.

Though the experiment has not been tried as yet, the writer thinks that a cloud or mass of fine particles of water from a steam jet would diffuse the Röntgen rays. It is well known that the higher pitch light waves are most readily diffused and absorbed by fog, and if Röntgen waves be very high pitch waves similar to light waves this diffusibility need not surprise us, the new rays to be in a sense detectors of molecular turbidity. Whether true gases have the power of diffusing the rays is not known, but the diffusive power, if it exists at all, will be small and difficult to detect.

Metal plates gave apparently little diffusive effect, appearing to reflect feebly at angles equal to the incidence angles. The phenomena of reflection from surfaces have been investigated very recently by Mr. Tesla, and a number of values obtained for the relative reflecting powers of metals, etc. The diffusive action herein noted is different altogether from reflection, and is obtained at all angles from the surfaces and from the interior of the materials upon which the original rays fall.

Note.—The term opalescence is here used to mean milkiness, and not a play of colors, which the term is often used to signify.

KINEMATICS OF THE ROENTGEN RAY.

H. M. Stine

THROUGHOUT the writer's experiments with the Röntgen rays the shadows observed on a sciagraphic negative have been most carefully studied. From the first the penumbral shadows seemed to indicate, when the experiments were carefully plotted, that a limited circular area of the bulb, opposite the cathode, was the prime source of the ray, a fact which

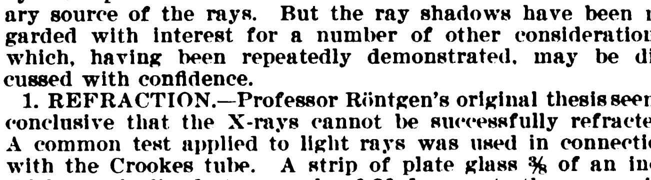

Fig. 1.

I have since fully confirmed. In this article it has been clearly proven that the entire inner surface of the tube bombarded by the repelled molecules is also a more or less weak secondary source of the rays. But the ray shadows have been regarded with interest for a number of other considerations, which, having been repeatedly demonstrated, may be discussed with confidence.

1. REFRACTION.—Professor Röntgen's original thesis seems conclusive that the X-rays cannot be successfully refracted. A common test applied to light rays was used in connection with the Crookes tube. A strip of plate glass ⅜ of an inch thick was inclined at an angle of 30 degrees to the rays, with a metallic rod so placed as to show a broken shadow in case of refraction. It is almost neeedless to state that the shadow was unbroken. Some experimenters have erroneously interpreted penumbral shadows of round rods as indicative of refraction. This error is readily resolved by the method indicated below.

2. REFLECTION.—The attempt was made in a great number of ways to produce reflection from glass and metallic surfaces, singular how the erroneous belief in the reflection of the Rönt- but in all cases the answer was clearly negative. It seems gen ray has taken hold. Experimenters who have announced reflection have seemed to ignore some of the most elementary principles of physics. The maximum reflection stated has been 2.5 per cent. and one places it at 0.4 per cent. The reflection of a wave is molar, and for an angle of 45 degrees should, from the surfaces employed, have been in excess of

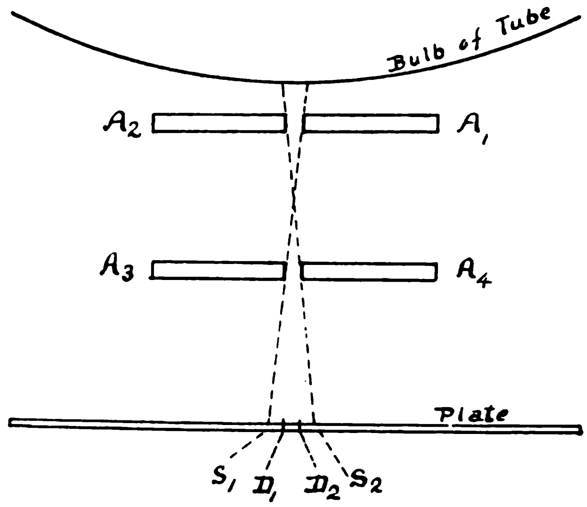

Fig. 2.

50 per cent. The slight reflection would indicate molecular and not molar origin. The nearness of the reflecting plate to the bulbs, taken with the high potential employed, shows that the slight reflection noted was due to the reflecting surface acting as a secondary source of the Röntgen ray. A careful study of Lenard's experiments leaves this in no doubt.

3. DIFFRACTION.—This is naturally one of the first kinematical points to be investigated in the Röntgen experiments. It was noticed that when the opaque object was some distance from the plate, pronounced penumbral shadows resulted. These were of such width as to indicate diffraction. However, when such shadows are plotted back to the tube they are found to be purely penumbral, and not caused by diffraction.

To completely demonstrate this point the experiment illustrated in Fig. 1 was undertaken. Here A_1 to A_4 are brass plates one inch wide and ⅛ inch thick, and of the length of the dry plate employed. They were first fastened together, so as to leave two parallel slots ⅛ of an inch wide. These plates are placed within ⅜ of an inch of the bulb, were one inch apart, and rested 1⅛ inches above the dry plate. The resulting sciagraph is shown in Fig. 2. In the diagram S_1 S_2, the edges of the penumbral shadow are very sharp and distinct. The direction of the rays is indicated, showing that there was absolutely no diffraction. This experiment has been modified in a variety of tests, with always the same result.

All the more interest attaches to this experiment in view of a recent article on "Röntgen Phenomena Due to Sound Waves."[2] In this article the author states that the rays reenter the geometrical shadow of a steel plate. All students of kinematics know that from the relative sizes of the raysource and opaque plate such marked diffraction as is here indicated could not take place.[3] This statement is made not on academic grounds alone, but after carefully going over the experiment as outlined. A steel plate ⅛ of an inch thick was employed, and the calcium tungstate fluoroscope used as a detector. No diffraction could be detected. The shadow was sharp or more less penumbral, according to the relative position of the plate and bulb.

Another curious result has erroneously been interpreted as due to diffraction on refraction, a phenomenon which may be called "undercutting of the shadow." If the opaque objects are a little separated from the dry plate and placed so as to be at an angle and nearly in contact the line of shadow will be broken and creep out toward the abutting object. The explanation of this is simple, if the source-area of the ray is borne in mind. It is due to a shielding from the rays on the part of the abutting object.

4. INTERFERENCE.—Evidences of apparent interference are as common as those of diffraction. Certain dark lines have been in frequent evidence, and for a time were perplexing. These are shown dimly in Fig. 1, though they are very distinct in the negative; they are also designated by D_1 and D_2, Fig. 2.

[1] Electrical Engineer, April 8, p. 357.
[2] Electrical Engineer, April 8, p. 353.
[3] Daniell's "Physics," pp. 114, 115 and 136. [4] Idem, pp. 136, 137.

They may be explained by reference to the ray-source. They are due to the rays in the perpendicular planes in the edges of strips A_1 to A_4.

As would be expected, the lines are darker immediately under the bulbs. By plotting out the entire ray distribution it will be seen that such lines mark out areas where the rays are thickest. These lines are always to be seen defining the boundaries of plates of metal or glass placed directly under the ray-source. The edges of the brass strips being rough were not suitable for reflection, nor could such lines be due to reflection, since they do not lie in any reflected plane. The experiment in Fig. 2 was repeated with ordinary light. Here the flat side of a gas flame replaced the bulb of the Crookes tube and a piece of white paper the dry plate. The dark lines were now lines of brightest illumination. Now was this due to reflection, for reasons just stated? Neither can such lines be explained by interference, for it is to be noted that they are parallel throughout the entire length. Were they due to interference they would be hyperbolic lines diverging from their center.

Some observations on the theory of the X-rays may be permissible. In the article before alluded to the apparent diffraction was taken to indicate that these waves may resemble sound waves. This theory is by no means here presented for the first time. It is suggested by two additional facts. Since we know the source of the ray to be the bombarded walls of the bulb this might be regarded in the light of a vibrating disc. In such cases the vibration must be longitudinal rather than transverse.

The errors in the original deduction are obvious. Sound waves are always molar in origin; ether waves, molecular or atomic. None but molar waves in a medium like the air could so flow around an opaque plate. Sound waves would do this, but can sound waves produce chemical or fluorescent effects?

Further, we now know that the Röntgen rays pass more readily through a vacuum than the air in which they seem to be absorbed, probably by charging the air molecules. Neither of such properties belongs to sound waves.

Much as the older and academic school of physics dislikes to acknowledge it, the evidence in favor of the longitudinal nature of the Röntgen rays is so increasingly strong that it seems wellnigh impossible to explain it away. One of the last resorts of the transverse theory is to attribute the production of the ray to fluorescence. This in reality is an accidental rather than a necessary accompaniment. How else may the action of aluminum-walled tubes or of the so-called "focusing" tubes be explained?

If the ray be acknowledged as a longitudinal vibration it does not follow, as some assert, that it possesses a close resemblance to gravitation. One observation alone shows this error: A metal plate may shield an object placed behind it from the X-ray, but there is no known method for screening an object against gravity, for this would be in violation of the conservation of energy.

ROENTGEN RAY AIR-WAVE THEORY.

BY EDWARD P. THOMPSON, M. E.

I TRIED an experiment which others may also have performed, as far as I know, and which acts as the basis of an argument against the theory of propagation of X-rays by waves of material particles. In the experiment referred to, a shadow of an uncharged Crookes tube was outlined upon a fluorescent screen by the X-rays from a charged Crookes tube. From the fact that the shadows of the electrodes of the uncharged tube occurred, we have evidence that the X-rays passed through the evacuated space. If only the shadow of the vacuum tube itself had been cast, and not those of the electrodes, then it would be fair to conclude that the vacuum would not transmit the X-rays, while the glass of the vacuum tube did the same, as sound would be communicated from one side of the vacuum tube to the other by the vibrations of the glass in unison with the undulations of the air.

Numerous experiments of a similar nature suggest themselves, and from their very simplicity ought to be conclusive. Permit me to propose the following: Support a small fluorescent screen in the center of a large and highly exhausted bulb, so that it does not touch the glass, and let such a support consist, in part, of a fine thread or a coiled fine wire—to prevent communication of vibrations of the glass walls of the bulb to the screen, if such vibrations exist. In case the screen becomes luminous, it would prove that the X-rays were transmitted through a vacuum—overthrowing the air-wave theory in the first experiment. The residual atmosphere, some will say, acts as the medium for the formation of waves, but there should be a proportional reduction of luminosity when compared with that of a piece of the same screen outside of the vacuum bulb in addition to the very slight reduction due to the glass itself.

INFLUENCE OF TEMPERATURE ON X-RAY EFFECTS.

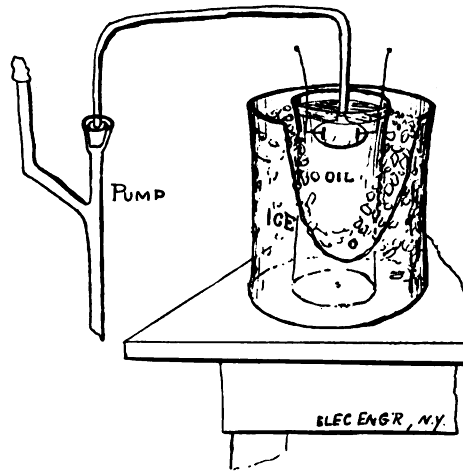
BY

Thomas A. Edison.

FURTHER experiments with the X-ray of Röntgen and Lenard have brought out some important facts which I think will open a wide field for further experiment. It has been noticed by myself, and perhaps many other experimenters, that the relative permeability of different material for the ray was not constant. Different tubes and conditions produced a change in the relative permeability.

It occurred to me that a great change might take place if the bulb was kept at a low temperature. I accordingly placed a tube on the vacuum pump, immersing the tube in a stout battery jar 14 inches high and 8 inches in diameter, the glass being 5-16 inch thick. The jar was filled with heavy paraffin oil. This jar was placed in a large glass jar, 12 x 12, thickness of glass ⅝ inch. This outer jar was filled with water and kept supplied with ice, as shown in the diagram. When the tube was excited the ray which came through the oil to the fluoroscope was of a different character to the ray which comes from the same tube in air. The field of the fluoroscope was bright, but the hand held in front of it gave scarcely any differentiation between the flesh and the bone; one was nearly as transparent to the ray as the other. The hand scarcely altered the brightness of the illumination, and this was true whether the tube was made weak or strong.

A sheet of crucible steel 1-16 of an inch thick, usually cuts off all the ray with tube in air. When held between the bulb



X-RAY TUBE IMMERSED IN AN OIL-ICE BATH.

and fluoroscope, under the new conditions, the steel was quite permeable, giving a fairly strong illumination of the field. A shadow was cast by a piece of steel 2 inches wide by ½ an inch thick. This shadow could be seen through ⅛ of an inch of steel, not only through the oil, but through the oil, water and ⅝ of an inch of glass!

In explanation of these phenomena, we may hazard the view that either the low temperature of the residual glass and gas bulb has increased the length of the waves, or the oil, etc., has absorbed the short waves and permitted the long ones to pass. If the first explanation is correct, a reversal of the condition of the experiment, that is, high temperature conditions, should give shorter waves and sharper shadows; if the second explanation is correct, then all we have to do is to find some liquid or material that well absorbs the long waves and permits the short ones to pass, thus giving sharp shadows.

These experiments show that further investigation should be made in prismatic analysis with liquids, etc.

From continued work in this field I find that bulbs which are spherical at the point where the maximum fluorescence appears are very liable to be pierced, not by the spark, but by a focus of bombardment, resulting in the heating to the melting point of an extremely small part of the glass.

In most cases, if the center of fluorescence is watched, a

non-fluorescent portion will appear; if now the power of the coil is increased there will appear in this non-fluorescent area an extremely fine point which will grow red hot and be forced inward by the atmospheric pressure. I have seen these spots come and perforate the bulb within two seconds. I find that it occurs when the electrodes are perfectly flat, and that it proceeds as a thin concentrated pencil from the exact center coil is increased there will appear in this non-fluorescent area of this concentrated bombardment is increased and the tube can be worked at a higher power before heating. The best remedy is to permit the central ray to strike the glass at a low angle; this greatly increases the area, and prevents the trouble.

X-RAY PHOTOGRAPHS FROM THE WIMSHURST MACHINE.

BY E. W. RICE, JR.

THE literature of Röntgen rays has become so voluminous that it is with great reluctance that I venture to add anything to it. However, in the course of some experiments which I have been conducting during the past few weeks for my own diversion, I have succeeded in making several satisfactory pictures under conditions, which, as far as I know, are quite novel, and which may be interesting to other experimenters.

The source of electricity for these particular experiments was a Wimshurst machine with 16-inch glass plates, giving, under good conditions, with the usual small Leyden jars, about 3½ to 4-inch sparks. The usual method of taking pictures with such a machine is to connect the interior coatings of the two jars, respectively, to the positive and negative conductors of the machine, the terminals of the Crookes tubes being connected between the external coatings of the Leyden jars. In this condition the disruptive discharge of the Leyden jars passes through the Crookes tubes and across the balls upon the terminals of the conductors of the machine, the length of spark being regulated by separating the balls in the usual way. This method has been fully described by Prof. Thomson, and is one which I have followed with excellent results.

In experimenting with a fluoroscopic screen of calcium tungstate, it will be noticed that the fluorescence is intermittent and occurs at the time of the disruptive discharge. Finding this fluorescence unsatisfactory, on account of its intermittent character, I was experimenting with an effort to produce a continuous glow, and after various combinations found that

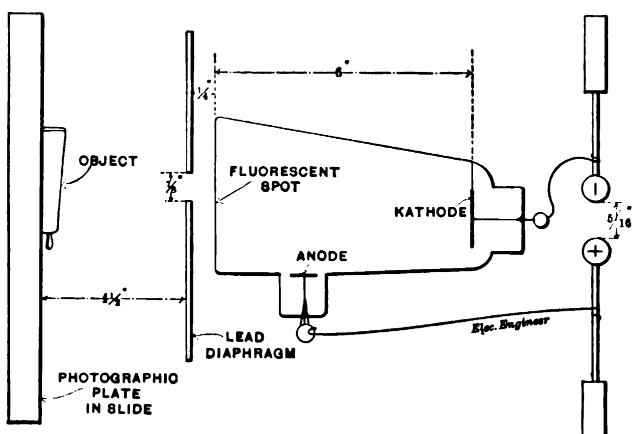


FIG. 1.

with the particular tube that I had then under test a continuous fluorescence could be obtained by connecting the terminals of the Crookes tube directly to the terminals of the Wimshurst machine without the Leyden jars. With this connection the resistance of the vacuum was such that instead of the machine giving the usual continuous violet spark of about two inches in length, the balls had to be brought within a quarter of an inch before sparking would take place.

With the balls removed beyond the sparking point, say three-eighths of an inch or more (the distance being unimportant as long as sparking did not take place), the Crookes tube gave a continuous fluorescence, the fluorescence being produced by the cathode stream, and showing, as usual, a localized spot of considerable brightness at the point upon the glass directly opposite the cathode terminal.

I found that no parts of the tube gave off any rays that could be discovered in the fluoroscope, with the exception of the

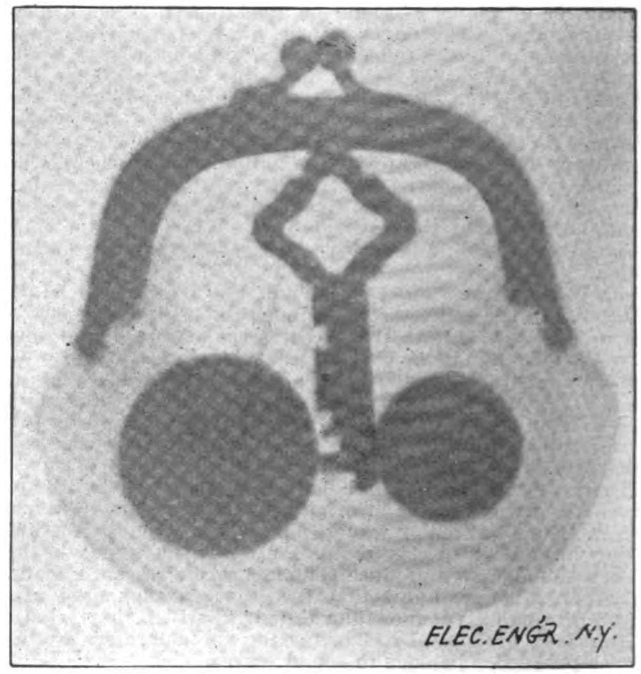

FIG. 2.

bright spot opposite the cathode mentioned above. When the fluoroscope was held close to this pot a bright fluorescence of limited extent was noticed on the screen. Upon removing the screen from four to five inches it became uniformly illuminated with a soft, steady fluorescence, and shadows of the finger and of coins inside of a purse and other well known phenomena were clearly observed. I was greatly surprised at the clearness of the shadows and started immediately to test the photographic powers of the rays, which were evidently being emitted.

The sketch (Fig. 1) shows diagrammatically the conductors of the Wimshurst machine, the general shape and dimensions of the Crookes tube, the disposition of its electrodes and the arrangement and distance of the photographic plate.

I found that good pictures of simple objects could be obtained in twenty to thirty minutes' exposure, and with a lead diaphragm very sharp pictures could be taken in from forty to sixty minutes. The sketch shows a lead diaphragm, with a ⅛-inch aperture, placed about a quarter of an inch below the tube.

Fig. 2 is a silver print of the usual elementary subjects, coins and key within a leather purse, taken under the conditions and with the apparatus above described, using a diaphragm with ⅛-inch opening and an exposure of fifty minutes. During this exposure the terminals of the Wimshurst machine were a little over 5-16 of an inch apart, which was found to be just beyond the sparking limit. In fact, sparking occurred at about a quarter of an inch separation.

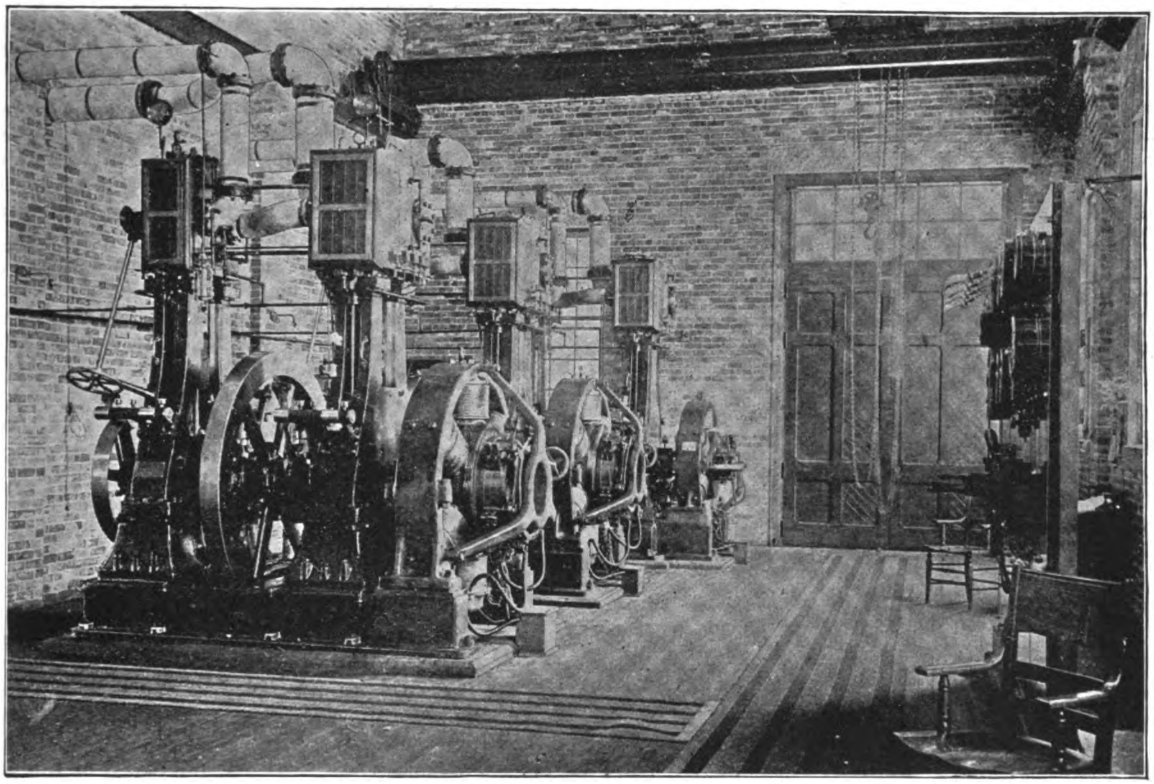
I think that the picture taken shows considerable strength and clearness, and was taken with reasonable rapidity, considering the extremely small potential employed in generating the Röntgen rays. As far as I am aware, the potential was less than has been previously employed with satisfactory results.

I may incidentally remark that I also satisfied myself regarding the matter about which there has been some dispute, namely, the source of the Röntgen ray, as I found that when the fluorescent screen was brought within one inch of the diaphragm referred to, the spot of fluorescent light on the screen was limited; that when moved to about four inches the fluorescence screen, which is 6 x 6 inches, was entirely illuminated. This shows clearly that the rays emanated from the glass, as, if they had emanated from the cathode it would have been necessary to remove the fluorescent screen a much greater distance from the diaphragm before showing a uniform fluorescence. I also could see no indication of fluorescence whatever opposite the anode.

LIGHTING PLANT AT LEADVILLE, COLO.

THE electric lighting plant of the Citizens' Electric Light Company at Leadville, (10,000 feet above sea level), is as thoroughly representative of the latest modern practice in electric lighting as any plant in the East. It is one of the first in this country in which the principle of direct connection has been exclusively adopted and one of the first also operating a very extensive public arc lighting system from incandescent circuits.

Boilers and Engines.—The station occupies a fireproof brick building with iron trussed roof. The boilers are three in number, 60 x 16, horizontal tubulars of 85 horse-power from the works of Brownell Bros., of Dayton, Ohio, and are designed for a working pressure of 140 pounds. Space is left in the boiler room for an additional battery of three boilers. The smokestack is of steel, 4 feet 8 inches in diameter and 90 feet high, set up on four iron columns. Two sets of duplex pumps, each pump of sufficient capacity to operate six boilers, and one National feed water heater complete in boiler-room equipment.



THE NEW THREE-WIRE DIRECT CURRENT, CENTRAL STATION, LEADVILLE, COL.

The three 85 horse-power Lake Erie engines are vertical cross compound, with-cyclinders 7½x13x14 inches. Directly connected to each of the engines is a 50-kilowatt General Electric generator running at 275 revolutions per minute. The third engine has two 25-kilowatt generators of similar type, one on each end of the shaft, running at 300 revolutions. These generators are compound wound, 125-volt multipolar machines with ironclad armatures. During the first two months of the operation of the plant the overload on these dynamos daily ran up to from 25 to 40 per cent., without appreciable heating, while since December, 1895, according to the manager of the station, Mr. G. P. Brown, there has not been a night that all the dynamos have not carried an overload of from 10 to 20 per cent. without experiencing any difficulty.

Switchboard.—The switchboard is of the G. E. central station panel type, 13 feet long by 5 feet high. It is placed well away from the wall to give free access to the back. The conductors are brought to it under the floor and the switches and circuits are so arranged that any dynamo may be operated in conjunction with any other one or more, and on either side of the three-wire system. Two sets of feeders run from the board, and in the event of break down on one set the other may be called into requisition.

Distribution.—The plant is operated on the three-wire system, current being supplied to both arc and incandescent lights and motors. One engine, with the two 25 kilowatt dynamos, is designed to carry the night load from 2 to 5 a. m., the others being cut in as the demand for current requires. By having the generating units thus properly proportioned to the load and capable of being started and stopped at will, great economy of operation is gained, which would not be obtainable by the employment of one or two larger engines. Actual tests on the units installed at this plant showed over 82 per cent., delivered at the dynamo terminals.

The district covered by this system is a little over a mile square, and the lamps at present connected amount to an equivalent of 4,000 of 16 c.-p. There are about 120 arc lamps of the new Thomson type, which have given most excellent satisfaction. The circuits throughout the city are divided into sections, each of which is protected by proper safety devices, so that any trouble occurring on a section will affect that section only.

The main supply circuit consists of an endless circuit, running up the alley west of Harrison avenue, as far as Ninth street, crossing the alley and running down the alley east of Harrison, crossing back again at Chestnut street, making a complete inclosure of Harrison avenue. From this circuit are run the branch circuits supplying consumers east and west. This main circuit is fed at four symmetrical points by the two sets of feeders previously mentioned. The mains consist of three No. 0000 wires. The branches vary in size from No. 4 to No. 0000 wires, with a No. 000 for the neutral. The other feeder consists of five No. 0000 wires.

Since the first month of the operation of this plant the station has been running above its capacity and business has been turned away. The installation of the fourth dynamo relieved the station but temporarily. The company started by supplying current at a flat rate, intending gradually to introduce meters. The majority of consumers now have meters, and the load is gradually falling off, although the income is about the same; this shows the advantages of operating on the meter basis.

The business of the company, as well as the general supervision of the plant, are under the able management of Mr. Geo. P. Brown, with Mr. Richard I. Harrigan as chief electrician. The consulting electricians were Messrs. Shepard and Searing of Denver.

HOOSICK FALLS, N.Y.—The Hoosick Falls Water, Power & Light Company has been formed with a capital stock of $25,000 by G. C. Moses and F. H. Twichell, of Bath, and C. B. Story, F. Riley and G. E. Green, of Hoosick Falls.

CONTENTS.

ACETYLENE AND CALCIC CARBIDE.

GAS interests at the beginning looked upon the electric light as an enemy to be exterminated at all hazards, and by any means, fair or foul. Yet we believe that the gas fraternity will now admit that nothing has so stimulated the industry as their arch enemy, the electric light. This stimulus has shown itself not only in the constantly increasing gas consumption, but in the improvements in the manufacture and methods of utilization of gas as an illuminant. The Welsbach light may be cited as a case in point. Many were the predictions as to its effect on electric lighting, but thus far we have yet to hear of any marked influence of this illuminant on electric lighting. Indeed instances are not wanting where those who abandoned the incandescent lamp for the Welsbach returned to electricity after a brief trial.

We may defer for the present discussing the reasons which prompted this action, to note the situation in regard to the latest rival of the electric light, acetylene. The announcement that a 5 foot gas burner was capable of giving an equivalent of 240 candle-power was well calculated to put all purveyors of light in an expectant, not to say unhappy, mood, but as time wore on the importance of the brilliancy of the light gave way to the question of the cost of producing it. Calcium carbide, the material from which acetylene is made, as is well known, is a result of the electric furnace, produced by the action of the high temperature of the arc on a mixture of coke and lime. When Mr. Willson accidentally discovered that his aluminum furnace was producing carbide of calcium as a by-product, he naturally turned his energy to the conversion of the by-product into the main product of his furnace, and thus it has come about that until lately the main supply of calcium carbide was obtained from Spray, North Carolina. More recently a carbide factory has been erected at Niagara Falls, but as will be shown presently we may well take the Spray works as representing a very fair example of such an establishment.

The cost of acetylene, that is, carbide of calcium, must evidently determine the ultimate success or failure of the illuminant, and the figures quoted for the carbide have varied all the way from $10 to $60 per ton. It was therefore a commendable stroke of enterprise which prompted our contemporary the "Progressive Age" to send a commission to the works at Spray, to investigate and report upon the processes in use there and the cost of producing the carbide in ton lots. This commission, consisting of Messrs. Houston and Kennelly, as electrical experts, and Dr. L. P. Kinnicutt as chemist, have completed their report, which is published in full in our contemporary, and from which we extract a few figures for comment.

According to the report of the commission's investigations "the cost of producing calcium carbide at Spray, by working the furnaces 365 days a year, and 24 hours a day, yielding on an average one ton of 2,000 pounds gross carbide a day, is $32.767 per ton. Of this amount $14.39 is for material. The freight charges on lime and coke are heavy at Spray, and add materially to the cost." We have quoted the commission's report in the above in order to put the matter squarely on record in their own words.

Let us see how this figure is arrived at. In the schedule entitled "Cost of Manufacturing Plant" the item of "Land," upon which the buildings are erected is put down as $100, out of a total of $11,955 for the entire cost value of the plant. This is certainly a low figure and it seems hardly probable that it could be duplicated in other localities combining similar advantages as regards power facilities, such as at Niagara. Next we come to the item of labor, which is given as follows in the report.

Superintendent at $4 per day	$4.00
Three squads of men, 8 hours each	7.00
	$11.00

We consider this figure very low, but pass on to the item

of power. This is given as $5 per horse-power per annum at the turbine. We are certain that nowhere could power be obtained more cheaply, and that that figure would only be reached in a plant employing many thousands of horse-power—if situated at Niagara, for example. If we take into consideration, therefore, the low cost of power, labor, land, etc., at Spray, and especially the fact that the works are run continuously, day and night, including Sundays, it may be fair to assume that the increased cost of material is balanced by the above favorable conditions; so that $32.76 may be considered a fair figure for calcium carbide per ton.

In a table published in the "Progressive Age," on the assumption of $40 as the price of a short ton of calcium carbide, acetylene gives 9,600 candle-hours per $1, or, converting to $32.76 per ton—11,740 candle-hours per $1. By the same table we notice that the Welsbach burner, with gas at $1.65 per 1,000 cubic feet, gives 12,121 candle-hours per $1, thus putting acetylene below the latter in commercial value. This is hardly encouraging for the advocates of acetylene, and if its use be confined even to enriching other illuminating gases, its demonstrated cost must practically make its use prohibitive.

Messrs. Houston and Kennelly supplement their main report by a calculation of the probable cost of the carbide, if the plant were a large one—1,200 horse-power being assumed—with power at $5 per annum, works operating 300 days per year, and coke $2.75 and lime $2.50 per ton, respectively. With these conditions obtaining, they arrive at the figure $20.04. Such a plant would require an investment of $44,700 and would produce only 1,500 tons of carbide, costing $30,062, evidently a small manufacturing output for so large an investment. If to the $20.04 there be added the cost of business administration, and a profit of, say, 15 per cent., this figure would be materially increased. To this must be added the cost to the consumer of the freight charges, which would probably be quite as high, as calcium carbide is bulky for its weight. It may be argued that the acetylene may be compressed and liquefied at the works, but in that case the cost of compression would amount to a respectable percentage of the freight bill of the carbide in bulk.

With these figures before us, which are probably as favorable to the cause of acetylene as they could be fairly made, there would appear to be little to be feared from that source, so far as electric lighting is concerned. But even if the showing were more favorable, the fact that acetylene is a gas, with all the faults, and some added ones, of coal and water gas, must always militate against it as compared with the healthful and cool incandescent and brilliant arc. It would, of course, be useless to deny to acetylene any commercial value whatever, for we believe that it has large and remunerative fields open to it; but as a competitor for general illumination it can hardly yet be said to be reduced to a commercial basis.

THE RELATIVE COST OF ELECTRIC AND STEAM POWER.

It may be considered a bold statement that not one steam user in a hundred knows just what his power is costing, and this relates probably as much to the large as to the small steam user, though the latter, of course, is more apt to be at sea on this important item of cost in manufacturing or current generating purposes. That the assertion above made is fairly accurate must be apparent by the varying figures one sees quoted as coming from steam users, the majority of whom usually fail to take into consideration items which properly belong in the category of steam engine operation. This question, however, is of increasing importance, now that numerous water powers are being transmitted to manufacturing centers, and any light that can be shed on it will aid materially in placing the matter correctly before power users. That the interest in the subject is a live one is shown by several communications we have received asking for an explanation of what is meant by Dr. Charles E. Emery in his note in our issue of April 8, wherein he states that Mr. H. A. Foster in reporting cost of steam power by the horse-power year, instead of the horse-power hour, "not only deceived himself, but many others." Dr. Emery, to whom the inquiry was forwarded, responds that he will explain the matter fully later, but that the principle will be understood by the following illustration: If ordinary 10-hour steam power costs $30 per year, 24-hour steam power for the same number of days in the year would cost $72 per year, and for variable power each average horse-power would cost $72 per year; but if the number of horse-power hours for variable power only equaled those for ten hours at a maximum power, the number of average horse-powers would be only 10-24 times the number of maximum horse-powers, and the yearly cost for the whole power be the same as for the maximum horse-power on a 10-hour basis, or at the rate of $30 per year. The charge for water power must be for maximum horse-power, and therefore must compete with steam power on the same basis. Such charges must therefore be compared with the $30 per horse-power year and not the $72. Mr. Foster only gave the higher prices in the article referred to (Electrical Engineer, June 26, 1895), which it would therefore seem are not applicable, and concluded his presentation by the sentence: "The general result as shown by the above table is that steam power is costing much more than the users, or, in fact, engineers in general, have heretofore estimated." A different result would have been shown if his comparisons, instead of being on a horse-power basis, had been derived from the horse-power hours substantially as above stated.

THE VARIETY OF THE EXPOSITION.

ENOUGH data with regard to the coming National Electrical Exposition in this city have appeared to show that it will possess a variety of attractions going even beyond the plans of those who originally projected it. It will, indeed, be fairly and generously representative of all the electrical arts, for it is hard to think of a branch that will not be included in some interesting form or other.

Although held under the auspices of the National Electric Light Association, the Exposition is very far from being restricted to the field that was covered by the Association when it was founded. As a matter of fact, the Exposition will accentuate, and direct attention to, the remarkable fact that central stations are rapidly undergoing evolution, and that every day they become less and less plants for mere lighting, and more and more reservoirs for the supply of current for a wonderfully wide range of uses, many of which are barely yet known.

Looking, moreover, over the long list of exhibitors, one is struck again with the fact that the "independent" companies are so numerous, so strong and so energetic. It is true that the General Electric-Westinghouse combination will have fine displays, but they will be relatively insignificant, both in scope and quantity and in the resources exhibited, as compared with the multitudinous displays of some 150 concerns all building apparatus or supplies for the open market. In fact, if both of the largest concerns were unrepresented, the show would still remain rounded, complete, and an adequate presentation of everything that a purchaser can need who wishes to enjoy the modern facilities and conveniences of electricity. Both companies will of course have fine and interesting exhibits, but with so many young and keen rivals around them, the truth will appear which we have already urged, viz. that they have no monopoly and cannot secure one, but that their business success must rest upon the merit of their goods. If any manufacturer thinks that either of these great concerns will be satisfied to rest supine under the ægis of a mass of patents and will not try to win by cheapness and superiority, we fear he is likely to be mistaken.

All things considered, both in the scope of its displays and in the stimulus it gives to another period of prosperity in the electrical industries, the Exposition seems destined long to be memorable.

TELEPHONY AND TELEGRAPHY.

ON TELEPHONIC DISTURBANCES CAUSED BY HIGH-VOLTAGE CURRENTS.[1]—II.

BY DR. V. WIETLISBACH.

The telephonic disturbances most difficult to deal with are those considered under III., i. e., those due to induction. The most effectual means of combating this class of disturbance consists in doubling the telephone conductor, the two wires being placed as closely as possible to each other, and the telephone apparatus at each terminal being inserted between them.

A high-voltage line in proximity to the double telephone line will produce in each of the two wires a disturbing current which will flow to the same terminal, where both currents compensate each other; no disturbance will, therefore, be noticeable in the telephone apparatus. When the disturbing cause is not of excessive magnitude, this remedy will give satisfactory results. But when, on the other hand, the value of the disturbing current is several hundred or several thousand times greater than that of the normal telephone current, the remedy must of necessity fail. In that case corresponding precautions are required also in respect of the high-voltage line, i. e., the latter must, like the telephone line, be provided with a metallic return, the two wires being placed in close proximity to each other, and requiring, moreover, a very high degree of insulation. Currents of approximately equal amount will then flow in both the high-voltage wires in opposite directions, and the same will apply to currents which are thereby induced in the telephone line, and which will, therefore, virtually neutralize each other.

Thus, in respect of the difference of induction, a twofold effect is obtained: one between the high-voltage, and another between the low-voltage wires; and it only remains to place the two lines at such a distance apart from each other as will ensure the noise being sufficiently deadened. This distance is obviously governed by the parallel length of the two lines and by the nature of the inducing high-tension current. In order to get rid of the noise altogether the two pairs of wires should, moreover, be placed in a properly-defined reciprocal position. Suppose the wires 1 and 2 to form the high-voltage circuit, and the wires 3 and 4 the low-voltage circuit, and suppose r_{13}, r_{23}, r_{14} to be the distances between them, the equation for reducing the inductive effect to 0 is—

$$r_{13} \times r_{24} = r_{23} \times r_{14}.$$

In practice, however, this result can only be obtained approximately. The complete metallic circuit gives satisfactory results only when the insulation is perfect at all points, and the two component parts are electrically and in every respect perfectly symmetrical. This desideratum is attainable in short telephonic lines, but to permanently maintain this perfect condition in telephone lines extending over hundreds and thousands of kilometres, is a practical and technical impossibility.

This is obvious from the following considerations: When at the terminal of a telephone line of, say, 500 kilometres (312 miles) in total length, a high-voltage current line runs parallel to the telephone line for a few hundred metres, a single point of defective insulation, e. g., the contact with the branch of a tree at the whole terminal, suffices to immediately produce along the whole telephone line a noise so marked as to render telephonic communication absolutely impossible. Nor is this all. When the noise is sufficiently violent it spreads to all the other telephone lines which use the same poles as the disturbed line for part of the total length of the latter.

When, for example, a slight defect occurs in the telephone line from Zurich to Geneva, the noise produced by a high-voltage installation, e. g., the electric tramway in Zurich, spreads not only from Zurich to Geneva, but makes itself more or less felt in all lines which, for part of the distance, use the same poles. Hence the noise is perceptible also at Lausanne, Berne, Fribourg, Neuchatel, Bienne, Chaux-de-Fonds, Basle, and generally throughout the telephonic system of Western Switzerland. Under unfavorable circumstances, i. e., when the noise is particularly violent, it may even, by secondary or tertiary translation, spread from the Zurich and Geneva line to the Berne and Basle line, thence to the Basle and Bienne line, and thence to the Bienne and Chaux-de-Fonds line at the points where Basle-Bienne runs parallel, not to Zurich-Geneva, but only to Berne-Basle, and again, where Bienne-Chaux-de-Fonds runs parallel only to Bienne-Basle.

This phenomenon is one of the most difficult to deal with, and is, as a rule, not sufficiently taken into account. The telephone system of Switzerland now comprises a total wire length of about 60,000 kilometres (37,500 miles)[1], and it is therefore obvious that the task of maintaining so large an aggregation of lines at all points in faultless condition is by no means an easy one. In many cases the only way to obtain a fairly satisfactory result is to bury the specially exposed or affected sections of a telephone line underground; but it is not worth while to incur the trouble and expense which that operation involves, unless a large number of telephone wires can be buried at the same point and at the same time.

A further remedy consists in translators, which correspond to the transformers of high-tension installations, and which connect two sections of a telephone line electrically by electro-magnetic induction, but at the same time prevent the injurious effect of a fault in the line, e. g., leakage to earth, abnormal resistance, etc., being transferred from one section to the other. The effective capacity is, by this means, also lessened. When, e. g., the telephone sections Zurich-Berne and Berne-Geneva are connected by a translator at Berne, any leakage which may take place in Geneva does not affect the Berne-Zurich section. The efficiency of translators does not, however, exceed 90 per cent., and, though they furnish a means of restricting the effect of a telephonic disturbance to a given section of the entire line, they involve, on the other hand, a loss of energy.

Other remedies, such as a differential arrangement of wires, Muller's method of running the wires, etc., can only be regarded as of minor importance; for though they may render valuable service in special cases, they are not suitable for general application.

The noise produced in the telephone by a disturbance varies, of course, greatly in degree, and depends essentially on the amount of the high-voltage current and on the parallel length of the high and low-voltage lines. Where the high-voltage line is well insulated from earth, and the wires constituting the high-voltage circuit run parallel to each other, it is, in the majority of cases, and particularly in conjunction with the metallic return, also of the telephone line, practicable to place the two lines in juxtaposition for short distances not exceeding a few hundred metres, even in the same street. But when the parallel length extends over one kilometre or more, the noise may be distinctly observed, even though the two lines be as much as 100 metres or more apart. It would seem that the configuration of the ground, too, may exert a certain influence. When the high-voltage line, e. g., that of an alternating current installation, is insufficiently insulated, or, what is worse, is connected to earth, a single crossing of the telephone line, even though it be at right angles, suffices to produce in the telephone a humming disturbance of a very marked character.

Conspicuous among high-voltage installations connected to earth are the majority of electric tramways. As a rule, these tramways are worked with continuous current, which is, however, by the motion of the motor cars converted into a pulsating one. And since the current is conveyed only by one wire, and the compensating effect of the metallic return is wanting, the telephonic disturbance is much greater in proportion. In Switzerland there is only one electric tramway, which, instead of using earth, i. e., the rails as return, has a complete metallic circuit constituted by two overhead wires, to-wit, the Vevey Montreux-Chillon tramway. The effect of the working of this tramway upon the telephone line running along the same road is noticeable where that telephone line is only single with earth return, but the slight noise disappears almost entirely where the same telephone line has two wires.

All the other electric tramways so far constructed in Switzerland use only one conductor, which is suspended above the rails, and from which the continuous current is conveyed either by trolley wheel or by slide contact to the motors of the cars, whence it passes through the car frame and wheels to the rails, and through the latter is intended to flow back to the generator. The rails are generally imbedded in the roadway, and more especially in wet weather insulation is either defective or is wanting altogether, the insulating resistance being only 15 to 20 ohms per kilometre. Hence, a more or less large proportion of the current spreads through earth or straggles back to the generator by water and gas pipes, or by telephone wires, the telephone lines connected to earth being thereby subjected to the intrusion of the high-voltage tramway current. In order to obviate this, the rails should be insulated from earth as well as possible, and that might be accomplished by imbedding them in cement or asphaltum. Experience tends apparently to show that where the permanent way is imbedded in wood pavement, the loss of current is greatly mitigated.

[1] This is equal to 20 kilometers (12.5 miles) per 1,000 inhabitants.—TRANSLATOR.

Electric Transportation.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—IX.

BY

Wm. Baxter, Jr.

If the power of a locomotive is limited, then the horizontal effort it can develop is inversely proportioned to the velocity. Calling the power P and the horizontal effort F we would have

$$F = \frac{P}{V}.$$

Calling the total resistance of the train R we would also have

$$F = R.$$

Now R is the sum of two resistances, the tractional resistance and the atmospheric resistance. Calling these R_1 and R_2, respectively, we would have

$$R = R_1 + R_2 = F = \frac{P}{V}.$$

The atmospheric resistance R_2 is a quantity very difficult to ascertain, but for the purpose of a comparative estimate it matters little whether the value assumed is rigorously correct or not. According to the experiments of Mr. O. T. Crosby, on atmospheric resistance, the variation is proportional to the velocity for speeds within practical limits.

This is not in accordance with the theory that has been accepted heretofore, which is, that resistance of gases and liquids increases as the square of the velocity. But Mr. Crosby's experiments were quite extensive and carefully made, and furthermore, agree more closely with observed facts than the older theory. Therefore it would seem that calculations based on his results would be more accurate. Proceeding on this basis we can assume that the atmospheric resistance to a train is equal to the resistance on an area normal to the line of motion. We would then have $R_2 = AVC$, where C represents the pressure at unit velocity and A the total area. We could deduce C from the figures given by Mr. Crosby and others, but I believe more accurate results can be obtained by taking them from the actual performance of the Empire State Express in the following manner:

Take the power developed at, say, 70.5 miles, that is, 1,059 horse-power = 34,947,000 foot-pounds per minute, and this divided by 70.5 x 88 (88 being the number of feet per minute for a speed of one mile per hour), gives 5,649 as the horizontal effort, friction not being deducted. According to the best authorities, the friction of a locomotive ranges from 5 to 10 per cent. Ten is undoubtedly too high, but on the other hand five looks very low. If we take it at 6 per cent. we would have

$$5{,}649 \times .94 = 5{,}310 = F = \frac{P}{V}.$$

The weight of the train from which the data in Table 10 were obtained was 270 tons. The tractional resistance of such trains on good steel rails is conceded to be about six pounds per ton, and on this basis the value of $R^1 = 270 \text{ x } 06 = 1{,}620$ pounds; and R_2 would be equal to

$$\frac{5310 - 1620}{70.5} V = 52.34 V.$$

From the foregoing we obtain

$$V = \frac{P}{F} = \frac{P}{R_1 + R_2} \quad \text{.......... ....(1)}$$

$$R_1 = \frac{P}{V} - R_2 \quad \text{.......... .... (2)}$$

$$R_2 = \frac{P}{V} - R_1 \quad \text{.... .... (3)}$$

$\frac{R_1}{6}$ = weight in tons that the locomotive can draw.

From these equations the results given in Table 11 have been obtained. As will be noticed the figures are given for a locomotive capacity of 1,059 and also for 1,250 horse-power.

From the data in Table 10 it is fair to assume that the maximum capacity of the locomotive from which the figures were obtained is about 1,060 horse-power, and this amount of power, as shown in Table 11, would draw a train of about the weight of the Empire Express at the rate of about seventy miles per hour on a level track. If a locomotive can be built that will give a continuous output of 1,250 horse-power, it would draw the same train at a speed of 80 miles per hour. These figures may be disputed in view of the fact that speeds of over one hundred miles per hour have been recorded; but it must be remembered that the results were obtained on short spurts of two or three minutes' duration, which is a very different thing from a sustained run.

It is possible by starting with a very bright fire and an extra high pressure of steam to develop an amount of energy

TABLE 11.

Capacity of Steam Locomotives at Different Speeds.

considerably beyond the actual capacity, and thus for a short time obtain a very high speed, but the extraordinary strain on the boiler under such conditions would soon reduce the pressure and the spurt would come to an end. I believe that it is perfectly safe to say that the most powerful locomotives in use could not maintain a speed greater than 70 miles per hour on a level track with a train weighing, including engine, 270 tons.

Now let us see what electric motors could do. As already stated, the maximum torque of a motor can be obtained at any speed. It must not be understood by this that any given motor will pull just as much at one velocity as at another, for such is not the case. If it is wound to give the maximum torque at 60 miles per hour its pulling capacity will drop very rapidly as soon as this speed is exceeded; but if the motor is wound for any given speed it will give its maximum torque at that speed. Table 12 shows the loads that electric motors would draw at different speeds, and it is based on the assumption that the motors are wound to give the maximum torque at each speed given in the table.

It has already been shown that the energy output of an electric motor is not limited, practically, because it has the entire power station behind it; therefore the horizontal effect, instead of being equal to power, divided by velocity, is equal to a constant, and the numerical value of this constant is only limited by considerations of economy. In the table the horizontal effort has been taken at 6,222 pounds and also at 10,000 pounds. The first figure has been taken, because it is the same as that of the locomotive in Table 11 for 60 miles per hour, and thus the figures for succeeding speeds show us at a glance the advantages of electric motors over steam. The other figure, that is, 10,000, has been taken to show what speeds are possible with electric motors. As to the possibility

of obtaining a horizontal effort as high as this figure there is no room for doubt. It is already a matter of record that the electric locomotive in the Belt line tunnel in Baltimore can develop a drawbar pull far beyond this amount.

The figures in this table show that motors giving a horizontal effort of 6,222 pounds could draw cars weighing 140 tons at a speed of 100 miles per hour. And this is a weight only thirty tons less than the Empire State Express, exclusive

of locomotive. We also see that with a horizontal effort of 10,000 pounds a train weighing 358 tons could be drawn at a speed of 150 miles per hour. These results look startling, but if we investigate further we will find that 10,000 pounds at 150 miles per hour equals 4,000 horse power.

It is not at all certain that even 4,000 horse-power would draw a train of such weight at a speed of 150 miles per hour. This estimate is based on the supposition that the atmospheric resistance increases directly with the velocity, and although the experiments of Mr. Crosby go very far toward demonstrating that this is the true relation there is still a great deal of room for doubt.

But outside of the question of power, there are other things that have to be taken into consideration. The wear and tear at such a velocity would be largely increased, not only on the rolling stock, but also on the roadway, and the increased expense in this direction might be enough to render such speed prohibitive.

It may be of interest, therefore, to know to what extent speed can be increased, without increasing the cost of coal consumed per hour. As this increase would not be so very great we can assume that its effect on wear of road and rolling stock would not be serious.

As has already been shown, the cost of coal per horse-power delivered on the track is about half as much for electricity as for steam; therefore, twice the power can be used at the same expense. We will then assume that electric motors of 2,100 horse-power would cost the same to operate (so far as cost of coal is concerned)) as the locomotives that draw the Empire State Express. We can then by means of equation (1) determine the speed that could be made, as follows:

$$V = \frac{P}{R_1 + R_2} \text{.......} \quad \text{............}(1)$$

$P = 2100$ h.-p. $= 69{,}300{,}000$ foot-pounds per minute.

$R_1 = 270 \times 6 = 1{,}620.$

$R_2 = .594\,V = \frac{52.34\,V}{88} =$ head resistance at one foot per minute.

$$V = \frac{69{,}300{,}000}{1620 + .594\,V}.$$

Multiplying both factors by (1620+.594 V,
V (1620+.594 V)=69,300,000.

Also, $.594\,V^2 + 1620\,V = 69{,}300{,}000$. Whence, $V^2 + 2727.27\,V = 166{,}666{,}666$, and $V = -\,1363.63 \pm \sqrt{116{,}666{,}666 + (1363.63)^2} =$ 9522 feet per minute= 108 miles per hour.

This result shows that with the same expenditure for coal that is required in a steam locomotive to maintain a speed of 70 miles per hour with a train of the weight of the Empire State Express electric motors could make a speed of 108 miles per hour.

These figures are just as favorable as they can be made for steam. The weight of train has been taken at 270 tons, whereas it should not be over 200 if the motors are assumed to be mounted on the trucks of one of the cars. But in order not to be charged with unfairness by those who may insist that a separate motor should be used, the weight has been left high enough to permit of such an arrangement.

The foregoing shows that much higher speed is possible with electric motors than with steam locomotives, from the fact that the former can be made of much larger capacity; but when the construction and action of the locomotive is taken into consideration it will be found that, aside from the inability to develop the necessary energy, there are mechanical obstacles that limit its capacity.

The moving plant of a motor rotates, and, if properly balanced, there is no limit practically to its velocity; but on a locomotive the moving parts reciprocate, and therefore the velocity is limited. A locomotive to make a speed of 80 miles per hour would have to make about 350 revolutions per minute, which would give a piston speed of about 1,460 feet. Such a velocity in a stationary engine would be considered far beyond practical limits. What is usually called a high-speed engine is one in which a piston velocity of from 500 to 600 feet per minute is attained. Now if this is high for a stationary machine it certainly should be high for a locomotive. Nevertheless the latter runs at more than double this velocity, and this fact no doubt accounts for the enormous wear and tear. It has been proposed to overcome this difficulty of high rotative velocity by increasing the diameter of driving wheels. This would relieve the machine to a certain extent of the strain that it would be subjected to with smaller wheels, but it would not render much higher speed possible, because then the ability of the boiler to furnish the necessary supply of steam would limit the capacity. It may be conceded that locomotive boilers have not yet reached their utmost capacity and that it is possible to obtain still greater evaporation, but it must be admitted that no very great increase is possible; therefore much higher speed than is now made cannot very well be expected.

ELECTRIC CHAISE FOR QUEEN VICTORIA.

"Invention" says that an electric chaise was ordered by the late Prince Henry of Battenberg for Queen Victoria. The vehicle, which is not yet finished, is built upon a double framework of tubes with a head tube for steering, such as a bicycle has, the steering handle being somewhat like that used in Bath chairs. The body of the carriage is composed of aluminum, and it runs upon three wheels, fitted with Michelin tires; the propelling force is a dynamo driven with Fulmen accumulators.

THE WOOD AND MILLER SAFETY CONTROL DEVICES.

A patent has just been granted to W. M. Wood and J. C. Miller, of Elmira, N. Y., for an invention designed to stop the cable of a cable railroad from the platform of a car at any point of the road, by forming an electric contact, sending the current to the power station and throwing out the clutch that connects the cable drum with the main shaft, or stopping the engine. It affords quick and positive means within the reach and control of the motorman to stop the cable in case of his inability to detach the grip from the cable and prevent the loss of life, limb and property. Messrs. Wood and Miller have invented several safety appliances for stopping engines, machinery, etc. Another invention of these gentlemen, which is especially adapted to electric-power houses, is one whereby an engine will stop itself automatically in case of racing or increase of speed to a dangerous degree, and will also throw out a circuit-breaker or switch and cut out the current from the dynamo, and prevent motoring by other dynamos connected on the line. About six months ago Messrs. Wood and Miller placed one of their engine stops and auxiliary governors in the factory of J. Richardson & Co., at Elmira, by means of which the factory engine will stop itself in case of racing, and can also be stopped by merely pushing a button from any part of the building. On March 25 a test of this machine was made, after six months' usage, and found in perfect working order. The auxiliary governor is both electrical and mechanical in its construction. The engine was raced by cutting out its governor, and was stopped electrically. The electric wires were then cut out and the engine stopped by the mechanical device. The test was highly satisfactory to Messrs. Richardson & Co., as well as to the inventors. The Elmira Safety Appliance Company have secured control of the inventions, and are now ready to manufacture and place them on the market.

A TUG TO BE FITTED UP WITH APPLIANCES FOR TRANSMITTING POWER.

The Alaska "Searchlight" contains the outlines of a novel scheme on foot for developing the mineral belts of Alaska adjacent to the coast. The author of this scheme is W. F. Mills, who is largely interested in Alaska mining property.

The proposition is to fit up a tug of about thirty tons burden with electric attachments consisting of dynamos, two or three miles of insulated wire, and a diamond drill with attachments for boring about 300 feet. Power will be supplied from the tug to operate the drill. All of the attachments will be made in sections weighing not more than seventy-five pounds each, so that they can be easily packed from tide water to the base of operations. The tug will carry a crew of about ten men. In most places, if necessary, Indians will be employed to do the packing. Part of the crew will be engaged in supplying the fuel necessary, which is plentiful in any locality in Alaska. While the drill is being sunk in one location men will be sent ahead to prospect for another, so that the drill will be kept in constant operation, showing just what the ledges operated upon contain. The drill will bore from twenty to forty feet per day, which will be a rapid way of testing the different mineral belts, of which there are many throughout Southeastern Alaska. Admiralty Island alone, if properly developed, should furnish enough ore to keep 10,000 stamps going constantly for an indefinite period.

THE KINGS RIVER ELECTRIC POWER COMPANY has been formed at Reedley, Cal., with a capital stock of $360,000. The directors are S. T. Earl and J. S. Jones, of Reedley; J. Sibley, of Dinuba, and C. G. Wilcox and W. S. Hammond, of Visalia.

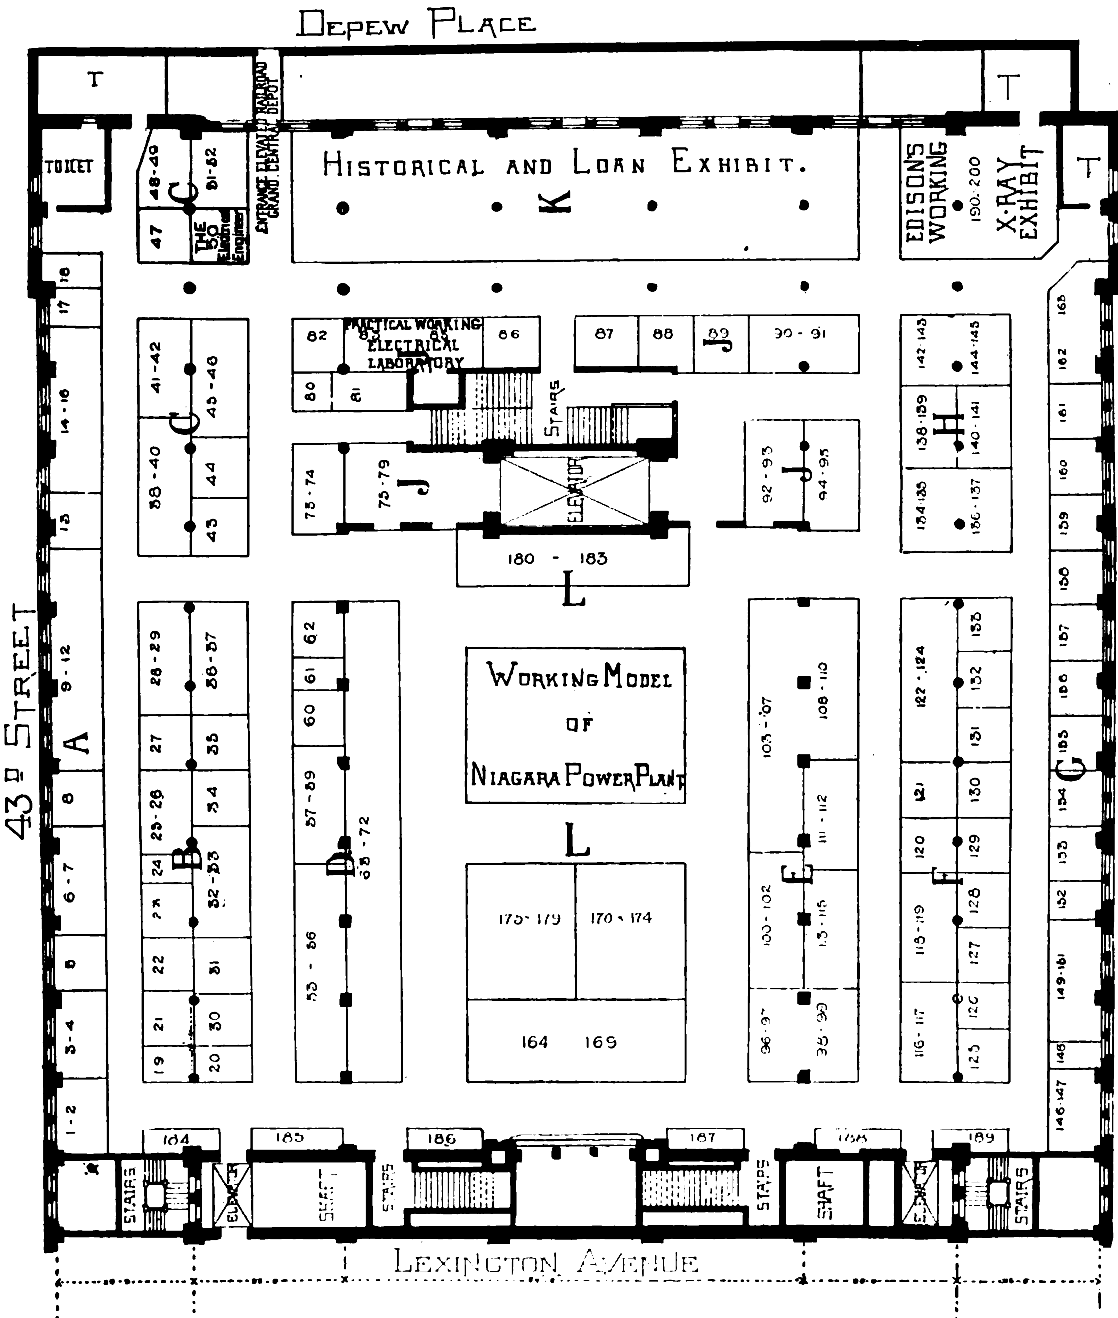
Exhibition Notes.

WHERE EXHIBITORS WILL BE LOCATED.

THIS week we are enabled to publish a preliminary plan of the main floor of the National Electrical Exposition, showing the location of exhibitors there, as far as at present arranged. In addition to this floor there is also the ground floor, where the boiler plant of 1,200 horse-power and some 12 or more engines and dynamos will be found in combination, each of the 12 engines having its own specific dynamo to drive. It is said that this in itself will be the finest display of direct driven apparatus ever made, and will show how far that tendency has gone.

The key to the plan herewith gives the letter and space number for each exhibitor, and thus locates about one-half of those who will be represented at the exposition. Other allotments of space are being made as rapidly as possible:

Adams-Bagnall Electric Co., Cleveland, O., B. 28-29.
American Electric Heating Corporation, Boston, Mass., B. 60.
Anchor Electric Co., Boston, Mass., G. 155.
American Watchman's Time Detector Co., J. 87.
Birdsall Electric Manufacturing Co., New York, A. 17.
Bishop Gutta Percha Co., New York, A. 5.
Bossert, Wm. F., Utica, N. Y., G. 148.
Boynton Multivolt Battery Co., New York, H. 140.
Bradford Belting Co., Cincinnati, O., G. 146-147.
Bryan-Marsh Co., New York, F. 116-117.
Burry, John, New York, J. 80.
Buyers' Reference, A. 18.
Calculagraph Co., New York, F. 131.
Card Electric Motor and Dynamo Co., Cincinnati, O., D. 62.
Carpenter Enamel Rheostat Co., Hoboken, N. J., G. 156.
Chapin-Douglass Electric Co., New York, B. 23.
Clark Electric Co., New York, B. 35.



PLAN OF MAIN FLOOR, NATIONAL ELECTRICAL EXPOSITION.

Columbia Rubber Works Co., New York, F. 128.
Columbia Incandescent Lamp Co., St. Louis, Mo., 594-595.
Crocker-Wheeler Electric Co., New York, L. 175-179.
Crouse-Tremaine Carbon Co., Fostoria, O., B. 30.
Cutter Electrical Manufacturing Co., Philadelphia, Pa., H. 138-139.
Dale, Farrell & Co., New York, F. 130.
DeVeau & Co., New York, D. 185.
Diehl & Co., Elizabethport, N. J., F. 118-119.

Dixon, Jos., Crucible Co., Jersey City, N. J., F. 126.
Empire Self-Lighting Oil Lamp Co., E. 112.
Edison Electric Illuminating Co., New York, D. 63-72, J. 75-79.
Electric Storage Battery Co., Philadelphia, Pa., D. 53-56.
Electrical Engineer, The, New York, C. 50.
Electrician Publishing Co., Chicago, Ill., C. 48-49.
Electricity Newspaper Co., New York, C. 47.
Electrozone Co., New York, H. 142-145.
Excelsior Electric Manufacturing Co., E. 111-113-115.
Ferracute Machine Co., Bridgeton, N. J., G. 152.
Forest City Electric Co., Cleveland, O., B. 27.
Fort Wayne Electric Corporation, Fort Wayne, Ind., B. 25-26.
Gamewell Fire Alarm and Telegraph Co., New York, J. 73-74.
General Electric Co., Schenectady, N. Y., L. 180-183.
Gordon-Burnham Battery Co., New York, G. 157.
Hall, George P., & Son, New York, B. 184.
Holtzer-Cabot Electric Co., Boston, Mass., F. 125.
Huebel & Manger, Brooklyn, N. Y., E. 188.
India-Rubber and Gutta Percha Insulating Co., Yonkers, N. Y., A. 67.
Interior Conduit and Insulation Co., New York, E. 103-110.
Iron-Clad Rheostat Co., Westfield, N. J., G. 153.
Johnston, The W. J., Co., New York., C. 51-52.
Keuffel & Esser Co., New York., J. 90-91.
Lozier, R. T., New York, D. 62.
Metropolitan Telephone and Telegraph Co., New York., E. 96-99.
Mica Insulator Co., New York, F. 127.
National Carbon Co., Cleveland O., B. 22.
National Conduit Manufacturing Co., New York., B. 32-33.
New York Carbon Works, New York., H. 141.
Niles Tool Works Co., Hamilton, O., H. 134-137.

Weston Electrical Instrument Co., Newark, N. J., J. 89.
Worthington, Henry R., New York, B. 36-37.
Western Telegraph Construction Co., Chicago, L. 186-187.
Washburn & Moen Mfg. Co., Worcester, Mass., A. 14-15-16.

EARLY DYNAMOS AT THE EXPOSITION.

Cornell University is among the many contributors of interesting objects at the electrical exposition. It is in possession of the Gramme dynamo, built by Prof. W. A. Anthony as early as 1876, and exhibited as a great curiosity at the Centennial Exposition of that year. It was probably the first dynamo of practical form constructed on those lines in this country. It was used for arc lighting and for a great variety of purposes in those early days. It has remained in use ever since, and Dr. E. L. Nichols writes that even now they are using it at the university. The art has seen many remarkable evolutions, making this machine as great a curiosity in 1896 as in 1876, and it will be doubtless a center of attraction to all students of dynamo construction. Cornell is also exhibiting other things of interest, and its work for the success of the exposition is but natural in an institution that benefited so nobly from the first fruits of electrical invention and industry. It may be added that other very early dynamos are to be shown.

WHAT EXHIBITORS WILL DO.

As the time approaches for the National Electrical Exposition the plans for various exhibits approach maturity, and we are able this week to supplement with many items of interest the news already given.

The Nowotny Electric Company of Cincinnati inform us that they will exhibit their familiar ironclad dynamos and motors and a number of entirely new electric light specialties of their own manufacture.

Mr. R. B. Corey, of New York City, reports that his exhibit will consist of arc lamps for direct and alternating current, knife switches and Sun-Schmelzer-Nürnberg carbons for direct and alternating arcs.

The Standard Underground Cable Company will exhibit some reels of their cable, showing standard fiber insulated cables; standard paper insulated cables, and standard rubber cables. A specialty will be made of samples, representing some of their latest contracts. A rack for show purposes will also be included, carrying samples of their products for distribution. Messrs. G. L. Wiley, with an assistant; Vice-President Marsh, and J. R. Wiley, of Chicago, will be in attendance.

The Siemens & Halske Electric Company will install in connection with the Ball & Wood Company an operating 100-kilowatt direct-connected type "I" external armature dynamo, which is one of eight furnished for the Siegel-Cooper "Big Store." They will also exhibit some of their direct current arc lamps, which, although in wide use abroad, have not yet been pushed much in this country.

The Adams-Bagnall Electric Company, of Cleveland, will have in their exhibit arc lamps for every kind of circuit and in various styles of finish, including "black Japan," "oxidized copper," "oxidized brass," "oxidized silver," "yellow brass," "Japanese copper," nickel and aluminum. It will be one of the finest displays of arc lamps ever made. There will also be shown a quantity of the already well-known "A-B" incandescent lamps.

H. B. Coho & Co., of New York City, report that they will show a 40-kilowatt Eddy multipolar generator directly connected to an Ideal engine; also several 30-kilowatt machines in connection with other engines. In connection with Mr. Augustus Noll they will also exhibit a very fine switchboard. They are also expecting to show a number of small specialties, including electric heating and cooking apparatus, fiber graphite brushes, etc., and will distribute literature, price lists, etc., quite freely.

The General Electric Company are gradually working out their plans for a fine exhibit, part of which has already been referred to in these columns. In the main exhibition hall they will have, somewhat after the style of their Chicago World's Fair display, a handsome headquarters and general reception room, occupying about 400 square feet of space. As a "still" exhibit they will show a few of their latest long-burning arc lamps, a selection of their inclined-coil instruments, and a few meters. A special feature will be made of a fine collection of bromide prints to illustrate the latest types of apparatus they have developed and some of their latest representative installations. So much importance does the company attach to the meeting and exposition that it has appointed a convention committee, as follows: S. D. Greene, chairman; C. T. Hughes, vice-chairman; F. M. Kimball, secretary, A. D. Page, lamp works; T. Beran, New York Supply Department, and F. N. Boyer, of the Chicago Supply Department. The company will also be represented by Messrs. H. J. Buddy, representing the Philadelphia office; A. F. Giles, Atlanta; W. J. Ferris, Chicago, and C. B. Davis, A. R. Bush, C. S. Haley and A. W. Ives, representing the Boston office, together with representatives from the railway, power and mining departments and the New York office.

The Electrozone Company, Mr. A. E. Woolf, its expert and inventor in charge, will have one of the most novel and striking exhibits in the whole building. Mr. Woolf, as is well known, electrolyses salt water and uses the resultant liquid as a disinfector and purifier. He will probably show a little model of Riker's Island, with real garbage, which he will disinfect in sight by playing electrozone on it. He will also illustrate his sewage treatment method, the killing of harmless germs to prove what can be done in germicide, and will also give an elaborate microscopical display. In addition to this he will have a working model of his bleaching process, with which he will treat wood pulp. He will also exhibit his alkali process, decomposing a saline solution, chlorine on one side and alkali on the other. Those who know Mr. Woolf's fertility of resource will not be surprised to find his space one of the nightly centers of attraction.

The Metropolitan Telephone Company's Exhibit, realizing the impracticability of adequately exhibiting the working of its complicated and extensive plant in any

reasonable space, will make an exhibit illustrative of its New York City service as viewed from the user's standpoint. The manner in which this will be carried out involves nevertheless a more elaborate installation than might appear from the exhibit proper, as the company will place telephone stations at a number of exhibitors' spaces, as well as at points where service is desired by the Exhibition company. These stations will be connected to a switchboard in the company's space, thus forming a small exchange within the exhibition itself. This service will be furnished without charge to the exhibitors and to the Exhibition Company by the Metropolitan Telephone Company, which will furnish the entire installation and maintain the service at its own expense. Besides the switchboard the company will install in its own space four silence booths of different types, each equipped with telephone instruments of the various styles used by New York City subscribers. These will all be working stations connected with the Thirty-eighth Street Exchange, and will be available to visitors to the exhibition in the same way as an ordinary public pay station. This remarkably useful form of exhibit will no doubt be highly appreciated by exhibitors, who cannot fail to realize the convenience of being placed in easy communication with each other and with their home offices. The exhibit proper will afford the public ample illustration of the excellent service furnished by the Metropolitan Company and of the high grade of equipment provided for public and subscribers' stations. Those visitors who display particular interest in the operation of a city telephone system will be invited to visit one of the company's large exchanges where they can examine in detail the nature and operation of the plant, which are practically impossible of reproduction in an ordinary exhibition.

The Payne Engine Company, of 41 Dey street, New York City, and Elmira, N. Y., will have one of their new type direct connected engines of 50 horse-power capacity connected to 25-kilowatt Card generator. This machine will undoubtedly be of unusual interest, from the fact that it will have an improved inertia governor of an exceedingly simple form of construction, and one for which are claimed very superior results. The governor consists of but two pieces and one bearing, thus reducing friction to the minimum and the chances of disarrangement. It is stated by the manufacturers that this governor will move through the entire range, viz.: from 0 to 5/8 cut-off, in less than 1-5 of a second; and it overcomes what is commonly known as dancing in the centrifugal governor. The Payne people will have another feature which will attract a good deal of attention. It is an automatic return oil circulation system, by means of which the oil is delivered in a stream to the main bearings by gravity and drained to a central point at the bottom of the base. By means of a small oil pump working on the rocker arm of the valve rod, it is pumped to a receptacle on top of the frame, where it is filtered and re-used. Carefully designed oil guards prevent any oil being thrown from the engines, and at the same time it is not the inclosed type. The Payne Company will be represented at the exposition by S. H. Payne, N. B. Payne and F. N. Jewett, of the New York office.

The Ironclad Rheostat Company, of Westfield, N. J., will have an interesting exhibit to consist of goods that they manufacture, some of which will be in operation. The display will consist of theater dimmers, rheostats for storage batteries, motor starters, speed controllers, standard and special resistances, etc. The company will be represented by Mr. Charl D. Doubleday and Mr. G. L. Colgate.

The Card Electric Motor and Dynamo Company, of Cincinnati, will have a large and striking exhibit in the hands of Mr. R. T. Lozier, their general Eastern agent. It will comprise a 25-kilowatt generator directly connected to a Payne engine. Current will thus be furnished to a Card motor operating a Hoe press, the armature of the motor being directly connected to the shaft of the press in the place of the pulleys. Another Card motor will be shown directly connected to a 37-inch Niles boring mill. A third motor will be directly connected to a Niles 6-inch radial drill, and a three horse-power motor will be belted to a horizontal boring mill. This well-selected exhibit will be supplemented by some special features that are now being worked up.

Mr. A. O. Schoonmaker, New York City, will exhibit sheet mica, showing it in the uncut form, cut to sizes, stamped in segments, washers and in various forms. The exhibit is intended directly for the guidance and information of the trade.

The Interior Conduit and Insulation Co., of this city, have taken considerable space, and will show in operation a printing press run by direct connected Lundell motor; exhaust fan outfits, 60, 36 and 12-inch; direct connected generating set; Lundell power motors, Lundell generators. Lundell desk fans and ceiling fans, Lundell dental outfits, Lundell emery wheel grinder, Lundell buffing machine and Lundell organ-blowing outfit. The latter will be attached to a Mason & Hamlin organ, which will be played each evening. The company will also exhibit their complete system of plain, brass-armored and iron-armored insulating conduits, as well as their complete underground conduit system. The space will be ornamented by an illuminated electric sign, 30 feet in length. The following gentlemen will be specially in attendance to explain the various novelties: D. C. Durland, G. H. Kimber and E. B. Kittle.

The Columbia Rubber Works will have a display, limited strictly to hard rubber specialties and electrical hard rubber appliances, such as push buttons, telephone receivers, hard rubber sheet and tubing, and all goods which go in that class.

The Harrisburg Foundry and Machine Works will have a combination exhibit of one Ideal engine, direct connected to a 40-kilowatt Eddy generator. W. R. Fleming & Co. will have commercial charge of the exhibit in association with H. B. Coho & Co.

ARRANGEMENTS AT THE MURRAY HILL HOTEL.

In designating the Murray Hill Hotel as its official headquarters for its nineteenth convention, the National Electric Light Association has acted wisely. The hotel is not only one of the finest and most beautiful in New York, as well as one of the best conducted, but it is distant only a couple of blocks from the meeting room and the exposition building.

The management of the hotel, having in view the comfort of its guests, has determined to reserve all possible space for their proper entertainment. It has stipulated, therefore, with the association that none of the guests make use of any part of the hotel for exposition purposes, or display any signs or placards in the halls or corridors. This will restrict the exhibition and trade features to the place where they belong, and will leave the hotel as the undisturbed center of the social events of this memorable occasion.

N. E. L. A. TRANSPORTATION.

C. O. Baker, Jr., Master of Transportation, writes that arrangements have been made whereby delegates on the line of the Chicago and Alton road can use that road to Chicago and connect with the electrical special at that point for a fare and one-third, on the certificate plan. This will enable the St. Louis delegates to leave that city at 11:30 p. m. and reach Chicago at 8:30 a. m. the following day, which will enable them to remain in the latter city until the time the electrical special leaves, namely, 5 p. m., Saturday, May 2.

POSTAL WIRES FOR THE OPENING CEREMONIES.

In connection with the opening ceremonies of the National Electrical Exposition, when it is proposed to start the machinery by a circuit that has first looped in the whole continent, the Postal Telegraph Cable Co., through its Vice-President, Mr. W. H. Baker, has very courteously offered its fine service between New York and San Francisco for the purpose. The Postal Company has been equipping its lines with heavy copper circuits, and believes that it can illustrate rapidity of working by the instantaneity of its transmission on May 4, when the mere pressure of the golden key will flash the signal to the Golden Gate and back to the exposition building, in the twinkling of an eye. Arrangements are now being made with the Postal officials for the execution of this interesting plan, with the co-operation of the long string of offices scattered over the 6,000 miles of wire.

STORING NIAGARA ENERGY FOR THE EXPOSITION.

The announcement was made last week of the generous offer of the Western Union Telegraph Company of two wires from Niagara, with which to bring current from the power plant there to run the model of the plant at the exposition. These wires will be available in the evening, and the question thus arose as to what should be done in the way of running the model the rest of the time during each day. Mr. A. S. Brown, the electrical engineer of the Western Union Telegraph Company, suggested that it would be a comparatively easy thing to ship a few storage batteries up to Niagara, charge them there and bring them down for the purpose. This simple but shrewd suggestion has been acted upon, and the Electric Storage Battery Co. of Philadelphia, through Mr. Charles Blizard, its representative in this city, has placed at the disposal of the exposition all the batteries that may be needed, with the permission that this stored Niagara energy can also be turned loose on any other exhibit at will.

There will thus be exhibited the energy of Niagara in a "live" form, coming over the wires in the shape of an alternat-

ing phase current to drive the model by a phase motor; and the stored Niagara energy, which will, of course, be applied to a direct current motor, which will also run the model part of the time. A more interesting illustration of the flexibility of electrical power transmission than this could hardly be desired, as it practically embraces the whole field of modern methods and appliances.

THE EVOLUTION OF THE STOCK TICKER.

An exhibit that is sure to arrest the attention of the numerous visitors to the exposition will be that which shows a stock ticker system in full working operation. To watch the tape unroll with the curt little signs on it is one thing, but to see how the information that means so much to the financial world is gathered and put on the circuits is another matter of interest to everybody. The development of the modern stock-ticker system, so strikingly American, is the result of much ingenuity and enterprise, and has brought many brilliant electricians to the front.

With the object of assisting to a better understanding of the subject, the executive of the Gold and Stock Telegraph Company has generously authorized its superintendent and electrician, Mr. George B. Scott, to place at the disposal of the exposition management a number of old instruments that will be useful in showing how the system as it exists to-day has been worked out to its present stage of efficiency and celerity. Mr. Edison and others are also contributing apparatus of this nature, rendering the display one of unusual value, as such electrical machinery has never been brought together before in this instructive manner.

A LARGE PATENT OFFICE EXHIBIT.

In view of the importance of the occasion, the exhibit of the United States Patent Office at the National Electrical Exposition will be made one of unusual size and interest. As now arranged by the Department, under the instruction of Mr. S. T. Fisher, the acting commissioner, it will include no fewer than 361 separate models of electrical devices, apparatus, machinery and appliances, many of them embodying the fundamental and elementary ideas upon which the modern electrical arts have been founded. These models will occupy over 300 lineal feet, and will be carefully grouped and classified, so that students, of whatever character, can follow the general lines of growth or evolution.

PROFESSOR ELIHU THOMSON AT THE EXPOSITION.

In spite of many pressing engagements, Prof. Elihu Thomson is kindly preparing for the National Electrical Exposition a very interesting personal exhibit. He hopes to ship it to New York from New England in a few days. He has been requested by the management to include in it some of the working apparatus illustrative, in many beautiful ways, of the "repulsion phenomena," his classic investigation of which some years ago is well remembered by all electricians. An endeavor will also be made to secure a lecture from him during the exposition, as it is understood that he will be in New York at that time, and is one of the most successful lecturers of the time in explaining electricity popularly and clearly. A bust of Professor Thomson is now being made by the Riccinilli Bros., of New York, under the direction of the sculptor, Mr. Robert Kraus, of Boston. It is expected to be finished by the end of the month, and the original has consented to its inclusion in the collection of busts and pictures that will adorn the space of the Loan and Historical Exhibit Committee.

ADDITIONAL EXHIBITORS.

During the past week the already long list of exhibitors at the National Electrical Exposition has received several additions, some of them quite large and important. Among these may be mentioned the Joseph Dixon Crucible Company, the Sprague Electric Elevator Company, the Westinghouse Electric and Manufacturing Company and the United Electric Light and Power Company, of this city. The three concerns last named are understood to have taken for their various exhibits about 1,000 square feet. The pressure for space has indeed become embarrassing.

CONTRACTS FOR THE EXPOSITION.

The National Electrical Exposition Company has awarded the following contracts, which are now being carried out: William Andrews, steam piping and fittings; Garrett Wright, boiler and engine foundations; J. E. Phelps, exclusive catalogue privilege.

SOCIETY AND CLUB NOTES.

PROF. THOMSON BEFORE THE ELECTRIC POTENTIALS.

At the annual meeting of the Boston "Electric Potentials," and after the dinner at the Hotel Thorndike, on April 22, Prof. Elihu Thomson will entertain the society by a copiously illustrated lecture on the Röntgen X-ray. Ladies will also be present.

X-RAYS BEFORE THE QUIDNUNC CLUB.

The Quidnunc Club is an uptown organization based on the lines laid down by the Nineteenth Century Club, for the discussion of live topics of the hour. At its April meeting last week, before a large and fashionable audience, Mr. Max Österberg, of Columbia College, gave an admirable popular lecture on the Röntgen ray, with experiments, in which he was assited by Mr. Lovejoy, using an array of Geissler and Crookes tubes, and showing a number of shadow pictures on the lantern screen. After the lecture everybody in the audience was given an opportunity to study anatomy, and the excellent Edison and Le Roy fluoroscopes provided were in great demand, particularly by the ladies, who wished to see how their hands looked when seen through gloves, books, blocks of wood, etc. The lecture was a brilliant success in every respect. One of the auditors, Mr. R. W. C. Merington, mentioned the interesting fact that the last electrical lecture he had heard previous to this was one by Faraday, a personal friend of his, in England, in 1854.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

Mr. D. McF. Moore will deliver his lecture on vacuum-tube lighting at the headquarters, 12 West Thirty-first street, on April 22, at 8 p. m. The room will be lit by tubes. Mr. Moore will also illustrate his lecture by lantern slides. Members and their friends will find the occasion one of much interest and importance.

NEW YORK ELECTRICAL SOCIETY.

The Sprague Electric Elevator Company has courteously invited the society to visit its new works at Watsessing Junction, N. J., on the evening of Friday, April 24, for the purpose of seeing how modern high speed electric elevators are constructed and operated. In addition to the opportunities thus presented for studying the subject in all its details, Mr. Sprague has kindly consented to give a brief address on some of the more interesting features and problems of electric elevator work, especially in relation to extremely tall buildings. The most convenient train for reaching the works will be that leaving foot of Barclay street, and foot of Christopher street at 7:50 p. m., D., L. & W. Railroad. Return trains will leave Watsessing every forty minutes up to 12 o'clock. A collation will be provided.

LEGAL NOTES.

A STANDARD UNDERGROUND CABLE CO. SUIT.

Mr. R. B. Waring, formerly connected with the Standard Underground Cable Company, and the original owner of many of its valuable patents, has recently entered suit against Mr. George Westinghouse, Jr., to recover the value of 10,000 shares of stock in said company. The well-known names of the litigants and the large amount involved make the case one of considerable interest.

Mr. Waring claims that the stock in question was transferred by himself to Mr. Westinghouse at the time that Mr. Westinghouse became connected with the company in March 1886; and that the stock was to have been held in trust and for his benefit.

The defense of Mr. Westinghouse to this suit was substantially that the stock in question had been given him outright, to secure his active interest and influence in favor of the company, which was then a new undertaking, and that there was no agreement or understanding that he held the stock for Mr. Waring, and that nothing is due to Mr. Waring on account thereof.

The case was brought to a sudden termination on the 9th inst., when the plaintiff withdrew his suit. The testimony on the main issue, viz., whether Mr. Westinghouse should account to Mr. Waring for the stock in question, appears to have been largely in favor of Mr. Westinghouse up to the time the suit was withdrawn.

MISCELLANEOUS.

MONOCYCLIC DISTRIBUTION AT MIDDLETOWN, OHIO.

ONE of the most interesting modern stations in this country, and the first perhaps which has a larger motor load than a lighting load, is that at Middletown, Ohio, operated by the Middletown Electric Light and Power Company.

It is now some four months since Mr. E. H. McKnight, president and general manager, determined on an increase in his station, which up to that time had operated on a small scale only. The conditions with which he was confronted showed

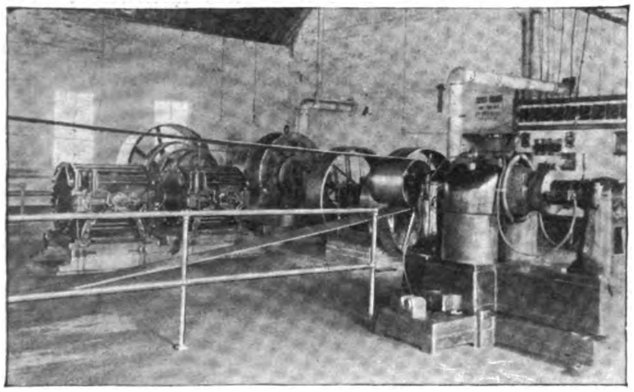

FIG. 1.—THE GENERATING STATION, MIDDLETOWN, OHIO.

the necessity of a system of distribution which would allow him to cope with a large demand for current for motor service during the day and a similarly large one for lighting after dark. As best satisfying these conditions, Mr. McKnight selected the monocyclic system of the General Electric Company.

The power-house is large and well ventilated and is situated near the center of the city in an ideal location for an electric station. It fronts on the Cleveland and Cincinnati Canal, while immediately behind it are the tracks of the M. & C. R. R. Water for the station is taken from the canal in front, and the necessary coal is shoveled directly into the bins from the cars standing on the tracks behind.

The steam equipment consists of two Brownell & Dayton boilers, furnishing steam to one 250 horse-power Russell engine and one 100 horse-power Ball engine. The first runs at

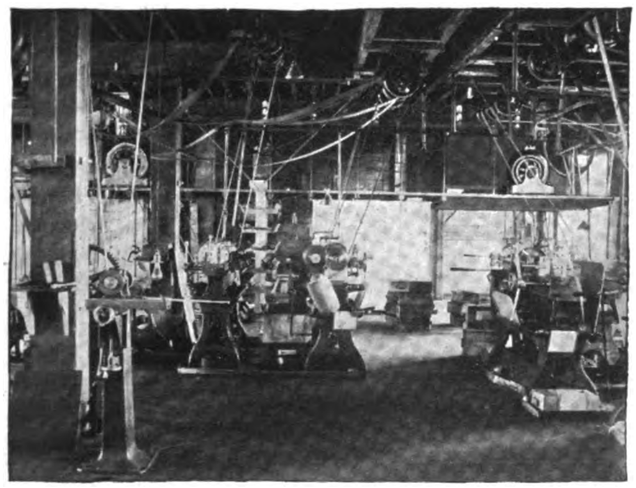

FIG. 2.—CORNER OF MACHINE ROOM, SHOWING INDUCTION MOTORS, IN MIAMI CYCLE FACTORY.

164 revolutions, and drives from a countershaft the new monocyclic generator and two T.-H. 75-light arc dynamos; the latter runs at 285 revolutions and drives a D-62, T.-H. bipolar direct-current low voltage machine. The monocyclic generator is a standard 12-pole machine, running at 600 revolutions. It is rated at 150 kilowatts at 1,040 volts, and is excited by a 1½ kilowatt exciter. The D-62 furnishes current for direct-current motors scattered throughout the city. The arc machines operate lights in the streets, while the monocyclic is wired for about 180 horse-power in motors and 2,000 lights. If all the lights and motors were operated at the same time the total amount of energy required from this generator would be about double its capacity, and its power to cope with the conditions illustrates forcibly the advantages of the monocyclic system. During the day the lights burning are comparatively few, while the motor load is at its maximum. This condition is reversed after dark, when tthe motor load drops off and the lighting load rises in turn. The generator, which runs 23 hours per day, is worked continuously at its highest efficiency and satisfactorily fulfills its double duty without sparking or noticeable heating.

The most important client of the Middletown station is the Miami Cycle and Manufacturing Company, whose factory is located about one mile distant. It takes current for 180 horse-power in motors; for 800 incandescent lamps, of which 400 are usually in use, and for six arc lamps. The Cycle Company turns out about 200 wheels a day and employs from 500 to 600 hands.

The current is transmitted from the station to the works over two mains and a teaser wire at about 1,000 volts and is reduced to about 115 volts in six 30,000 watt oil cooled transformers installed in a small house erected in the angle of the L-shaped main building. All the motors derive their supply of current from these transformers connected in multiple. The lighting circuits are taken off from two 7,500 and one 15,000-watt transformers. The primary wires from the station are passed through a station wattmeter just before they arrive at the transformers, and thus the consumption of energy in both lighting and motor circuits is measured in one instrument.

The secondaries run from the small sub-station north and

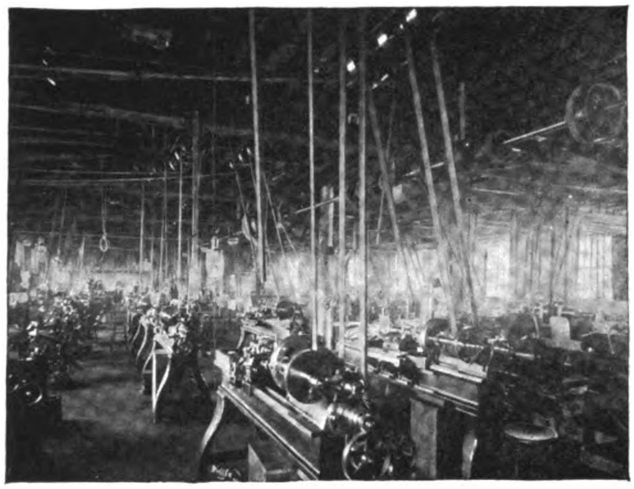

FIG. 3.—MACHINE ROOM, DRIVEN BY INDUCTION MOTORS, MIAMI CYCLE FACTORY.

south to the motors and lights in the two legs of the L. Those running south operate in the machine shop three 20 horse-power motors, each belted to a long line of shafting, from which run 80 belts.

The feeders running north supply energy to three 30 horse-power motors, two of 10 horse-power and two of 5 horse-power supplying power to the drill room, the pattern room and the frame-making department.

A large portion of the power which comes into the factory is used in the polishing room, where 35 double polishing lathes run incessantly. These are operated at present by two 30 horse-power motors. The remaining 30 horse-power motor in the north section drives a 48 inch exhaust blower, which carries away the dust from the polishing room. Located in the assembling department is a 5 horse-power motor, which operates a freight elevator of 1,500 pounds at 60 feet per minute capacity, which runs up and down through the room.

All these motors are of the General Electric induction type, without commutator, collector or moving contacts. They are set up on platforms swung from rafters in the rooms, an arrangement rendered possible by the fact that they require no attention beyond an occasional oiling, and thus occupy no floor space.

In addition to the load at the Miami Cycle Works, the monocyclic generator supplies current to 500 to 600 lights throughout the town, and 650 incandescents in the Sorg Opera House.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED APRIL 14, 1896.

Alarms and Signals:—

SIGNALING SYSTEM FOR ELECTRIC RAILWAYS. F. Bathurst, Schenectady, N. Y., 558,028. Filed July 15, 1893.
Signal and block lights located at either end of a section of track, with a two-way switch connecting the block lights with ground in one position and with the trolley in the other.

Primary Batteries:—

BATTERY. W. Morison, Montclair, N. J., 558,091. Filed May 8, 1894.
An invertible single fluid battery.

Conductors, Conduits and Insulators:—

ELECTRIC WIRE CLEAT. F. B. Evans, Clinton, Mass., 558,165. Filed Aug. 26, 1895.
Comprises two separate and similar parts having interlocking faces.

Distribution:—

TRANSFORMER AND METHOD OF COOLING SAME. W. S. Moody, Lynn, Mass., 558,090. Filed Jan. 17, 1896.
Employs coils of wire surrounded by an iron core, and an insulating medium flowing down the outside of the core in the film.

Dynamos and Motors:—

ARMATURE WINDING. A. F. Batchelder, Schenectady, N. Y., 558,027. Filed Jan. 25, 1896.
An armature winding made in the form of a cloth, in which the conductors form one element and suitable insulating material the other.

COMMUTATOR. D. P. Thomson and A. R. Goranson, Schenectady, N. Y., 558,120. Filed Dec. 19, 1895.
An automatic ventilating commutator constructed with radial fan, air passages, deflectors and an annular chamber having outlets for the air at a point above the interior of the commutator.

CARBON BRUSH HOLDER FOR ELECTRIC MACHINES. W. E. Knowlton, Portland, Me., 558,184. Filed Feb. 19, 1896.
Details of construction.

ALTERNATING CURRENT MOTOR. H. L. Tyler, Corning, N. Y., 558,239. Filed July 10, 1894.
A synchronous motor with commutator for the field current.

Electro-Metallurgy:—

APPARATUS FOR ELECTROLYTIC PRODUCTION OF ZINC. R. Encke and O. Frölich, Berlin, Germany, 558,052. Filed July 31, 1895.
Partition plates extend lengthwise in the cell and means are provided to freely circulate the electrolyte.

Lamps and Appurtenances:—

COMPOUND MOLD FOR FORMING INCANDESCENT LAMP BASES. J. Hanny and A. Pederquist, Schenectady, N. Y., 558,070. Filed Nov. 29, 1895.
Details of construction.

INCANDESCENT LAMP. K. O. E. Trobach, Pankow, Germany, 558,122. Filed April 18, 1894.
An electric lamp comprising a bell-shaped incandescing body of flexible and spongy carbon.

Miscellaneous:—

METHOD OF AGING PERMANENT MAGNETS. E. P. Cox, Lynn, Mass., 558,045. Filed Feb. 21, 1896.
Consists in revolving an electrical conductor in the field of a permanent magnet, thereby cutting the lines of force, reducing the flux, and causing the remaining flux to be permanent.

ELECTRIC TRAP RELEASE. J. A. R. Elliott, Kansas City, Mo., 558,051. Filed July 11, 1895.
Employs electromagnets.

ELECTRICALLY ACTUATED DENTAL PLUGGER. A. W. Browne, Prince's Bay, N. Y., 558,153. Filed Nov. 6, 1895.
Details of construction.

PROCESS FOR ELECTRIZING WATER FOR HEATING PURPOSES. P. Huber, Saginaw, Mich., 558,176. Filed April 1, 1895.
Comprises the manufacture of oxygen and hydrogen gases by the electrization of water and storing and using these gases for heating.

METHOD OF UTILIZING SALINE SOLUTIONS. C. N. Waite, Rumford, Me., 558,240. Filed March 19, 1894.
Employed in the treatment of wood fiber, for bleaching.

METHOD OF UTILIZING SALINE SOLUTIONS. C. N. Waite, Rumford Falls, Me., 558,241. Filed Oct. 8, 1895.
Relates to above.

ELECTRICALLY OPERATED MEANS FOR CONTROLLING VALVES. C. M. Bush, Bristol, Conn., 558,256. Filed Jan. 24, 1895.
A double magnet with reciprocating armatures connected to a valve-controlling device.

ELECTRICAL FURNACE. M. R. Conley, Brooklyn, N. Y., 558,357. Filed Sept. 25, 1895.
Comprises a vessel of a composition containing carbon, integral arms on opposite parts of the vessel of the same material, and terminals of an electric circuit connected to said arms.

ELECTRIC MINE CAGE AND ELEVATOR. C. J. Cutler, Butte, Mont., 558,450. Filed June 26, 1895.
Details of construction.

TEMPERATURE REGULATOR. H. Gillette, Highland, Park, Ill., 558,453. Filed July 19, 1895.
The valves have three positions instead of two.

ELECTRICAL HAIR CUTTER AND SINGER. F. M. Bell, New York, 558,465. Filed March 22, 1895.
A comb, wire or bar stretched along the comb, the electrical connections and means for closing and breaking the circuit.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. H. M. Brickerhoff, Chicago, Ill., 558,033. Filed June 13, 1895.
Provides an arrangement of the meeting ends of the sections.

ELECTRIC RAILWAY. L. W. Reid, Mound, Tex., 558,110. Filed Aug. 8, 1895.
Conductor is placed at top of conduit. Contact is made by trolley and a guide wheel is employed to maintain contact.

ELECTRIC RAILWAY SYSTEM. W. M. Brown, Johnstown, Pa., 558,151. Filed Nov. 29, 1895.
A contact box for electric railways, having a plurality of magnetic conductors substantially insulated magnetically from each other and having a recess or cavity between them into which the contact member is adapted to enter.

ELECTRIC RAILWAY. H. L. Tyler, Corning, N. Y., 558,238. Filed July 11, 1894.
Comprises a working circuit composed of track rails, a plurality of transformers connected in multiple arc with said working circuit, and a primary inducing current charged with alternating currents of high potential and composed of an independent insulating outgoing conductor, and a return leg formed by one side of the track or working circuit.

UNDERGROUND SYSTEM FOR ELECTRIC RAILWAYS. A. S. Krotz, Springfield and W. P. Allen, Chicago, Ill., 558,283. Filed Aug. 23, 1895.
A series of sectional tubes inclosing a conductor, contacting devices supported on said tubes and a connection from said conductor to each of said contacting devices.

CONDUIT OR SUBWAY FOR ELECTRIC RAILWAYS. A. S. Krotz, Springfield, O., and W. P. Allen, Chicago, Ill., 558,284. Filed Dec. 2, 1895.
Provides sectional contacting rails doubly insulated from the conduit.

ELECTRIC RAILWAY. D. N. Osyor, Newark, O., 558,303. Filed Jan. 23, 1889.
Especially designed for mine work.

ELECTRIC RAILWAY. C. F. P. Stendebach, Leipsic, Germany, 558,322. Filed March 7, 1895.
Contact is made between the underground conductor and the contact rail by a depression of the latter.

TROLLEY ATTACHMENT FOR ELECTRIC CARS. R. Skeen, Madison, Ill., 558,429. Filed Sept. 9, 1895.
A mechanism placed in an electric circuit with the trolley and adapted to check the upward movement of the trolley when the latter is disengaged from the trolley wire.

Regulation:—

SAFETY DEVICE FOR ALTERNATING SYSTEMS. E. J. Berg, Schenectady, N. Y., 558,031. Filed Oct. 5, 1895.
Means for supplying an interposed electromotive force of displaced phase to the motor, such means being brought into operation by an interruption of the supply in either of the circuits.

REGULATING INDUCTION MOTOR. W. B. Potter, Schenectady, N. Y., 558,104. Filed Jan. 15, 1896.
The fields are permanently connected in multiples and the circuits of their armatures closed through resistances.

REGULATING ALTERNATING CURRENT MOTORS. C. P. Steinmetz and E. J. Berg, Schenectady, N. Y., 558,119. Filed Dec. 28, 1895.
In combination, lines between which single-phase electromotive force is maintained, transformers having their primaries connected in series between such lines and having a secondary in reversed relation to the remaining secondaries of the transformers, lines leading from the secondaries, and a multiphase motor connected to such lines.

Switches, Cut-Outs, etc.

AUTOMATIC CUT-OUT AND RESISTANCE REGULATOR. E. B. W. Reichel, Gross-Lichterfelde, Germany, 558,109. Filed Dec. 27, 1895.
A stationary contact against which normally rests a movable contact.

RHEOSTAT PLATE. J. P. Ball, Philadelphia, Pa., 558,252. Filed Jan. 27. 1896.
A resistance plate having grooves and a wire bent upon itself to form a convolute and held in place within the groove.

PUSH BUTTON SWITCH. H. E. Nickerson, Cambridge, Mass., 558,299. Filed Dec. 7, 1895.
Details of construction.

ELECTRIC SWITCH. C. G. Bergquist, Chicago, Ill., 558,343. Filed June 25, 1895.
Adapted for attachment to electric fixtures and resembling a gas key in appearance.

ELECTRIC RHEOSTAT. F. H. Doane, Newton, Mass., 558,362. Filed Sept. 30, 1895.
The resistances are composed of one or more bars of highly resisting material.

Telegraphs:—

AUTOMATIC TELEGRAPH REPEATER. A. E. Collyer, Monmouth, Ill., 558,042. Filed Dec. 26, 1893.
Employs electromagnets to operate a pivotally mounted bar to open and close a circuit.

Telephones:—

CONNECTION FOR TELEPHONE APPARATUS. P. Rabbidge, Sydney, New South Wales, 558,106. Filed May 20, 1895.
The transmitter, receiver and battery remain constantly in the line circuit.

TELEPHONE SERVICE REGISTER. S. D. Field, Stockbridge, Mass., 558,167. Filed Aug. 21, 1895.
Employs a lever or device whose position is changed during the use of the telephone transmitter or receiver.

CALL COUNTER FOR TELEPHONES. S. D. Field, Stockbridge, Mass., 558,168. Filed Aug. 21, 1895.
Relates to above.

APPARATUS FOR COMPOSITE TRANSMISSION OF INTELLIGENCE. F. A. Pickernell, Newark, N. J., 558,310. Filed Oct. 17, 1894.
Provides means whereby the telegraphic induced currents are prevented from causing the telephonic signal receivers from giving false signals in the normal circuit.

TELEPHONE TRANSMITTER. A. W. Rose, New York, 558,313. Filed Aug. 29, 1895.
A diaphragm, electrodes, having a vibratory relation with each other, comminuted carbon mounted between said electrodes, and sloping flexible walls arranged at an angle to the direction of said vibration.

TELEPHONE TRANSMITTER. W. R. Cole, Detroit, Mich., 558,354. Filed May 15, 1894.
Employs a suspended oscillatory electromagnet in the circuit of the transmitter and carrying the outer electrode.

TELEPHONE BELL. R. D. Harrigan, Leadville, Colo., 558,385. Filed Nov. 5, 1895.
Provides means whereby the bell will continue to be sounded after the main circuit shall have been opened.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

O. C. WHITE COMPANY ADJUSTABLE INCANDESCENT LAMP-HOLDERS.

The reputation of the adjustable holders for incandescent lamps made by the O. C. White Company, Worcester, Mass., is now well established. The special claims made for these holders are: Their great range of movement, their smoothness and ease of action, their adjustability and ease of placement without attention to fastenings, their retention of lamp and shade at any angle above, below or at any position in relation to the object lighted; their protection of conductors from contact with moving parts of machinery, etc., and their adaptation as overhead pendants, wall brackets and standard supports. These claims have been so well vindicated that the

WHITE'S ADJUSTABLE LAMP HOLDER.

judges at the Columbian Exposition in Chicago gave to the holders the highest award it was in their power to bestow.

One favorite style, for direct attachment to desk or bench, is that shown in the accompanying engraving; it is especially adapted for easily placing the lamp in all positions through a considerable range while the operator is seated. It is much used by bookkeepers, sewing machine operators, jewelers, etc. Another holder, whose practical utility has been proved by many years' steady demand, consists of an ornamental bracket for desks, offices, libraries, etc. It has unrestricted movement to any position within a range of three feet, and has been found invaluable where the ability to make a quick change of the position of the lamp is essential.

ELECTRICAL SUPPLIES WANTED FOR THE GOVERNMENT PRINTING OFFICE, WASHINGTON.

THE Government Printing Office, through Thomas E. Benedict, public printer, is inviting proposals until May 7 for furnishing a quantity of articles for that department, as follows: 4,000 Columbia incandescent lamps, 16 c.-p., 110 volts, 50 watts, Edison base; 500 Columbia lamps, 25 c.-p., 110 volts, 78 watts, Edison base; 4,000 Perkins lamps, 16 c.-p., 110 volts, 50 watts, Edison base; 500 Perkins lamps, 25 c.-p., 110 volts, 78 watts, Edison base; 4,000 Packard lamps, 16 c.-p., 100 volts, 50 watts, Edison base; 500 Packard lamps, 25 c.-p., 110 volts, 78 watts, Edison base; 500 rosettes, with extra heavy lugs, for cleat work; 500 rosettes, with extra heavy lugs, for moulding work; 3,000 porcelain cleats, 2-wire; 1,000 hard rubber bushings for Edison sockets; 1,000 wooden socket handles, hard wood and polished; 1,000 cord adjusters, 100 attachment plugs to fit Edison sockets; 1,000 key sockets, polished brass, Edison type; 300 keyless sockets, polished brass, Edison type; 100 keyless wall sockets, Edison type; 50 pounds Grimshaw tape, black, ¾-inch wide; 30 pounds pure rubber tape; three gross shade holders, 3¼ inches, Gleason clamp; 1,000 white porcelain deep shades, 10 inches in diameter, for 3¼ inch holder; 4,000 pairs incandescent arc light carbons, ⅝-inch diameter (upper carbon to be cored and the lower solid); 50 gallons "P. & B." paint; 50 cut-outs, No. 61,465 of General Electric Catalogue, No. 7,503; 30 cut-outs, No. 61,487 of General Electric Catalogue, No. 7,503; 12 cut-outs, No. 61,243 of General Electric Catalogue, No. 7,503; 25 cut-outs, No. 62,835 of General Electric Catalogue, No. 7,503; 3,000 yards lamp cord, No. 18 B. & S. gauge, to have a seamless rubber insulation and an outer covering of cotton; 10 pounds Shawmut fuse wire, 1-ampere; 10 pounds Shawmut fuse wire, 10-ampere; 10 pounds Shawmut fuse wire, 20-ampere; 10 pounds Shawmut fuse wire, 50-ampere; 10 pounds Shawmut fuse wire, 75-ampere; 20 pounds Shawmut fuse ribbon, 100-ampere; 20 pounds Shawmut fuse ribbon, 150-ampere; 20 pounds Shawmut fuse ribbon, 200-ampere; 20 pounds Shawmut fuse ribbon, 250-ampere; 200 fuse links, 10-ampere, 1⅝ inches from center to center; 300 fuse links, 20-ampere, 1⅝ inches from center to center, 300 fuse links, 30-ampere, 1⅝ inches from center to center; 200 fuse links, 50-ampere, 1⅝ inches from center to center; 100 fuse links, 100-ampere, 4½ inches from center to center; 100 fuse links, 150-ampere, 4½ inches from center to center; 50 fuse links, 200-ampere, 4½ inches from center to center; 10,000 feet fire and moisture-proof wire, No. 12 B. & S. gauge; 5,000 feet fire and moisture-proof wire, No. 10 B. & S. gauge; 1,000 feet fire and moisture-proof wire, No. 8 B. & S. gauge; 5,000 feet fire and moisture-proof wire, No. 6 B. & S. gauge.

The last four items are to have two braids of underwriters' insulation and an outer covering of moisture-proof insulation to withstand a temperature test of 250° F., without impairment to insulation test. The wire to be delivered on reels containing 1,000 feet each. The reels will not be paid for by the Government, but will be returned to the contractor at his expense. 10,000 feet rubber wire, No. 12 B. & S. gauge; 5,000 feet rubber wire, No. 10, B. & S. gauge; 1,000 feet rubber wire, No. 8 B. & S. gauge; 5,000 feet rubber wire, No. 6 B. & S. gauge.

The last four items are to have a seamless rubber insulation and an outer covering of both tape and braid. Bidders must state guarantee as to action of acid fumes, acid solutions and alkalies upon the insulation; also what guarantee in rise of temperature above the surrounding atmosphere such wire will stand without impairing the insulation test and durability of the covering. Insulation resistance must not be less than 1,200 megohms per mile. Conductivity of copper to be not less than 98 per cent. A certified guarantee of wire for three years must accompany each proposal. The wire to be delivered on reels containing 1,000 feet each. The reels will not be paid for by the Government, but will be returned to the contractor at his expense.

LE ROY'S PORTABLE X-RAY APPARATUS.

The enormous aid which the X-ray apparatus can render to the physician and surgeon is now so well recognized that there can be no question as to the place which this valuable aid will occupy in the equipment of the medical fraternity.

Mr. J. A. Le Roy, of 143 East Thirteenth street, New York, has undertaken to place in the hands of the physician, as well as the scientific amateur, a complete X-ray outfit, consisting of coil, tube and fluoroscope, which is perfect in every respect. The coil is made specially for the tube, so that it can not perforate or destroy it, and the accompanying batteries are also exactly designed for the coil. Either bichromate or storage batteries are employed. The outfit is large enough to cover a shadow picture on an 8 x 10 or 10 x 12 plate .

The fluoroscope made by Mr. Le Roy consists of a tungstate of calcium screen, but, instead of spreading the salt on cardboard, Mr. Le Roy uses a sheet of aluminum of No. 30 gauge. This screen, Mr. Le Roy claims, has four times the fluorescing power of a cardboard screen, and gives a far sharper detail and clearer outline. Mr. Le Roy also makes fluorescing screens of special sizes with or without the fluoroscope attachment.

CROOKES TUBES.

Although the General Electric Company commenced very early in the present year to experiment on the making of Crookes tubes for producing Röntgen rays, it is only after a long series of careful observations that the company has decided that it was ready to put Crookes tubes on the market. As will be seen in our advertising columns, the Edison Decorative and Miniature Lamp Department is now ready to supply Crookes tubes of approved sizes and types. We are informed that very successful results have been obtained with the tubes already furnished by them. Experiments are being continued, in order that tne most improved forms may be within reach of the public constantly.

THE KEYSTONE SOCKET COMPANY has been incorporated at Wilmington, Del., by G. King, E. Shilling, and J. M. Davidson, with a capital stock of $100,000.

WESTERN TELEPHONE CONSTRUCTION CO.

The new Richmond (Va.) Telephone Exchange is the largest plant thus far started in opposition to the Bell Company. The apparatus for this exchange, to the number of 2,000 telephones and switchboard capacity, is being supplied by the Western Telephone Construction Company of Chicago. The new multiple switchboard being furnished to Richmond is the latest improvement in modern telephony. Mr. Keelyn, who designed the system, states that for large exchange work these switchboards will be the most rapid and effective of anything heretofore known. He says that no more movements are required to reach any subscriber in the system than are required with the Western No. 1, for small exchanges, which is claimed to be the most rapid and effective switchboard yet put into practice. The Richmond contract is 25 per cent. larger than any heretofore closed by the independent telephone companies for apparatus.

CALCIUM CARBIDE.

We are informed by "Progressive Age" that the very large extra edition of that journal for April 15, containing the Houston, Kennelly and Kinnicutt reports on carbide of calcium and acetylene gas, was exhausted within forty-eight hours after the appearance of that number. The publishers immediately prepared a second edition of 20,000 copies, which is now ready for those interested in reading the reports of these experts, which can only be found in full in "Progressive Age," the leading gas journal of this city.

NEW YORK NOTES.

THE ELECTRIC ARC LIGHT COMPANY, INCORPORATED, who make the Pioneer inclosed arc lamps, have removed to 687-689 Broadway, where they will have increased facilities for handling their trade.

MAURICE SICHEL has been appointed receiver for Frederick C. Timpson, dealer in electrical supplies, formerly at No. 143 Liberty street, on the application of the Electric Engineering and Supply Company, of Syracuse.

THE H. P. BALL MANUFACTURING COMPANY, of Brooklyn, has been organized to manufacture electrical appliances with a capital stock of $20,000. The directors are John E. Ball, C. B. Keough and M. A. Vosburgh, of Brooklyn.

MR. LOUIS J. HIRT, of the engineering staff of the Metropolitan Traction Company, after some very heavy work the past winter, particularly in putting the Lenox avenue conduit line in good working order, has taken a European trip, leaving by the City of New York on April 15. He will be gone several weeks.

D. VAN NOSTRAND COMPANY, Murray and Warren streets, New York City, have issued a new classified catalogue of electrical books, the chief feature of which is the careful and excellent arrangements by subjects. The list is very comprehensive and correct, and gives evidence of the enterprise of this old concern, whose other lines of scientific literature are not less extensive.

THE PHŒNIX INTERIOR TELEPHONE CO., who for the past year have conducted an extensive business in the manufacture of battery telephones at 131 Liberty street, will on May 1 remove their works to much larger quarters at 108 Greenwich street. In addition to their factory the company will open a large store on the ground floor of the Liberty Building, corner of Liberty and Greenwich streets, where they will carry a full line of electrical supplies.

NEW ENGLAND NOTES.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., have the contract to furnish the New Britain Knitting Company the steel work for their new boiler plant. The roofs of the buildings will have steel trusses throughout, and in designing these buildings everything has been so constructed as to render them thoroughly fireproof.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY have issued circular No. 20 (Catalogue, No. 146) devoted to "Current Practice in Protecting Electrical Apparatus Against Lightning." The article is by Mr. A. J. Wurts, and is, of course, an admirable exposition of the subject. It is supplemented by a number of interesting reports from central station managers all over the country.

PHILADELPHIA NOTES.

THE C. C. CLARK COMPANY has been incorporated under the laws of New Jersey, with a capital stock of $50,000 to construct steam and electrical plant. The headquarters will be in Philadelphia.

THE HUNTERDON ELECTRIC COMPANY, of Lambertville, N. J., have recently purchased a 100-h. p. Ball engine from the Parker Engineering Company, Philadelphia representatives of the Ball Engine Company, of Erie, Pa.

MR. CHARLES WIRT, 1028 Filbert street, Philadelphia, has enlarged quarters and increased facilities for the manufacture of the Wirt dynamo brush. Mr. Wirt reports that he has been making radical changes in methods of manufacture, as the old methods were too slow to keep pace with increasing business and too expensive to meet competition. The Wirt brush of to-day is being modified to suit different classes of machines, as it has been proved that the best combination of material for one case, is not the best for every case.

THE CUTTER ELECTRICAL AND MANUFACTURING CO. have just sent us their new catalogue of C-S. flush switches and accessories. It is the handsomest switch catalogue that has yet been printed, the numerous cuts shown being printed in photographic brown, with the letterpress in an attractive shade of green. Full details are shown as to the interior construction of the switch, and plans for wiring are also given. The switches have so long been before the public that an indorsement is unnecessary, but a short list of some of the users is printed on the last page of the catalogue, and these names bear out their claim that the C-S. switches are the standard for high-grade work. The catalogue is very artistically bound in heavy artists' paper, attractively printed in red and black. Ten thousand are now ready for distribution and will be sent upon application.

WESTERN NOTES.

THE HARTLEY ELECTRICAL WORKS, of Chicago, have removed from their old stand at 373 Dearborn street to much more commodious and lightsome premises at 263 Randolph street.

MR. WELLS GOODHUE has recently returned from a trip amongst his numerous customers, and is pleased to become acquainted with the smoke and dust of the Windy City once more.

WEST CHICAGO PARKS.—The specifications for the West Chicago Parks electric light plant will be ready for distribution on Thursday, April 23, and copies can be procured from Mr. Forée Bain, electrical engineer, 1657 The Monadnock. Bids will be opened on Tuesday, May 12, at the office in Union Park.

MR. E. P. ROBERTS has been appointed by Messrs. Yost & Packard, architects, as consulting engineer for the electric light and power and steam heating, and also the hydraulic and sanitary engineering, for the new Ohio State Asylum for the Insane, at Massillon, O., a very large institution, built on the cottage principle.

ELECTRIC APPLIANCE COMPANY.—As summer approaches the fan motor business awakes from a winter's slumber. The Electric Appliance Company already have quite a large stock of Meston alternating current fan motors, and are ready to do business in this specialty. Anticipation of requirements is always a good policy in placing orders for seasonable goods of this kind, and the Electric Appliance Company suggest that orders be placed as early as possible for the season's demands.

MR. JOHN F. OUTWATER, representing Hugo Reisinger, 38 Beaver street, New York, in passing through Chicago on his way home last week, made a pleasant call at the office of The Electrical Engineer. Mr. Outwater made a long and extensive business trip, and is quite pleased with the results. He was fortunate enough to escape the winter snows while on his journey, as he worked from the far Southern States to the Pacific coast, and now strikes his native soil at the brightest of all seasons.

CROOKES TUBES can now be purchased from the Sunbeam Incandescent Lamp Company, Chicago. This company has been experimenting continuously since the first announcement of the results obtained by Professor Röntgen and claims in its "Sunbeam X-ray Tube," as it is called, that the rays are brought together and in consequence a photograph can be produced that shows much sharper outlines. Also with this tube, the time of exposure is reduced. The Sunbeam tubes have been sold to several colleges where they have been pronounced superior to other American tubes.

Department News Items will be found in advertising pages.

SUPPLEMENT TO

THE

Electrical Engineer.

Vol. XXI. APRIL 22, 1896. No. 416.

THE GENERAL ELECTRIC REPORT.

WE give below a very full synopsis of the annual report of the General Electric Company. It shows sales of about $12,730,000 of apparatus. The deficit is somewhat cut down, but the profit and loss still stands nearly $14,000,000, and the patent and franchise account is put at $8,000,000, although any value above one or two millions must certainly seem problematical. The company would appear to be worth about 40 cents on the dollar.

FOURTH ANNUAL REPORT OF THE GENERAL ELECTRIC CO.

BELOW is given the annual report of Mr. C. A. Coffin, president of the General Electric Co., under date of Jan. 31, and issued from Schenectady under date of April 18:

In their last report, your directors referred at some length to the liquidation of old assets, and stated that the sum of $2,000,000 had been charged to profit and loss, for the purpose of providing for all shrinkages which could then be anticipated in the liquidation of old matters.

Much has been accomplished in the year just closed in liquidating old and slow assets, and the condition of the assets of like character which still remain on the books of the company is such as to enable your officers to more definitely fix their proper values. Information regarding these matters will be found in the report of the second vice-president, to which particular attention is invited. There have been charged against the $2,000,000 item above referred to the sum of $530,152.16, representing the shrinkages which have accrued from the liquidation so far as completed, leaving $1,469,847.84 still standing to provide for possible shrinkages in the future. It is the belief of your directors that this amount is sufficient to cover all the purposes for which the above sum of $2,000,000 was originally set apart.

The business secured by your company for the fiscal year just closed was less than ten per cent. greater in value of sales than for the year previous. The actual increase in output of factories, based upon capacity of machines and number of articles produced, is more than thirty per cent. greater than for the previous year. While the selling prices as thus shown have been materially reduced, there has been a corresponding curtailment in manufacturing and other expenses and lowering in costs, largely due to improved designs and methods of manufacture.

As will be seen by the statement of profit and loss, the business of the year just closed including royalties, amounted to..		$13,315,667.12
Cost of goods sold, plus legal, patent, and general expenses and taxes, was		11,759,857.08
		$1,555,810.04
Less interest on debentures in excess of interest and dividends received	$16,459.40	
Sundry losses................	27,178.31	
Depreciation on inventories and consignments........	123,204.87	166,842.58
Leaving		$1,388,967.46
There is charged off, in writing down factory plants, patents, etc., the sum of		511,321.97
Leaving net..............................		$877,645.49

Sales Department.—Attention is called to the report of the first vice-president, covering the operation of this department. From this report it will be seen that more than 90 per cent. of all the sales for the year were on the basis of cash within sixty days from shipment. The organization of this department is most excellent and effective, and the total expenses of selling and distributing the products of your factories during the past year have been materially less than for any previous year.

Manufacturing and Engineering.—By referring to the report of the third vice-president, in charge of manufacturing, much information will be gained as to that important branch of your business. Your directors are fully alive to the necessity of maintaining in this department the highest possible standard of economy and efficiency and they believe that the results so far attained in this direction are of the greatest value and importance. The achievements of your company in notable installations, involving the highest class of engineering and mechanical skill, have been especially gratifying.

Arrangement with the Westinghouse Company.—Since the close of the fiscal year a contract has been concluded with the Westinghouse Electric and Manufacturing Company, which embodies a recognition of the patents of each company by the other and the right, subject to certain exclusions, to a joint use thereof. An official notification of this contract was given out on March 13, and since then details necessary to make the arrangement effective have been concluded. It is believed that many advantages will be derived from this contract, specially in eliminating much costly litigation, and in the important relations of co-operation in engineering and manufacturing methods.

Patent Litigation.—The suits on the Van Depoele electric railway patents have progressed practically to a conclusion. In one case—that against the Elmira and Horseheads Railway Company—the United States Court of Appeals for the Second Circuit has rendered a decision finally sustaining the patent involved in that suit, and giving it a construction which brings within its scope the standard devices universally used for switching electric cars having an overhead trolley. In this suit were also sustained other claims of substantial importance.

In the suit against the Winchester Avenue Railroad Company, the Circuit Court of the United States for the Second Circuit has sustained the main Van Depoele trolley patent, giving it a construction which brings within its scope the standard overhead trolley cars in general use. These decisions are regarded as of great importance, and we believe that the above named patents having now been established by the courts will prove of substantial value to the company.

Suits on other patents in the railway and lighting field are pending, and are being actively pushed; some of these will come to a hearing during the coming year.

A number of valuable patents have been acquired by the company during the past year.

General Conditions.—The prices of your company's products have undergone excessive shrinkages in the adverse conditions of the past three years, and the securities held by it in local companies which were constructed upon the high prices of the past depreciated in like degree during the panic of 1893 and in the year subsequent thereto. Greatly modified valuations of your various assets have thereby been made necessary from time to time, and much information relating thereto has been brought to your attention in former reports.

It is believed that the necessity of further reduction of aggregate values will not arise, nor is it expected that the market prices of your products can suffer any substantial decline in the early future. The local enterprises in which your company is interested as a creditor or security holder are, as a rule, returning to normal conditions. Many of them give promise of greatly increased prosperity.

Similarly the inventories and other investments of your company are in such shape as to lead your directors to anticipate no shrinkage therein, beyond that for which provision has been made. In the mean time the varied applications of electricity are increasing and the output of the company's works should be augmented as a result of the added uses to which electrical apparatus is almost daily being put.

It will be noticed by referring to the Profit and Loss Statement that the revenue derived by your company from interest and dividends for the past year was nearly sufficient to provide for the interest on its outstanding debentures.

Capt. Eugene Griffin, as first vice-president, submits a statement of the operations of the sales department, for the year ending Jan. 31, showing a total of $12,730,058, made to over 10,000 customers, on a total number of 104,000 separate orders, or about 350 a day. Besides the regular supply business, which includes 9,000 separate articles, as well as renewals, the company sold nearly 12,000 complete machines, of a total of 500,000 horse-power. These figures include over 8,800 street railway motors, and 90,000 horse-power of railway generators. They were supplemented by nearly 6,000,000 incandescent lamps and more than 27,000 meters.

Over 93 per cent. of the sales provided for cash within sixty days. Only three-tenths of 1 per cent. provided for payment in stocks, bonds or exchanged apparatus.

Capt. Griffin's report refers in detail to new openings for goods and current, such as heavy railroad work, conduit roads,

phase power transmission, rotary converters, mill and mining plants, and the use of electricity in the chemical arts, such as the process of making calcium carbide, electric smelting, making bleach powder, etc.

Mr. E. W. Rice, Jr., as third vice-president, supplements these figures by those of an engineering character, and states that the improvements in the factory plants have increased the capacity 25 per cent. in the year. The generator and motor output in kilowatts was 380,000 or 509,000 horse-power, an increase of over 35 per cent., as compared with 1895. During the year the company have supplied, or had on order, 60,000 horse-power for apparatus for water power conversion and transmission. They built also some 30 generators of 1,000 horse-power and over, as well as some very large transformers, one for the Carborundum Company reaching 1,112 horse-power. The company protected their inventions by filing 92 applications for patents and by securing 92 patents issued to their engineers and assigned.

The report of Mr. J. P. Ord, second vice-president, is a very voluminous document, covering the financial details of operation and furnishing the company's balance sheet. It appears that the company commuted on all claims accruing under the patents and agreements with C. J. Van Depoele and J. C. Henry, and also made a full settlement with Mr. Edison of all claims under his contracts. It is also stated that the company owns seventy acres of real estate, with a total floor space in its three factories of 1,350,000 square feet. All are free from mortgage or lien. It has not been necessary to borrow money, nor has the company's credit been used for issuing notes, indorsing customers' paper for discount, or in lending their name to allied companies. There are no notes of the company out, and all purchases during the year have been paid for in cash. The average cash balance during the year has been $578,000. During the year the company has sold securities of a par value of $1,359,820 and carried as worth $514,053, for $707,399. It also sold the Schuyler factory.

The business of the year shows Gross Earnings $13,315,667, and Gross Expenses $11,910,240. Against this is a deduction

of interest due on debentures of $437,500, offset by $421,040 interest and dividends received on securities owned, leaving an amount of $16,459 to come off the gross earnings. Deduction is made also of amounts written off as follows: Patents and franchises, $159,264; factory plants, $322,339; other real estate, $29,718, making $511,321, and leaving a net of $877,645 as the reduction of the deficit of previous years.

The consolidated balance sheet for Jan. 31, 1896, is appended. It shows, as will be seen, nearly $14,000,000 under the head of profit and loss and patents and franchises carried at $8,000,000.

THE

Electrical Engineer.

Vol. XXI. APRIL 29, 1896. No. 417.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS ?—X.

BY

Wm. Baxter Jr.

Saving in Operating Expenses of Pennsylvania Railroad by the Substitution of Electricity for Steam.

IN what has preceded, the various items on the cost of operating trunk line railroads that can be reduced by the adoption of electricity, have been discussed, and in some cases the percentage of saving that could be effected has been shown. It is far more satisfactory, however, to know what the sum total of all these savings amounts to, and this point we now propose to consider. The Pennsylvania road has been selected for this comparison, not because it offers any unusual opportunities for making a good showing for electricity, but simply because the reports of this road are given more in detail than those of any other reports that we have been able to obtain. In order to be able to make a comprehensive comparison it is necessary to analyze the different items of expenditures and show the relation between them in the two systems. This can be better accomplished with the Pennsylvania Railroad reports than with any other.

Table 13 gives the operating expenses of this road for the year 1894. On inspection of the various items of expenditure it will be seen that the following are those in which a saving can be effected by electricity, as has been shown in previous paragraphs:

1. Repairs of roadway. 2. Removals of ties. 3. Repairs of bridges and culverts. 4. Repairs and renewals of locomotives. 5. Shop machinery, tools, etc. 6. Wages of enginemen and firemen. 7. Fuel for locomotives. 8. Water supply for locomotives. 9. All other supplies for locomotives. 10. Wages of switchmen, flagmen and watchmen. 11. Expenses of telegraph, including train dispatcher and operators.

The sum of all these items that can be reduced more or less by the adoption of electricity amounts to $17,205,624.18, which is nearly 42 per cent. of the total expenses.

To further assist in determining the extent to which the items which are composed mainly of wages can be reduced, Table 14 is given. In this table not only the salary, but also the number of employés of each class is given.

Referring to Table 13, it will be seen that the cost of keeping the roadway in repair is very great. When this item and the cost of new ties are added together we find that they amount to nearly ten times the cost of new rails. Now, as already shown, the effect of the unbalanced condition of a locomotive upon the track is very great, as it shakes it sidewise and up and down. This action loosens the ballast around the ties and also works the spikes and bolts loose. The locomotives are not the cause of all the wear and tear on the roadway, but they certainly cause a very large portion of it. That this item in the expense account could be considerably reduced by using electric motors there can be no doubt. An electric motor is a perfectly balanced machine, and all the wear due to the vertical and lateral motion imparted to the track by locomotives would be done away with. That the saving would be a large percentage will be evident when we notice the small expenditure for rails compared to the cost of renewing ties and keeping the road in repair. I believe that practice would show that these two items could be reduced at least twenty per cent. The repairs to bridges could also be reduced, and probably to the same extent. Bridge engineers are well aware of the fact that the deterioration of such structures is greatly increased by vibration. It is also well known that the vibration caused by locomotives is very much greater than that caused by an equal weight of cars; in fact, it would not be unreasonable to claim that it is three or four times as great. It is difficult,. however, to form any very definite idea of the saving in cost of repairs to these structures by the removal of the excessive strain brought to bear on them by locomotives, because no information is at hand as to the relative proportion of iron, wood and masonry that enters into their construction. The class of work that deteriorates most under the stress of jars produced by the moving load is the iron. Woodwork

*Fuel for locomotives	3,724,481.14
*Water supply for locomotives	264,840.81
*All other supplies for locomotives	236,616.84
Wages of other trainmen	4,341,318.10
All other train supplies	821,684.79
*Wages of switchmen, flagmen and watchmen	1,017,118.72
*Expenses of telegraph, including train dispatchers and operators	1,142,946.05
Wages of station agents, clerks and laborers	4,614,006.31
Station supplies	574,260.24
Car mileage balance	1,046,678.39
Loss and damage	245,650.89
Injuries to persons	198,180.15
Barges, floats, ferryboats, expenses of, including coal, wages and supplies	753,407.63
Other expenses	678,266.82
Taxes	381,741.55
Total	$22,755,190.89
General Expenses.	
This includes salaries of officers, clerks, agents, etc., office expenses, advertising, insurance, legal expenses, etc., and amounts to	$2,941,199.98
Recapitulation of Expenses.	
Maintenance of Way and Structures	$6,713,305.07
Maintenance of Equipment	8,594,104.26
Conducting Transportation	22,755,190.89
General Expenses	2,941,199.98
Grand total	$41,003,800.20

Number of locomotives on Pennsylvania Road :

Passenger	478
Freight	1,103
Switching	224
Total	1,805

New locomotives added during the year : Passenger, 9 ; switching, 2.

comes next, while the effect on stone structures is so slight as to amount to nothing practically. In all probability the repairs on bridges and other girder work could be reduced ten per cent. by the use of electric motors and the consequent reduction in vibration, but a conservative estimate would probably place the figure as low as five per cent.

The next item in the line of repairs is that of locomotives, and it is the most important of all, not only because it amounts to a very large sum, but also because it is vastly greater than the corresponding expenditures in an electrically operated road could possibly be. In order to more fully show its importance it will be well to make a comparison with the cost bill, and also the relative proportion that each one constitutes of the total expenses. In this way we find that it is equal to something over 78 per cent. of the entire cost of fuel consumed by locomotives. We also find that it amounts to over seven per cent. of the total expenses of operating the road, while the fuel bill only exceeds it by two per cent.

In most all of the calculations that electrical engineers have made on the subject of substituting electricity for steam on trunk line railroads, the main effort has been to show that a great saving could be made in cost, and that this gain would be enough to render the adoption of the system desirable from a financial standpoint. But here we see that we have an item nearly as large as the

coal and one which, from the very nature of things, can be reduced enormously by the substitution of electric motors for locomotives. In order to show that the claims here made are not unreasonable it will be well to quote one of the best authorities on the subject of steam locomotives, Mr. Arthur Wellington. In speaking of the cost of locomotive repairs and their apportionment to the various parts, he gives the following figures: Boiler, 20 per cent.; running gear, 20 per cent.; machinery, 30 per cent.; lagging of boiler and painting, 12 per cent.; smokebox, etc., 5 per cent.; tender, 13 per cent.

Looking over these figures we see at once that some of them would disappear completely in an estimate of the repairs of electric motors, because those parts are not used with the latter, nor is there anything to take their place. Those parts that would be struck out would be: Boiler repairs, 20 per cent.; running gear, 20 per cent.; lagging and painting, 12 per cent.; smokebox, etc., 5 per cent.; tender, 13 per cent., making a total of 70 per cent. of the entire cost of repairs to locomotives. It may be claimed that to strike out the repairs of running gear is not proper, as this part of the machine is used with electric motors as well as in locomotives, but if the motors are placed on the trucks of a car, then the only increase in cost of repairs on such trucks would be the cost of keeping up the motors, and this, therefore, is the only charge that can be justly made against the motor, as the expense of maintaining the trucks would be the same whether motors were used or not.

NEWS AND NOTES.

CONTEMPORARY ELECTRICAL SCIENCE.

The management of electrical waves is making rapid progress. Herr von Lang, "Wiedemann's Annalen," describes Quincke's familiar apparatus for showing the interference of sound waves through two branches of a tube of unequal length, except that electric waves are substituted for sound waves. As the length of one of the branches is varied, distinct maxima and minima are shown by the "coherer" employed for their detection. Filling one of the branches with another dielectric such as paraffin or sulphur enables the observer to determine the velocity of the waves in those substances, and hence their refractive indices. They come out rather higher than usual.—L. Zehnder gives one more rule for the directions and signs of the various occurrences in the electromagnetic field. It is perfectly general and very simple in form, but its appl cation seems to require profound study.—Joseph von Gietler examines the wave systems given out by the more complicated forms of Hertz generators. He finds that for every length of the secondary circuit the primary circuit emits several wave circuits of different thicknesses and intensities. He determines these intensities by means of resonators.—W. Holtz recalls that in 1889 he found that conductors were more opaque to the electric glow discharge than dielectrics. This result was at the time so "absurd" that he began to doubt it himself. It has now been made very probable by Röntgen's discoveries. Herr Holtz calls upon physicists to make further experiments in this direction, being himself prevented by illness from doing so.

DR. LODGE'S EXPERIMENTS IN ROENTGEN RAYS.

Dr. Oliver Lodge puts it on record in the "Times" that during the past ten days he has seen fluorescence excited by Röntgen rays after they had penetrated the bodies of two men, standing one behind the other, in their clothes. Also he and his co-workers have succeeded in radiographing the details of a damaged vertebra in the spine of an adult patient at the Northern Hospital, Liverpool, with an exposure of half an hour, and found a "Murphy-button" in the intestine of another adult at the Liverpool Royal Infirmary with an exposure of ten minutes. A focus tube and a powerful ordinary induction coil were the means used.

ROENTGEN RAYS AT THE ACADEMIE DES SCIENCES.

The "Comptes Rendus" for March contains no fewer than twelve communications relating to X-rays. M. A. Lafay describes the following experiment: Underneath a Crookes tube, about ½ centimetre from the most brilliant portion, he ar ranged a leaden screen pierced by a slit 2 millimetres wide. Some 4 centimetres lower he placed a second lead screen pierced by a 5-millimetre slit, completely closed by a very thin strip of silver foil supporting a platinum wire 1.5 millimetres in diameter, exactly in the axis of the slit. The silver foil was connected to the negative pole of the induction coil. The rays then passed between the poles of an electromagnet, capable of generating a field of 400 C. G. S. units, the lines being parallel to the slit. In the first experiment M. Lafay, with a sensitive plate, 8 centimetres away from the poles of the electromagnet, obtained no certain trace of deflection. With the plate 15 centimetres off, however, there were unmistakable evidences of deflection of the rays in the same direction as would be the case with cathode rays.

QUAKERTON, PA.—Mr. Gottlieb Frey, the city electrician and superintendent of the electric light department of the borough of Quakerton, Pa., informs us that a company is being organized there to construct and operate a telephone and fire alarm system. He is himself interested, and will do all he can to promote this needed improvement.

THE VOLTA ELECTRIC COMPANY, of New York City, has been formed with a capital stock of $10,000. The directors are Paul A. Curtis, E. W. Curtis, and John Potts.

ERIE CANAL.—It is rumored that $2,000,000 foreign capital has been offered for the right of operating on the Erie Canal by electric traction.

CANTON, MISS.—Mr. E. A. Stimson, superintendent, reports that contractors are at work on an extensive system of water works and electric lights. The old central station is being enlarged, and Canton will soon rank with the best towns in the State in water and electrical service.

ELECTRIC LIGHTING.

HIGH VOLTAGE LAMPS AND THEIR INFLUENCE IN CENTRAL STATION PRACTICE.—III.

BY G. E. ADDENBROOKE, M. I. E. E.

IT is generally acknowledged that in the three-wire system at 110 volts it is not economical or very practical to distribute current at a radius of much more than three-quarters of a mile from the central station, except under special circumstances. The area which can therefore be economically served from such a station is about one and a half miles each way, or about two and a quarter square miles. In his well-known feeder paper Mr. Crompton gave figures which he argued showed that a feeder on the three-wire system supplying 110-volt lamps could be laid and maintained, and would involve the same loss of energy, taken over the same day, as would an alternating feeder, including transformers, instruments, and switching gear, the length of the feeders in each case being 2,400 yards. These figures were strongly attacked by the alternating party, myself amongst the number; the most legitimate point of attack being that Mr. Crompton had assumed a loss of 30 per cent. at full load on the low-pressure feeder, which was considered excessive on account of the extra plant it would entail at the central station. Had Mr. Crompton put the length of his feeder at about 1,400 yards, or a little over three-quarters of a mile, and had he used a density of about 500 amperes per square inch—which is about the practical density—the loss would have been 16 per cent. for the continuous current feeder at full load, and few alternating men would have seriously combated that on the whole the continuous-current feeder was as economical and desirable as an alternating feeder. The figures would then agree with the generally current comparison which I have mentioned above, and which I propose to use as a basis of argument in order to avoid disputes.

Now, from data I have collected, it appears that in such places as the center of large towns there are perhaps 30,000 inhabitants per square mile, though ordinarily the population for a square mile of a town does not appear to exceed 16,000. A low-pressure station on the three-wire system with 110-volt lamps can therefore serve economically about 60,000 to 70,000 people in the centers of large towns, and about 35,000 in districts outside the centers and in provincial towns. If, therefore, we wished to light London, with its 4,000,000 population, on this basis, taking the average population at 25,000 per square mile, we should need, roughly, 70 to 80 stations to light the whole metropolis, not counting the extreme suburbs.

If, however, in the direct supply system the voltage is double, the position is altogether altered, and a comparison between the transformer and direct supply systems under these circumstances will lead to very different results from those so far given. Theoretically, if 220-volt lamps are used, we can extend the feeders four times as far as if 110-volt lamps are employed, and therefore the area which could be lighted from each station is 16 times as large. I do not intend to take full advantage of this facility in the calculations which I propose to lay before you, as I consider that the fall of voltage is too large in low-pressure central stations at present, and that the voltage of the lamps at different points of the distributing system is not kept as near the normal as it should be. In what I am about to say I shall therefore consider that, instead of four times, we extend our feeders a little over three times as far as before, thus securing better regulation and a smaller percentage drop in both the feeders and distributing system, together with the great saving in copper. If, then, we can extend the lighting radius three-quarters of a mile from a low-pressure direct supply station with 110-volt lamps, we can extend it, on the above basis, 2½ miles at 220 volts, which means that we can cover an area of 5 × 5, or nearly 25 square miles from one station—that is, 11 times the area we could before. Instead, therefore, of serving 60,000 people in the central districts, one central station would serve 700,000, and over a quarter of a million in the less central districts. Taking, then, the population of London as 4,000,000 without extreme suburbs about six or seven stations would comfortably cover the whole area. Now this is a number which is directly comparable with the number of stations at present being operated by the gas companies; and to my mind it is doubtful if it would be desirable to reduce the number of stations below this figure for so large an area, even if it could be managed.

It would be interesting to go into this metropolitan lighting problem further did time permit, but it does not, and I must ask you now to turn your attention to the provinces. Take maps of Birmingham, Liverpool, Glasgow and Manchester, and cut out a piece of tracing paper to represent 25 square miles on the same scale as the map. Lay the tracing paper over these maps, and you will find that two stations, or at most three, will cover not only the whole of these great cities, but the suburbs for a couple of miles outside. For the general run of large towns one station would amply suffice; and for the smaller ones one station would, of course, permit of lighting over the whole area at a very small expense for mains. Before a technical audience like this, however, it will doubtless be more satisfactory to investigate a particular instance than to proceed further with general statements.

At 220 volts pressure an ampere represents 220 watts; therefore, one-third ampere represents 73.3 watts. Now at 4 watts per candle power a 16-c.-p. lamp takes 16 × 4 = 64 watts, and an 8-c.-p. lamp 32 watts. We shall therefore be sufficiently near for the purposes of this calculation, and shall be allowing a sufficient margin, if we assume that a 16-candle lamp takes one-third ampere, and an 8-candle lamp one-sixth ampere at 220 volts.

Next consider the distributive system. There are two points needing attention: the first is, How far, and over what area, can we spread our network from the feeder points? The second is, What drop should we allow on the feeders themselves?

But before going into these matters further we must settle what shall be our greatest drop from the feeder point to our furthest lamp on the network spreading from it. The variations which are permitted at present are too great, and would have to be reduced in time anyhow. I therefore do not intend to adopt the present practice as a basis, but to take as the limit an extreme fall of 2 per cent. on the distributing system from the feeder point to the furthest lamp at the tops of the houses; that is, lamps near the feeder would be 1 per cent. above their proper voltage at full load, and extreme lamps 1 per cent. below. This is, I think, as large a variation as good practice would allow, though it is less than half what is considered permissible now. Having settled this, the following data and table will enable us to see at a glance the best method of designing the mains and their cost.

1. A bar of copper 1 in. in section and 1 mile long weighs approximately 9 tons, and its resistance is $^1/_{22}$ of an ohm, or 0.045.

2. Therefore a double conductor 1 mile long and 1 in. in section weighs 18 tons, and its resistance is $^1/_{11}$ of an ohm, or 0.090.

3. I do not think it will be necessary on the high-voltage system to have the third wire in a three-wire system more than one-fifth the section of the other two, except, perhaps, in the distributing system. In fact, I understand Mr. Crompton considers the third wire could be done away with altogether as soon as the feeder gets a good load joined up to it, so that only the distributing system would need the third wire, these wires being joined together at the distributing point.

Consequently, the weight of a set of mains on the three-wire system—the two outers 1 in. section, and the inner one-fifth of an inch—would be 20 tons per mile; and the cost for copper at 6½d. per pound, would be £1,210 in the mile of mains. Now at 1,000 amperes per square inch a main this size would carry current for 6,000 16-c.-p. lamps, if perfectly balanced on the above basis, and the fall of pressure would be 90 volts in the mile, or 17 per cent. Such a fall of potential as 17 per cent. in the mile is excessive, and therefore we must arrange to work at a smaller current-density.

To enable the best current-density to be judged I have arranged the following Table I.:

TABLE I.

DATA RELATING TO FEEDERS ON THREE-WIRE SYSTEM SUPPLYING 220-VOLT LAMPS—$^1/_3$ AMPERE PER 16-C. P. AND $^1/_6$ AMPERE PER 8-C. P. LAMP.

Current density in amperes per sq. in.	Loss in volts per mile of double conductor.	Percentage fall of potential at full load.	Kilowatts available per sq. in. section of outers = 2.2 sq. in. copper.	Number of lamps carried by mains 1 sq. in. section = 2.2 sq. in. copper.		Cost per mile of copper at 6½d. per lb.			
						Per lamp alight at once.		Per lamp installed = twice lamps alight.	
				16 c. p.	8 c. p.	16 c.p.	8 c.p.	16 c.p.	8 c.p.
		%				s. d.	s. d.	s. d.	s. d.
1,000	90.0	17.0	440	6,000	12,000	4 0	2 0	2 0	1 0
500	45.0	9.3	220	3,000	6,000	8 0	4 0	4 0	2 0
400	36.0	7.6	176	2,400	4,800	10 0	5 0	5 0	2 6
300	27.0	5.8	132	1,800	3,600	13 5	6 8	6 0	3 4
250	22.5	4.86	110	1,500	3,000	16 0	8 0	8 0	4 0
200	18.0	3.85	88	1,200	2,400	20 0	10 0	10 0	5 0

This table enables us to see the reduction in fall of potential which we get by reducing the current for a given section, and

also the cost for copper which will be incurred for such density per mile run.

Now it is not unusual in some low-pressure central stations to have falls of even more than 16 per cent. at full load on the longest feeder; but this is an undesirably great fall, save on exceptional occasions, such as Christmas week, or during a fog in winter, and I think, with the immense reduction in copper cost which the use of high-voltage lamps gives, it is desirable to work with smaller falls. Suppose we accept 250 amperes per square inch as a basis, it will be seen that mains on the three-wire system will cost us 16s. per 16-c.-p. lamp alight at once, and 8s. per 8-c.-p. lamp per mile, and the drop of potential will nearly be 5 per cent. Now, if we assume that current is supplied 2½ miles from the stations as an extreme, as we did before, our longest feeders will be about this length, the drop at full load on the feeder will be about 12 per cent., and the cost of copper 40s. per 16-c.-p. lamp, and 20s. per 8-c.-p. lamp alight at once for the longest feeder.

If we take the network as proceeding from the feeder points at the same current-density—namely, 250 amperes per square inch—and if we agree that it shall extend rather over a quarter of a mile from the feeder point, to allow for irregularities, so that each feeder will feed a network covering half a mile square, it will be noted that the drop, including extra lengths of main for going round angles and into the houses, will be about 1½ per cent., and the extreme cost of copper per lamp alight at one time in the network will hardly be more than 4s. per 16-c.-p. lamp, and 2s. for an 8-c.-p. lamp, while the mean cost will be about three-fourths of this, and the mean drop of potential only 1 per cent.—and even this can readily be reduced by a little judicious adjustment.

We therefore see that for feeders extending about 2¼ miles, and a network extending a quarter of a mile further from the feeding point—that is, 2½ miles altogether—the extreme cost for copper per 16-c.-p. lamp lighted at once will be about 44s., and for an 8 c.-p. lamp under 22s.

This represents extreme lengths. The average length of feeders to cover the above area would hardly be more than 1¾ miles, or three-fourths of the above maxima, and the cost of the copper, on the average, in the distributing system will be reduced in like proportion. We shall therefore be correct in taking three-fourths of the above sums as the average cost of copper per lamp lighted at once from station to lamp, including both feeder and network, in a station covering a town area of equal density 25 square miles in area. This is, approximately: Per 16-c.-p. lamp, 33s.; per 8-c.-p. lamp, 16s. 6d. Further, from practice and the tables in "Lightning," we know that there are usually at least twice as many lamps installed as are required alight at once; therefore we may put the capital cost of mains for copper once at about: Per lamp installed —cost of copper, 16-c.-p., 16s.; 8-c.-p., 8s.·3d.

Now it is fair to take 6 per cent. per annum as the sum to allow for interest and depreciation on the copper in the mains —say 3½ per cent. for interest, and 2½ per cent. for depreciation. At this rate, on the above capital cost, the annual cost for interest and upkeep comes out at under 1 shilling per 16 c.-p. lamp, and 6d. per 8 c.-p. lamp installed.

Further, on looking through the tables of consumption of current, it will be found that 18 units per 8-candle lamp installed is a fair all-round average—at least, it is the average from "Lightning" for London and most of the provincial stations. At this rate, therefore, it will be seen that the upkeep and interest on capital for the copper in the distributing system comes to 0.33d., or one-third of a penny per unit of current sold; or, supposing the sum actually received for current is 6d. per unit, the cost for interest and upkeep on the copper in the distributing system represents less than 6 per cent. of the cost of current. Out of this cost it will be noticed that about three-fourths of the copper is in the feeders and one-fourth in the distributing system.

X-RAY PICTURES WITHOUT PHOTOGRAPHY.

Righi describes, in "L'Electricien," an apparatus by which he obtains the Röntgen pictures without the use of the photographic plate by a method similar to that employed by Lichtenberg and Kundt. Under the Crookes tube is fixed a sheet of black cardboard, backed by a sheet of aluminum, which is connected to earth. Below this is fixed a sheet of ebonite, backed with tinfoil, which latter is connected through an air condenser to the cathode of the tube. The anode of the tube is also put to earth. If a hand is now laid on the cardboard, and subjected for a sufficient time to the action of the tube, it will be found that an electrical picture of the hand à la Röntgen has been imprinted on the sheet of ebonite. This can be made visible by the well-known mixture of sulphur and red lead, or by another mixture of talc and dioxide of magnesium, which gives an effect more closely resembling a photograph. The bones, etc., are shown in these electrographs just the same as in the Röntgen photographs.

ROENTGEN RAYS.[1]

BY PROF. HENRY MORTON.

In connection with Dr. Röntgen's discovery and the X-rays, there are a number of facts long known which in some cases seem to be forgotten, and which, while in no way detracting from the originality and merit of his discovery, yet need to be considered in order that the true characteristics of this discovery should be recognized, and the mixed or uncertain character of many experiments recently made by others in attempting to repeat or extend his results, clearly appreciated.

Thus to begin with, it is not new that invisible radiations obtained by electrical discharges in Geissler tubes and elsewhere, should produce photographic and fluorescent effects. In the "American Journal of Art and Science," 1864, vol. 37, p. 207, will be found a paper by Prof. O. N. Rood, of Columbia College, entitled "On the Action of Very Weak Electric Light on the Iodized Plate." From this paper I will make a few quotations:

"About three years ago Dove received from Mr. Gunther, of Berlin, a photograph of a bronze statue of an Amazon holding a lance in a perpendicular position, Mr. G. at the same time calling his attention to a singular mark in the picture, which was not in the original."

"The lance was properly delineated on the negative plate, but in addition just at the tip, a dark streak was visible, though nothing of the kind had been observed at the time of taking the picture. Careful examination of the plate showed two other analogous marks. Dove thought that these singular appearances might have been caused by the presence of invisible electric brushes, resting on these points, and undertook some experiments to determine whether weak electric light could be photographed. Geisler tubes were used in a dark room and with the aid of Gunther he succeeded in obtaining good photographs of the stratified discharge."

Professor Rood then goes on to describe further experiments of his own, made to ascertain if these faint electric lights or discharges could be photographed in a light room and when they were invisible to the eye. After describing some preliminary trials he further says: "Accordingly, to make an exact experiment on this point, a sheet of white paper was placed behind one of these" (Geissler) "tubes and white light reflected through it towards the camera. The intensity of this reflection was so regulated that the bright envelope of platinum wire" (in the tube) "was nearly invisible, and the diffused violet light at a greater distance from the wire, absolutely invisible. Nevertheless an intense photographic image of the envelope, and a very distinct image of the diffused electric light was easily obtained, thus proving conclusively the correctness of Dove's assumption that electric light, which in ordinary daylight could not be seen, owing to its feeble illuminating power, might yet make itself very evident on the iodized plate, by virtue of its high percentage of chemical rays."

The above is interesting as showing that as early as 1864 the relatively greater photographic than visual effect of the light produced in exhausted tubes (Geissler tubes) was recognized.

About the same time and thereafter, and indeed up to the present day, much work has been done in photographing that part of the solar spectrum which represents those vibrations which by reason of their short wave-length have either little effect upon the eye or none at all.

Prof. Wm. A. Miller[2] in London carried this work far enough to show that he could, by the use of quartz lenses and prisms, secure a photographic spectrum from the electric light extending beyond the visible violet for a distance several times as great as separated the extreme violet from the lowest visible red, at the other end of the visible spectrum. It was thus shown that invisible radiations of short wave-length possessed remarkable photographic power.

I will now turn to another line of observation which marks a limitation or distinction of the Röntgen effects in another direction. When the eye is directed towards a faintly luminous object it will either at once perceive it (under favorable conditions) or not at all. In other words, nothing will be gained by continually gazing at it. On the contrary, the best chance of catching sight of a faint object, such as a feebly luminous comet, is to look away from the true direction and then, with some quickness, to turn the eyes towards it. In this way we can often secure a momentary impression of a dim object which we cannot perceive continuously. With the sensitive photographic plate, however, all this is reversed. An amount of light which, acting on a plate for one second, pro-

[1] From the "Stevens Indicator."

[2] See "Phil. Trans." of Royal Society, 1862.

duces no sensible impression will produce a strong one if its action is continued for twenty or thirty seconds, and so on up to several hours of exposure. One of the most interesting illustrations of this has been furnished in connection with the photographing of stars carried on at the Harvard Observatory, under the Henry Draper Memorial, maintained by Mrs. Henry Draper, of New York; but the first observation of this phenomenon was made by Mr. A. A. Common, of England, in connection with his beautiful photograph of the nebula in Orion. It was there found that, besides the impressions of visible stars on plates exposed for a long time, there were many other similar spots or images occurring time after time, in the same positions on successive plates, which were due to stars too faint to be perceived by the eye, but yet capable, by prolonged action, of producing images on the sensitive plates.

We see, then, that the photographic plate has yet another means of seeing in the dark, besides that due to its power of perceiving vibrations whose wave-length is too short to affect the nerves of the retina. By its accumulative action or capacity of storing up the effects of any sort of vibrations capable of affecting it, rays too feeble to affect the eye will, in time, impress the sensitive film.

There is yet another region of observation which should be marked off in order to appreciate fully the nature of the Röntgen discovery. When in August of 1880, Dr. A. G. Bell announced his remarkable invention of the photophone, by means of which sounds and articulate speech could be conveyed from one place to another by a pencil of light, he stated at the same time that the radiant vibrations of sunlight by which this result was secured were only to a moderate extent impeded by a sheet of hard rubber thick enough to shut out to the eye every trace of light even from the concentrated rays of the sun.

It had also been noticed some time ago by others that a sheet of hard rubber was not a perfect shield for a sensitive plate if there was any considerable exposure to sunlight. (See also Photography of the Infra-red region of the Solar Spectrum. W. H. Pickering, Ph. D., "Pro. Am. Acad. of Arts and Sciences," 1864.) Moreover, Carey Lea, of Philadelphia, more than twenty-five years ago showed that a negative plate could be so acted upon as to develop an image, on applying the usual developer, by the application of very moderate heat and even of slight mechanical pressure. (See his Manual of Photograhy, 2d Edition, 1871, p. 408.)This last is of special interest in connection with Tesla's recent suggestion that the Röntgen pictures may be due to the mechanical action of the impact of particles actually driven at high velocities from the cathode pole.

While the above facts detract nothing from the originality and merit of Dr. Röntgen's real discovery, they are of use in helping us to appreciate what is its important and central characteristic and to discriminate between the same and many of the so-called repetitions and extensions of his work with which the daily papers have been filled. The Röntgen discovery differs from all that went before, not in the broad fact that some sorts of radiation would act on sensitive plates when by passing through certain screens or otherwise they had become or were invisible, but in that this investigator has shown a new sort of vibrations absolutely devoid of luminous properties and yet capable of easily penetrating certain materials of the greatest optical opacity, such as black paper.

The experimenters who have been producing shadow photographs with sunlight, electric lights, and the like have not been repeating Röntgen's operations, but only applying facts known for fifteen or more years. There is another part of Röntgen's work which, though followed up by some, has as yet excited much less general attention, partly no doubt because the materials and conditions for making experiments are less easy to secure, and also because the results are not permanent, but must be inspected while they are being produced. I allude to the developments of fluorescence and the production of shadow pictures visible on a fluorescent screen.

To make this subject clear, and, as before, to bring out the exact novelty of Röntgen's work in this connection also, I must go into the early history of the subject of fluorescence. This was first systematically studied by Professor Stokes, of Cambridge, England, and admirably developed in his classical paper in the "Philosophical Transactions" for 1852, Part 2, p. 466, et seq. In this place he shows that quite a number of solid bodies and solutions possess the power of absorbing light vibrations of various wave-lengths and then instantly emitting them again, but always with an increase of wave-length. Thus, for example, a solution of acid sulphate of quinine will absorb the extreme violet rays of the spectrum, and then emit them as bright blue rays. Again, an alcoholic solution of chlorophyl (the coloring matter of plants) will absorb yellow rays, as well as shorter ones, and emit red light. There are many other bodies acting on and producing different rays, but in every case the emitted ray is of greater wave-length, or as we may say, lower in the spectrum than the absorbed or exciting ray.

As might naturally be expected on this principle, the extremely short wave-lengths of rays above the visible violet of the spectrum causes them to be absorbed by most fluorescent bodies, and emitted as rays of greater wave-length and therefore visible, and thus in this way, also, was supplied a method of making invisible light of solar vibrations visible. In fact, Stokes showed that if a solar spectrum was thrown on a block of "canary glass" (glass colored greenish yellow by oxide of uranium) its upper end was elongated or rendered visible by the fluorescent light developed, just as it was similarly extended upward when photographed upon a sensitive plate.

Besides canary glass many other materials could be used, the most efficient being a sheet of paper coated with a paint made from finely pulverized crystals of the platino-cyanide of barium. This subject was further investigated in this special relation by Stokes and also by Miller in 1862. (See Phil. Trans., 1862.) In 1872 the present writer had the good fortune to discover in and extract from certain dense and tarry petroleum distillates a hydrocarbon to which he gave the name Thallene, which possessed this property of fluorescence in a pre-eminent degree. Itself of a light lemon-yellow color if spread as a pigment on paper, it shines out with a flood of grass-green light when placed in an invisible part of the spectrum or when there fell upon it violet or blue light. Its peculiar properties were exhibited at a lecture on Fluorescence, delivered in the Academy of Music, in Philadelphia, in 1872, in the following manner:

A screen or curtain, about twenty feet square, of muslin of the yellow color of Thallene, was prepared, and to this was attached a design of leaves, wreathes, etc., made of paper coated with Thallene. Seen by gaslight this design could not even be recognized at a short distance, but when the rays of a powerful electric light, sifted through a dark purple glass which cut off all but the violet and super-violet radiations, were thrown on it the design fairly blazed out in vivid green on a background of muslin, which looked as dark as black velvet. The yellow muslin could not reflect any of even the violet light, but the Thallene turned this, as well as the super-violet invisible rays, into green light. A full account of this material will be found, among other publications, in "The Chemical News," of London, 1872, vol. 2, p. 272; The London and Edinburgh "Philosophical Magazine," 1873, vol. 45, p. 89, and the "American Chemist," 1873, vol. 3, pp, 81 and 162. The general subject of "fluorescence" is also discussed at some length by the present writer in the article under this heading in Johnson's American Encyclopædia.

Here, then, we see, that prior to Röntgen's experiments, it was well known that certain practically invisible rays could produce visible effects through the action of "fluorescence." What Röntgen has added to this is the knowledge that such rays are developed in peculiar abundance in the highly exhausted tubes known as "Crookes Tubes," and that they will penetrate with unexpected facility a great many optically opaque substances. Just what is the distinguishing character of these peculiarly actinic and fluorescogenic rays is at present a problem enshrouded in great obscurity, by reason of the conflicting statements of experimenters.

Röntgen and others say that they proceed from the cathode terminal. Professor Rowland and others say that they come from the anode. Tesla thinks that they are not vibrations of any sort, but are streams of projected material particles.

It would seem that the judicious course is to build no theories, but to extend experiments and accumulate facts. This is being done by various able and experienced investigators who have not been in haste to publish the incomplete results of their work. Among these we would refer to Prof. O. N. Rood, of Columbia College, New York, and Prof. A. M. Mayer, of the Stevens Institute of Technology, New Jersey. Among their interesting results is an absolute demonstration that the X-rays are incapable of polarization. This property was indicated by Professor Röntgen in his original publication, but not positively established, and is of great importance as radically distinguishing the new radiation from any known variety of heat, light or actinic vibrations.

HOW WIDELY THE "ENGINEER" CIRCULATES.

It may be of interest to you to know that we have received an inquiry for bi-metallic wire from Catanzaro, Italy, the writer having seen our advertisement in The Electrical Engineer.

BI-METALLIC ELECTRIC TRANSMISSION CO.
New York City, April 16, 1896.

RECENT DEVELOPMENTS IN VACUUM TUBE LIGHTING.[1]

BY D. MC FARLAN MOORE.

MOST people have been accustomed to oil lamps, gas jets and other forms of light which have about reached their perfection. With the appearance of the arc and incandescent lamps it was thought that electricity had reached its limit in giving to the world a system of illumination that would leave nothing more to be desired. Indeed, it seems almost a presumption to dare to think of light being produced that would approach daylight in form and quality. The time is not so very remote when any man who would have attempted to

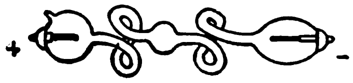

FIG. 1.

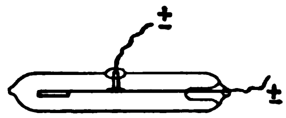

FIG. 2.

manufacture sunshine would have shared the fate of a Galileo.

But fortunately the investigator of to-day has nothing of this kind to fear. Much arduous labor has already been expended in the solution of the problem by many eminent electrical scientists engaged in the study of vacuum tube phenomena, but the results from a practical point of view have been very meager. This is chiefly owing to the complicated and expensive apparatus necessary, and the very unsatisfactory results even then obtainable. In fact, light from vacuum tubes, which is the only form of illumination that actually approaches nature's standard—daylight, has never been obtained in any quantity that would, in any way, be suitable for practical use. Of the other forms of electric lighting, the incandescent lamp is the most prominent. It is the peer of all

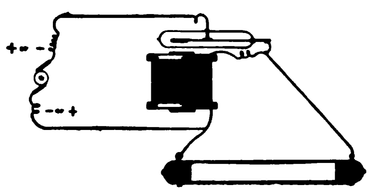

FIG. 3.

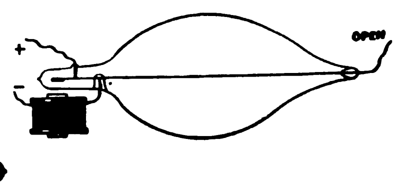

FIG. 4.

illuminants in commercial use to-day, but is lacking, when we consider maximum uniformity in the distribution of light, and when calculations show that only three-tenths of 1 per cent. of the energy of the coal necessary to produce light by incandescence (its name defines its character) is actually transformed into light, it is evident that there is room for improvement. The new electric light should possess all the good qualities of the present lamp with none of its drawbacks, and among its improvements will be noted the combination of utility and decoration. The recognized tendency of the day is toward multiplication of lights and avoidance of strong shadows—in other words, an even illumination, that is, light from all directions.

The object of this paper is not only to call attention to the advantages that will accrue with the adoption of vacuum tube lighting, but more particularly to a simple method of obtaining a current which will ultimately make such an

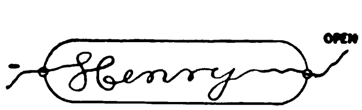

FIG. 5.

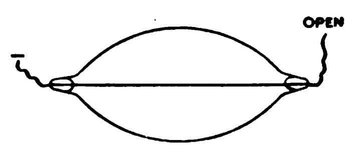

FIG. 6.

adoption universally feasible. Almost without exception, experimenters in vacuum tube lighting have hitherto sought for the solution of the proмem by merely pushing to extreme well-established methods based on principles long known in the art. That is, strictly speaking, no radical departures from the well-beaten paths have been as yet brought forward. However, this paper does represent radical departures: in principles, in apparatus and in the nature of the current, resulting in a light of greatly increased intensity.

[1] Read at the meeting of the Am. Inst. Elec. Engrs. April 22, 1896.

Before entering upon a description of the new system, permit me to call your attention to the methods heretofore used for obtaining light from hermetically sealed glass tubes containing a rarefied gas.

For many years the Geissler tube has been a scientific toy. When a suitable electric current is connected to its terminals, its entire length is filled with a faint glow. This is, of course, a light of radically different character from that now used in any commercial form of illumination. (See Fig. 1.)

It is light emanating from rarefied air with an apparent absence of heat and combustion. Upon this principle developed, probably depends the light of the future, which will soon be, in the opinion of the writer, the "light of the present." As a device for transforming electrical energy into light, the vacuum tube is very efficient. The majority of authorities place it at about 70 per cent. and the incandescent lamp at 2 per cent. Notwithstanding this remarkable efficiency, it has never been commercially possible to illuminate by vacuum tubes, because the light could not be made sufficiently intense (this is expressing it mildly) even with bulky apparatus that was entirely impracticable.

Furthermore, the current produced by such apparatus was of such a nature as to render its insulation extremely difficult. The ordinary induction coil is often used for this purpose. A current of low voltage, such as that from a battery of a few cells, must be used with such a coil, because a current of higher voltage could not be properly disrupted, the arc forming preventing a sudden break of the current. But since the light depends on the suddenness of the break, the arc must be prevented, therefore the quicker the break, the brighter the light—provided the apparatus is properly designed.

The quickest break can be made by interposing in a circuit the most perfect dielectric in the minimum space of time. The best dielectric known is a vacuum, and I have discovered methods for interposing it in rapid succession in a current in a minimum space of time, depending upon the principle of making and breaking a current rapidly in a vacuum.

The disruption of any current in the air results in the formation of a spark of greater of less length, and the greater its length, the less sudden the break. Therefore, if the break be made in a vacuum, the narrowest conceivable complete gap in the metallic conductor results in an almost instantaneous discontinuance of current, insuring a maximum e. e. m. f. The current is thus interrupted in an almost infinitely short space of time as compared with all the ingenious mechanical contrivances, such as air-blasts and magnetic blow-outs devised for the purpose of breaking a current suddenly in the open air, but all of which are of little avail for the production of any quantity of light.

The vacuum vibrator, as shown in Fig. 2, is the nucleus of my invention. Although an exceedingly small device (not as large as one's finger) it demonstrates when in circuit with a small magnet (not as large as a teacup), a principle embodying great possibilities. It is a new piece of apparatus, exemplifying a principle of value not only applicable in practical use, but also an improved implement for scientific investigation.

It is almost unnecessary to describe such a simple piece of apparatus, which consists merely of a spring rigidly supported at one end, and having attached to its free end a small disc of soft iron. A contact point rests against the spring at about its center. A sealed glass tube, from which the air is exhausted, incloses both spring and contact point. The system, as a whole, is exceedingly simple. An electric current passes through a coil of wire and then through the vacuum vibrator. Wires in contact with the outside of each of the ends of a

closed and empty glass tube are attached to the two ends of the coil of wire. This statement embodies the gist of the invention. (Fig. 3.) It will be noticed that this system is far simpler than the apparatus ordinarily used to excite Geissler tubes. The secondary coil is absent, reducing the expense and bulk manyfold, as are also the metallic terminals sealed into the ends of the Geissler tube, but it produces light, the desideratum, in wonderfully increased volume.

With this apparatus, currents of almost any voltage can be rapidly and suddenly interrupted, and it is therefore now possible to obtain by using ordinary commercial currents, strong light in vacuum tubes.

When the circuit through the magnet and vibrator is closed,

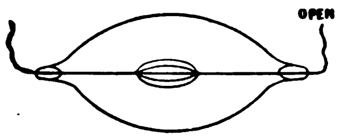

FIG. 7.

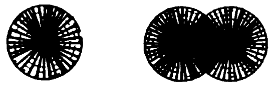

FIG. 8.

the armature within the vacuum vibrates rapidly, disrupting the current within the vacuum at each vibration.

The resulting high tension current excites a brilliant luminosity in another tube, usually of much larger dimensions, and containing a lower vacuum than the vibrator tube. There is, therefore, a necessity for two vacuums, one the very highest, the other very low. However, I have tried a number of experiments, using but one vacuum, practically amounting to an enlargement of the vibrator tube and a lowering of its vacuum. (See Fig. 4.)

This is manifestly not a good plan for the production of light, because the breaking of the current does not occur in a high vacuum, but it led to an interesting line of experiments, the most novel of which will now be brought to your attention.

Within this low vacuum is placed a wire which can be bent

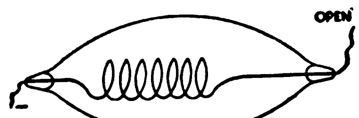

FIG. 9.

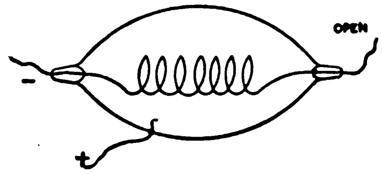

FIG. 10.

and shaped into any form desired, as shown in Fig. 5. When connected to the vibrator, the beautiful effect is immediately apparent, the wire being enveloped in a delicate purple glow. This can be applied to various purposes, such as advertising. One wire only connects this sign tube to the vibrator, and it is attached to the armature terminal of the vibrator, because when so connected, it is the one which receives the high potential discharge of the magnet. In the bulb now shown (Fig. 6), the vacuum is higher, and a single wire extends through the center. The light, instead of appearing as a purple envelope around the wire, now fills the entire chamber with a beautiful milky glow.

Close inspection, however, reveals the fact that there is a very small dark space immediately encircling the wire, and beyond it there appear to be rapidly moving rings of light, concentric with it. In fact, one is reminded of the field of

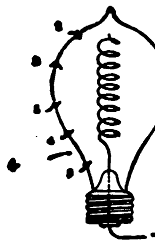

FIG. 11.

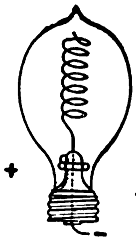

FIG. 12.

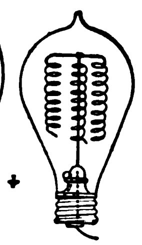

FIG. 13.

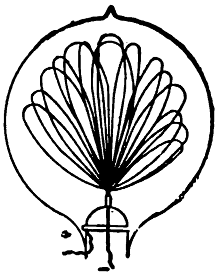

FIG. 14.

force surrounding a conductor, as displayed by the familiar arrangement of iron filings—indeed, it is a similar phenomenon—the molecules of the residual gas taking the place of the iron filings.

The next bulb (Fig. 7) is similar to the one last shown, but with one exception. The wire is not single throughout its entire length; for a space of about three inches at its center it separates into six strands, which thereby form a kind of cylindrical cage about one-half inch in diameter. In this case the entire bulb is not filled with a glow, but the interior of the cylinder forms a pencil of light quite dense, denoting that a new principle is brought into play. It is this—every current creates its own electrostatic field around its conductor, which, when immersed in a gas at the proper degree of rarefaction, causes it to give forth light, which is most dense in a comparatively small circle surrounding the conductor. (Fig. 8.)

When two wires, each having its field of force, are placed parallel to each other and about one-half inch apart, the density of the field between them will be doubled, and con-

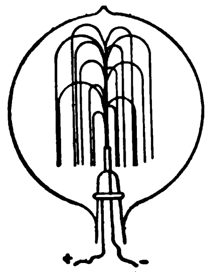

FIG. 15.

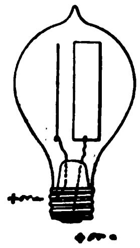

FIG. 16.

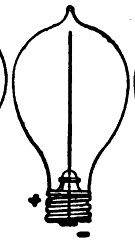

FIG. 17.

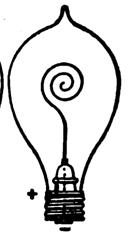

FIG. 18.

sequently the light in almost the same proportion. It will thus be clear that the pencil of light is due to the intersecting or overlapping of the fields of force of each of the six strands forming the cage. Upon this new principle many interesting lamps have been constructed, the problem being to get a maximum number of fields of force to intersect. Probably the best solution is in a cylinder made by spirally winding a wire, as in Fig. 9, causing its field to intersect in a manner that is almost ideal. This explanation may seem at variance with Faraday's famous experiment, proving that an electrostatic charge does not reside in the interior of the charged body. The vacuum may make the difference.

In this bulb (Fig. 10) there are two separate terminals projecting from the glass. When the spiral is connected to the negative pole of the vibrator, and the other terminal is made positive, the light is greatly increased. Such a lamp can be very conveniently made by using an incandescent lamp bulb, as in Fig. 11. The bit of platinum wire extending into the bulb and forming the positive pole, can be placed in any of the positions 1, 2, 3, 4, 5, without affecting the light in the spiral, but it is apt to become heated, and this is remedied by attaching to it a metal wire ring. (Fig. 12.)

In these lamps a large proportion of the light is confined within the spiral, and since volume is desirable, the idea of increasing the number of spirals suggests itself, as in Fig. 13. But the total volume of light emitted by four spirals is only equal to that of a single spiral lamp, that is, each pencil is but one-fourth as bright; hence, to bring them all to full brightness, the energy of the inductive current should be increased in proportion.

With the idea of obtaining from the entire bulb a uniform glow, the lamp shown in Fig. 14 was constructed. The "filament" consists of a great many complete loops of very fine aluminum wire. Fine wire was used, not only because of appearance and weight, but also for two other reasons: 1st, because a fine wire has about as large a field of force as a much larger wire; and, 2nd, because it does not obstruct the light so much, and at the same time is a minimum of metal within the vacuum. This is a matter of importance, as upon it largely depends the life of the lamp. A great many different conductors were used for the construction of these filaments, the main idea being to use that material which contained the least occluded gas, and would be disintegrated a minimum by the action of the current. Fig. 15 shows ordinary incandescent lamp filaments utilized in a glow lamp, but one leg only is cemented at the center of the bulb to the negative terminal, the other being free—a veritable fountain of filaments. A rather curious and not entirely explained phenomenon was noticed in this form of lamp, viz., the free ends of the filaments were apt to be violently agitated, and whenever they touched

the glass of the bulb, they heated up to a bright red throughout their entire length, producing a most brilliant combination glow and incandescent light. Many are the advantages of these lamps over those using fluorescent materials, as the sulphide of zinc or calcium. Sometimes when the exhaustion is carried a little too far, the vibrator current is unable to affect the lamps, but after they are held in contact with one pole of a large induction coil for a few moments, and then connected to the vibrator current, the trouble ceases.

In all of these forms of lamps it is very interesting to note that in order to get maximum light, the sub-divided terminal of the lamp must be so connected to the mains that it is negative. This is interesting to remember when the subject of lighting tubes is considered.

The class of lamps will now be considered where, instead of sub-dividing the lighting electrode into filaments, plane surfaces are used.

The bulb in Fig. 16 contains two pieces of sheet aluminum equal in size, set with their planes at right angles to each other, in order that a minimum of light may be interrupted from any point of view, and that the positive will act as a reflector to the negative. These pieces of aluminum must be carefully cleaned before being placed in the lamp, because any grease upon them will cause beautiful tufts of light all over their surfaces, instead of a glow filling the bulb, and the vacuum will soon be lost. Of course, in a lamp of this construction the poles can be changed with impunity, and if an alternating current be passed through the vibrator, both plates will give light, but the total amount will be the same as when direct current is used.

One of the many modifications of this form of lamp was to make the magnetic pole in the form of a small cylinder of aluminum gauze.

Many lamps were made on the principle of a spiral within a spiral, wound in the same or opposite directions, and also of using metallic coatings on the tube's interior and exterior, as well as using bulbs of all shapes and sizes. One important advantage to be noticed in all these forms of lamps is the total absence of the very objectionable striations, such as occur in the ordinary Geissler tube.

Fig. 17 is a very simple form of lamp—merely a single piece of straight carbon filament producing the light.

Fig. 18 is another of peculiar form—an unusual density of white light inside the convolutions of the spiral.

To determine whether there was any appreciable heat at the center of an intense pencil of light, a number of lamps were constructed in which various substances were placed at the point of greatest density of light, as in Fig. 19, but in no instance was the substance affected in any degree whatever.

Following out this idea a little further, there was inserted a small glass tube containing air properly rarefied in the center of a spiral, as in Fig. 20.

But the inside of the small tube remained dark; nevertheless, the glow outside of the spiral, dark space and other phenomena, even to the tufts of light between some of the convolutions of the spiral are the same as those in a similar lamp without a tube, inside the spiral.

Another lamp was then made the same as the last, except the tube inside the spiral has a platinum wire extending into it, which wire is electrically connected with the spiral (Fig. 21). Of course, the small tube was tried separately before being placed in the lamp bulb, and it filled with a white glow. But after the lamp was completed it refused to give any light; the glow outside the spiral, however, was the same as though there was no inner tube present.

Hoping to get a lamp with almost no metal in the light-producing vacuum, the lamp shown in Fig. 22 was constructed—the spiral is within a separate tube. When tried, a tuft of light appeared in the top and bottom of the small tube which was surrounded by a faint glow, the outlines of which are shown by the dotted line.

The next step was to do away with the inner vacuum and construct a bulb as shown in Fig. 23. When a spiral was inserted in the tube and connected to the negative pole, the positive being either 1 or 2, a dark space an eighth inch deep surrounds the tube, beyond which a faint pinkish glow appeared filling the bulb. The phenomenon known as "after-glow," which is sometimes noticed in evacuated bulbs after having been subjected to an electrostatic strain, I have been able to obtain, but very seldom. (Fig. 24.) However, this bulb could be picked up and carried around the room, but every time it was picked up after being laid down, a discharge resulted, which, being repeated three or four times, dissipated the glow entirely.

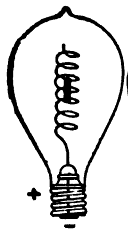

FIG. 19.

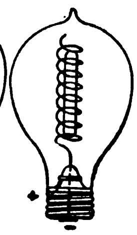

FIG. 20.

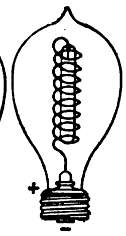

FIG. 21.

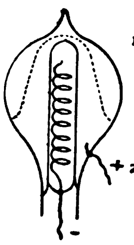

FIG. 22.

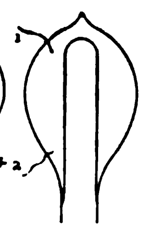

FIG. 23.

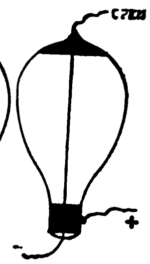

FIG. 24.

From a tube containing two parallel wires, shown in Fig. 25, but with a low degree of exhaustion, the glow was entirely absent, but instead brilliant, flaming yellow discharges completely filled the space between the wires, which was over half an inch wide and about two feet long.

At the beginning of the lecture your attention was called to the great similarity existing between the field of force of a "cold-light" giving conductor in a partial vacuum, and that of a conductor conveying a current in the open air. Care, however, should be taken to note that the light from the rarefied atmosphere is due to electrostatic and not electromagnetic phenomena.

For example, I have here a powerful electro-magnet which I connect directly across the lighting mains and, therefore, it is one at whose center or core the electro-magnetic field is very dense. When this tube, which has a diameter the same as that of the core of the magnet, has about half of its length passed through the center of the magnet, no light whatever results. If, however, but one terminal (the other being free) of this same magnet be connected to the vibrator, immediately the tube gives forth light.

Referring again to the subject of connections, Fig. 26 shows the light connected around the terminals of the magnet; it also can be connected with equal results around the break or spark gap as shown by the dotted lines. Your attention is called to the fact that lamps of this kind will operate equally well whether connected in multiple or in series, provided the area of the negative electrode is about the same in each; if not, that one in which the negative electrode is of greatest area will alone light up.

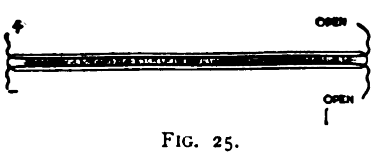

FIG. 25.

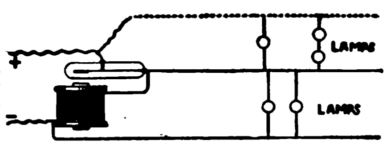

FIG. 26.

If a single bulb of small size be connected to a circuit of considerable induction, a well-defined discharge is liable to occur which will ruin the lamp.

In Fig. 27 an inductive resistance is distributed with each lamp, making the system of distribution self-regulating, that is, the turning on or off of lamps will not affect the brilliancy of those burning steadily.

Referring again to the diagram of circuits showing the system in its simplest form: If good results are to be obtained, the magnet must be designed and constructed with the greatest care. Its duties are twofold; first, to give the vibrator its mechanical motion, and second, to act as an inductive re-

sistance. The iron core must be proportioned to the conditions of the circuit. If there be too much or too little, the light suffers, but a certain amount of iron should remain, in order that the magnet have sufficient power to vibrate the armature. Similarly if there be too many or too few turns of wire on the magnet, the light is decreased. From this it is evident that vibrators of different rates will not be suitable to the same magnet. However, even when a vibrator is connected to a suitable magnet and circuit, and produces a good light, it can be further improved by "tuning the circuit," that is, altering its self-induction by varying the amount of iron in the magnet's core. It should also be stated that by this means a maximum light is obtained from a minimum current. In order that the time constant of the magnet be a minimum, and to insure rapid action, the magnets should be short and thick. Large induction coils cause the tubes or lamps to give forth but little light, while a small magnet, whose length of

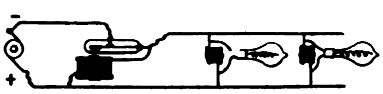

FIG. 27.

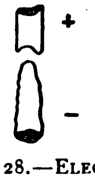

FIG. 28.—ELECTRIC LIGHT CARBON.

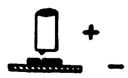

VIBRATOR CONTACT POINTS.

wire is not one-hundredth that of the induction coil, will cause the tubes and lamps to light up brilliantly.

It is interesting to note that with a comparatively few turns of wire a very small one-volt battery will give quite a strong glow. This glow can be intensified by using a secondary coil.

Although the various lamps that have been described are of great interest, nevertheless the very nature of lighting by luminescent gas is such that it is far more applicable to radiate from sources of considerable area than from units of light of small area. The best method of obtaining light from a large area is by the utilization of tubes of considerable length, instead of small bulbs. The light of these tubes should be entirely free from the very objectionable striations always present when interior electrodes are used; but these striations are entirely obviated by using exterior electrodes. They may be metal caps on the outside of the tube, or preferably merely coatings of metallic paint. Such tubes can be made up in almost any lengths, and can be bent into a great variety of forms, making them suitable for exquisite decorative effects.

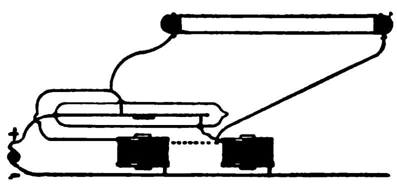

FIG. 29.

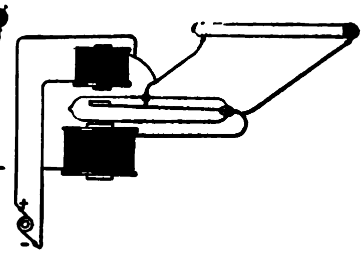

FIG. 30.

Under this head can be mentioned the fashioning of tubes in the form of letters, which may be used as electric signs.

Permit me to call your attention once more to the key of the whole system, viz., repeated interruptions of an electric current in a high vacuum.

The simplest method of accomplishing this object is to hermetically seal within a glass tube a vibrator of ordinary form, but its exact construction to give the best results has been a matter of tedious experimentation and study. The very slightest alteration in the dimensions of almost any of its parts—such as the length, width and thickness of the spring, or its method of mounting, or the position of the contact points, or the thickness or diameter of the amature, will cause it to be a very good or a very poor vibrator. Again, the operations of the glass-blower had to be watched most carefully. Only certain kinds of iron and steel were selected, to avoid occluded gases, and even then they must undergo a special treatment before being fit for use. The selection of suitable contact points has also been a large field for research. Nearly all known conductors have been tried, and many interesting facts have developed in this connection, not only so far as the direct action on the various metals in vacua and various gases is concerned (and this in several instances is the reverse of the phenomena noted in open air), but also with reference to the electro deposition or electrolytic action that takes place. For instance, as is well known, the positive electrode is the one which disintegrates most rapidly in the open air, and its apex is usually concave. This is probably best shown in the ordinary direct current arc lamps. If aluminum or any soft metal of comparatively low fusing point be used as contacts in a vibrator, after about a day's run, an examination shows that the shape and condition of the contacts are just the reverse of the way they appear after use in the open air. That is, the positive terminal looks like the negative, and the negative like the positive. (See Fig. 28.)

I have constructed several dozen distinct varieties or amplifi-

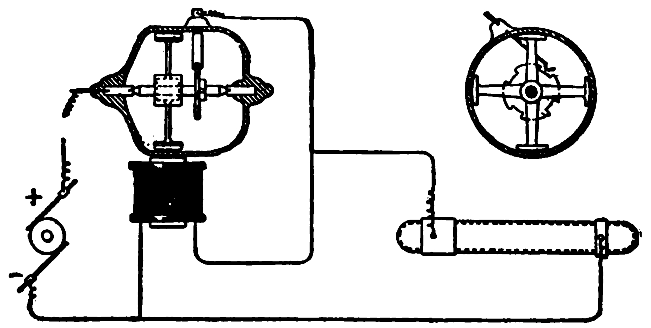

FIG. 31.

cations of the ordinary type of vibrator, such as multiple contacts, etc.

Fig. 29 shows one form, in which the object was to produce a larger number of breaks of the current per unit of time by providing two contacts, as shown. In some respects this scheme worked well, that is, the light was stronger than that produced by an ordinary vibrator with a single magnet, but the light was not steady, and when the connections were changed so that but one magnet was used, the light flickered still more. All the vibrators, so far considered, have had their springs so adjusted that the contacts remained normally closed. Fig. 30 shows a circuit using a vibrator normally open. The small magnet constantly closes the circuit and the large one opens it. This arrangement gave a good light. A number of ordinary vibrators have been operated, arranged with the magnet above the armature, so that gravity helps close the circuit. Of course, springs and armatures of scores of shapes and sizes, including gravity vibrators, have been tried, the principal object being to obtain a method for taking up the wear of the contact points; but the best solution of this problem lay in getting contact points that would not wear because of a more perfect vacuum.

Turning now from the mechanical construction of vacuum vibrators to consideration of their unique properties from a scientific standpoint. As stated before, roughly speaking, the prime object of making the break of the current in a vacuum is to produce an increased c. e. m. f. over that resulting from an airbreak. But I venture to say, few as yet realize the possibilities and the tremendous advantages involved in the separation of electrodes in high vacua at regular periods of time. It is indeed questionable whether the increased c. e. m. f. of the ether gap is responsible for the results. It is more probably due to the fact that the wave-lengths of the current resulting from an ether gap differ radically from any that have heretofore been known of. Recognition of the importance of this phenomenon led me to use the word "etheric" in connection with my system of tube lighting, because the light is directly dependent upon what I designate as the ether gap of the vacuum. Our best notion of the separate existence of the ether is formed by thinking of that which remains within a vacuum of the highest degree we can produce. It may have been noticed, that so far I have not used the word "phosphorescent." It is undoubtedly a misnomer as applied to tube lighting; but to make matters worse, there seems to be no word in existence exactly or even approximately suitable.

The word etheric is especially applicable to light produced by the ether gap. That incomparably better results should be obtained by using a vacuum as a dielectric seems to be in perfect accord with accepted theory which has largely been upheld by actual experimentation. For example, setting aside for the time being that part taken by the magnet, let us consider only the break—the spark.

First, what is required is a continuance of the rapid oscillations of an electric discharge, and I desire to show that this is accomplished by a vacuum vibrator in an ideal manner. One method of obtaining an oscillating discharge is to use a potential such that an air-gap of considerable width is bridged by the spark. But the manner in which such discharges succeed each other largely depends upon the irregular movement of the air within the gap.

This method is unsatisfactory for many other reasons, among them the very objectionable high tension required, but there remains the conductive method of causing a spark, exemplified in the ordinary vibrator and induction coil. Here the sparks in the primary circuit can be made to succeed each other quite rapidly, but the length of time required for each complete break is long. However, with the vacuum vibrator, a new and simple device, the conditions are different and so are the results. Here the dielectric is an exceedingly thin film of ether, which is capable of withstanding a great electrostatic strain, but when it does break down it does so very suddenly; that is, it may be considered a perfectly disruptive discharge, and therefore its single oscillations are very short; but as a whole they are long continued. This means that the frequency is high, and, according to Maxwell, very high frequency oscillations are probably identical with light.

The small magnet, being a circuit of induction, has its own natural period. But its period and moment of inertia will be less the less its capacity. That is, the smaller the magnet the smaller the period, or the higher its frequency can be.

But to have an intense light, there is required a high e. m. f. of self-induction. This the small magnet furnishes, because what is lost in self-induction by using a comparatively few turns of wire is more than made up by the suddenness of the discontinuance of current flow, and the fact that the high vacuum precludes the possibility of loss to the self-induction ordinarily due to the glow discharge which precedes the disruptive discharge in the air. The self-induction also depends on the amount of current flowing through a circuit when interrupted, and this the vibrator provides for, in that all the current which flows through the coil does not pass through an arc, but is transmitted over actual metal contacts. Also since these contacts are so very close, due to the thinness of the dielectric, the oscillatory discharges do not leave the metal and pass in objectionable minute streams through the vacuum. And the number of oscillations in the coil and the amount of light, depend in a measure on energy expended to overcome the resistance of the dielectric which is almost infinitely greater than that of air.

That the silent discharge prevents long continuance of oscillation is shown in the Hertz experiments, where the experiment fails unless the balls of the electrodes are kept polished. That the vacuum vibrator is nearly ideal is again shown in that these troubles are almost entirely eliminated. The ether is undoubtedly the ideal medium in which to disrupt an inductive circuit for conversion into light: since an exceedingly thin film (if this term may be so used) is a dielectric of such strength that a very small displacement results when it is disrupted, and the ether being the medium of minimum rigidity closes the "hole" the instant it is pierced. Such a medium for such a purpose is almost incomparable to air or oil, which becomes volatilized.

In order to get any oscillations, more sudden rushes of current must occur on discharging than on charging, and the more nearly these equal each other, the quicker the rushes will succeed each other. Now, in the case in question, when the tube circuit with its condenser coatings has a certain capacity, the self-induction of the magnet can be so varied that these two will always neutralize each other, and then the critical strain on the dielectric requires but little energy to cause a discharge, and the circuit being almost balanced, the surges follow each other in rapid succession through the tube. The surges continue for a longer time, since the energy of the discharge is not dissipated in heat on the air, but is conserved to be utilized in prolonging the existence of the oscillations. The use of this vibrator seems to afford the best means yet invented for impressing molecular disturbances in a tube. The longer the oscillations exist, the more nearly the mean oscillation approaches a constant period, and this period is practically governable as compared with that of currents due to magnetic blasts or heated air currents. The higher the frequency, the greater the mean free paths of the molecules, because a less number of molecules will then be required to cause a given number of collisions, and the less the number of impacts, the greater will be the light in proportion to the heat. But the frequency is dependent on the capacity of the condenser, which, in the case of the tube coatings, is very small.

When the self-induction and capacity are properly proportioned, and the rate of the vibrator is the same as the natural period of the coil, or any of its harmonics, then there is resonance, and the maximum amplitude of each impulse will be constant. In this case the current flow is at its maximum, but so also is the voltage at the ends of the tube, as well as the quantity of light produced with a minimum expenditure of energy. The velocity of the lines of force produced by an oscillatory discharge is supposed to be equal to that of light, but its wave-lengths are exceedingly greater. But this disparity is greatly reduced by the vacuum vibrator. This accounts for the intense light in the tube at comparatively low potentials, and indicates that nature's keyboard has been struck to the tune of 500 trillions of waves per second, and that this rate is maintained by the fundamental mechanical vibrations of the vibrator—about 100 per second—a most beautiful demonstration of nature's wonderful compass. But not only is more light produced by the vacuum vibrator than was heretofore obtainable, but there accompany it many other advantages of particular importance. Three of these can be mentioned: first, simplicity and greatly reduced cost of apparatus; second, the obviation of impracticable potential, and third, a very marked advance in economical production. The first heading, simplicity, has already been dwelt upon. Compare an inexpensive magnet, not as large as one's hand, and a vibrator the size of one's finger, attached to commercial currents, with apparatus costing thousands of dollars, consisting of a high speed alternating dynamo of many coils, oil transformers, disruptive discarges with magnetic blast, induction coils and condensers. The many seemingly unsurmountable difficulties encountered with this method are almost completely overcome by the simple expedient of the ether gap. Or, referring to ordinary induction coils, the vacuum break affords a means for obtaining from the few turns of comparatively coarse wire results not obtainable with mammoth and expensive coils, made of many miles of wire, and capable of creating enormous differences of potential.

The second heading is essentially a practical one. It has often been argued, to the detriment of tube lighting, that since it was admitted by its supporters that enormously high potentials were absolutely requisite to cause any appreciable amount of light, that therefore (and the argument was logical) the whole idea was extremely impracticable unless some new insulator be discovered that could cope with the high potentials, so difficult, dangerous and expensive of generation and manipulation, as to prohibit their use commercially. But with a current endowed with such properties as are given it by a vacuum tube vibrator, no new insulator is needed.

A light now results many times brighter than that formerly due to millions of volts, able to pierce several inches of hard rubber, or produce a spark many inches in length, from a current transmitted to the bulb or tube over ordinary flexible cord, and whose sparking distance is less than one-sixteenth of an inch. Neither can any shock be felt from such a current. Another example of the comparative ease with which this new current can be insulated is apparent in the magnets, wound in the ordinary manner, in striking contrast with the necessity for expensive and cumbersome oil transformers. In this light the exclusion of all gaseous matter does not seem to be a matter of such vital importance.

Closely allied with the subject of insulation is that of frequency. The higher the frequency, the lower the potential can be, not only with respect to light, but also to insulation, because irregularity in the rate of vibration puts the insulation to a severe test. However, the period of the vibrator is not rapid as compared to that of alternating dynamos, constructed to obtain similar lighting effects, but resulting in those of lesser degree. The alternations of such a machine are about 30,000 per second, which is further increased by a disruptive discharge coil. This was necessary to compensate for the long wave-lengths of the current. But since these lengths are so much shorter in the vacuum vibrator current, an initial frequency one-fifth as great without the use of additional coils and condensers produces far better results. But that an ordinarily constructed vibrator can attain a speed of 6,000 per minute may be questioned, when it is remembered that induction coil vibrators work at a rate of but little over 1,000. The difference lies in the fact that the vacuum vibrator has no air pressure to impede its movements, and also that a much shorter space of time is required for a single complete interruption, because the actual mechanical movement can be much less, yet cause a complete break, and another cycle has begun. The speed of the vibrators is ascertained in two ways: first, by comparing the musical note it produces with that of a pitch

pipe, and secondly, by a visual arrangement constructed and operated as follows:

A shaft, supporting a wheel with one spoke, is rotated rapidly by hand, a series of multiplying gears being used, so that when the hand makes one revolution per second, the spoke makes twenty. When this apparatus is operated in a room, lighted only by a single vacuum tube, the spoke will appear stationary in one, two or three positions, according to the rate of the vibrator. For example, if the spoke appears stationary in two positions, it indicates that it is illuminated twice in a single revolution, each image being due to a vibration.

Another subject, which has been a serious obstacle in former proposed systems, is that of impedance. The fact that the best conductors would cease to transmit current seemed a difficulty almost unsurmountable; yet it appears to be almost absent under these new conditions. For example, when a large coil is inserted in the high potential lead from the armature terminal to the tube, the effect on the light is surprisingly small. The result is the same, whether the wire be in the form of a magnet or in a long exposed line. But, nevertheless, on account of line losses, it is advantageous to prevent condenser action by using a wire as small as possible, yet able to stand the strain it is subjected to when its insulation is being placed upon it. Although the light produced by a single wire is quite good, it is decidedly advisable for best results to use a return wire, because the fundamental frequency is so low.

The third subject—economy—is so large, and of such importance that I deem it expedient to make it the subject of a future paper when accurate measurements have been made. Indeed, it is second only—but it is second—to the nucleus of the whole investigation, viz., getting light. The efficiency of the lighting tube is well established, due principally to the great amount of light accompanied by so little heat that it has by some been called "cold" light. The temperature of the gas within the tube varies with the density of the discharge from 12° to 132° C.; but even this is improved by the shorter wave-lengths. These figures are extremely low as compared with temperatures as high as 3,500° C., which must be reached by some substances in order that the light be white and the spectrum complete.

Owing to the peculiar characteristics of the current, the line losses are materially decreased, and the current flowing through the primary circuit is less when the tube is giving light than when it is disconnected. There are almost no losses for motive power to disrupt the current, for the magnet is its own motor. But the greatest loss has always been in the disruptive discharge—the spark. It is remarkable how easily several horse-power can be dissipated in the air through the intervention of a disruptive discharge. In this connection it should be borne in mind that magnetic blow-outs and air currents are merely heat dissipaters, and increase the loss, while these losses are entirely obviated by the vacuum vibrator. The current can perform a large amount of work on the air, unlimited in volume, with no apparent results; but when this volume is reduced to the campass of a small vibrator tube which remains perfectly cool in operation, does not the question of efficiency assume a different aspect?

Upon these reasons may be based logical conclusions, pointing to an enormous increase in efficiency over that of all other methods of obaining light in tubes.

The theory which has just been considered, of course, is not limited to a simple vibrator, but applies broadly to any method of interrupting the flow of current through a high vacuum. This can be accomplished in a great variety of ways, although as far as simplicity of apparatus is concerned, the regular spring vibrator, in connection with a single magnet, probably cannot be improved upon.

The first deviation, however, is to use a very small magnet to vibrate the armature, and to connect this in series with a larger one to furnish the induction. But in these cases the power of the operating magnet depends on the current passing over the contact points; hence to make the light which is dependent on the contact points perfectly positive, the power should not be dependent upon them, and separate circuits suggest themselves—that is, cause an intermittent current to flow through the power magnet that does not flow through the contact points of the vibrator, which have in circuit with them the inductive magnet. Or the electrodes can be separated by mechanical jarring instead of magnetic power acting through the glass.

If an ordinarily constructed vibrator be attached to any form of rapidly oscillating mechanism, the contacts within will be opened and closed rapidly. But in order that the light be steady, the movements of the vibrator armature must be in step with the movements of its mechanical support. This is best accomplished by having the center of the oscillation of the vibrating armature coincident with that of its oscillating support.

It is plain that it is unnecessary that the current be interrupted by a reciprocal motion only; a rotary motion is also applicable.

Fig. 31 shows a form somewhat analogous in operation to the simplest vibrator, except that the rotary momentum of the armature takes the place of a spring, and the break-wheel which furnishes the light also acts as a commutator to the simple form of motor.

Another way of obtaining a rotary motion within a vacuum is to attach a pendant weight to a ratchet wheel, free to rotate upon a shaft attached to which is the brush. Since the shaft is rigidly sealed into the glass, it is evident that when the bulb be rotated by a motor, the brush will revolve around the

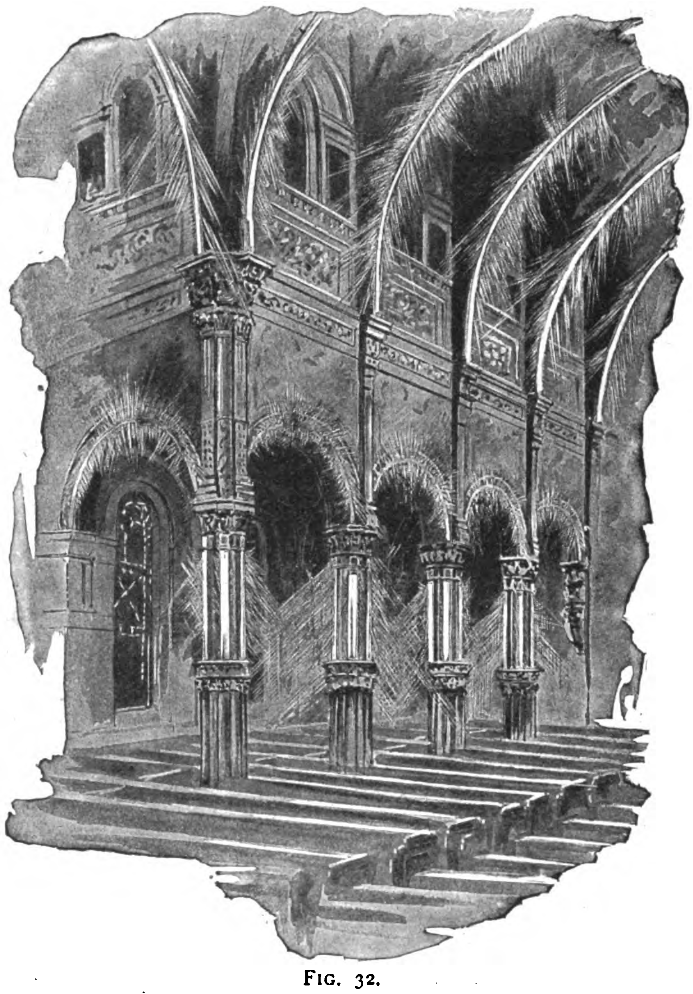

FIG. 32.

break wheel. The fault with the device is that the pendulum will have a vibration of its own, causing the light to waver.

In order that the make-and-break devices dependent upon a rotary motion be absolutely positive, a rotating magnetic field has been utilized. Since the experimental side of these investigations has extended over but a few months, it is at present difficult to say upon which of these methods, developed, the system will take final form.

Returning once more to the subject of the light in the tube. It is interesting to note, that although the most intense light is produced when both of the ends of the tube are connected to the electrodes, it is well known that light also results when the tube is merely placed near an electrode without actual contact. This phenomenon is known as lighting by induction.

If an inductive circuit, sufficiently powerful to brilliantly illuminate a tube four feet long, be transferred to one two feet long, there will appear at the center of this small tube a very intense thread of silvery white light, which undulates as if it were a material substance. It is interesting to contrast the color of the light of these tubes with that of an incandescent lamp. The reddish and wasteful glare of the latter, indicating heat waves, and the pure daylight white of the former, are immediately apparent. It is this difference in color that makes an efficiency calculation so difficult. It is very easy to ask the question: How many watts per candle power? But in most instances it indicates a lack of information on the part of the questioner. The question should be: How many watts per

amount of light equivalent to one candle-power? But even this is not perfectly correct, because it is wellnigh impossible to compare accurately lights of a different color and power of diffusion. When the use the light is to be put to is stated, the problem is much more simple. For instance, if it is to be used to read by, the range of legibility can be made the basis of comparison between the true glow lamp and the candle. This most popular form of illumination, from the twelfth to the beginning of this century, is still the standard of illumination, although it is probable it will soon be deprived of this honor. I may be pardoned for calling your attention to the remarkable intensity of the light in these tubes, in connection with the statements repeatedly made by eminent scientists, that such intensity was an impossibility, and that efforts in this direction were comparable to those wasted on perpetual motion.

The very nature of the light, if it is to be counterpart of the ideal daylight, is such that when a square inch of the surface of the tube emits as much light as that thrown into a room through an aperture one inch square, the want is satisfied. Then the desired illumination can be reached by multiplying the area and length of the tubes, and distributing them in the most advantageous manner, that is, so that the light will fall from all directions. When a considerable area is to be lighted, the most efficient light is the one that is most equally distributed. However, there will always be a demand for units of light. Even this can be satisfied by using a tube of small caliber. This lamp is made by winding a small tube in the form of a spiral, its ends, to which the wires are attached, terminating in oblong bulbs three or four times the diameter of the small tube.

I have previously stated that the alphabet has been constructed of tubes of light. Here are the initials of the body I have the honor to address, A. I. E. E., in letters twelve inches high. The delicate shades of these letters cannot fail to elicit admiration from all who love the beautiful.

The principle of breaking a circuit in a vacuum has many applications to a variety of uses. Among them may be mentioned, advertising signs, decorative electric lighting, electrotherapy, philosophical apparatus, theatrical effects, in the manufacture of ozone, in the kinetoscope, etc., etc.

But the greatest field will ultimately be that of general illumination. You have noticed the tubes extending around this hall. Undoubtedly this is the first time that lighting by tubes has been attempted on so large a scale. You will note the almost entire absence of shadows.

Fig. 32 illustrates what we are coming to in the way of church lighting. For some time past everything has pointed to the general adoption sooner or later of some such form of illumination, and since volumes of light can now be produced, and of commercial intensity, does it not indicate that already this light is a matter for serious practical consideration, and no longer a pyrotechnic curiosity?

But the only way in which one can form a comprehensive or appreciative idea of what advance in this line of work really means, is to compare the situation of to-day with that, not of a hundred years ago only, but with that of only twelve months ago, and note the contrast.

ELECTRIC LIGHTING CONTRACTS IN BROOKLYN.

The Brooklyn aldermen approved of these public electric lighting contracts:

Edison Electric Light Company, 35 cents per light of 1,200 candle power a night, and 17½ cents for lights of 600 candle power.

Municipal Electric Light Company, arc lights of 1,200 candle power 34 cents, and for incandescent lights 16 cents per 1,000 watts metric measure.

Citizens' Electric Light Company, for lighting public buildings, 2.2 cents per lamp hour. For street lighting, 35 cents per light, 1,200 candle power.

There are now 2,250 lights in use, and they will soon be increased by a thousand. It is claimed that the city will save $35,000 by this year's contracts.

THE ELECTRIC CIGAR LIGHTING AND ADVERTISING COMPANY, of St. Louis, has been formed by M. J. Stern, P. Werner, and C. B. McCormack, with a capital stock of $20,000.

THE BLOCK LIGHTING AND POWER COMPANY, with offices at the Grand Hotel, proposes to increase its capital stock from $50,000 to $100,000.

THE OHIO STATE SENATE has passed the Jones bill inflicting the electrical method of punishment in death sentences, and it is expected that the House will concur.

KNOXVILLE, TENN.—The new electric light plant about to be installed by the Brookside Cotton Mills, Knoxville, Tenn., will consist of General Electric Company dynamo and a Ball engine of the Ball Engine Company (Erie, Pa.) manufacture.

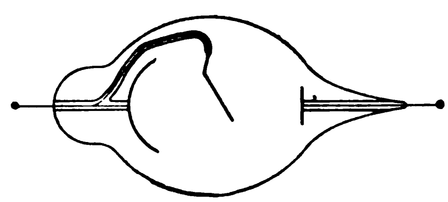
FURTHER PROGRESS IN RADIOGRAPHY.[1]

BY DR. OLIVER J. LODGE.

I HAVE been several times forced to surmise that just as the original Lenard rays are easily stopped by a few inches of air and have feeble penetrating power, so Röntgen rays may be of two or more kinds, perhaps differing in something of the fashion that violet light differs from red; and that, whereas close to the source we get Röntgen and Lenard rays mixed, and a little further off Röntgen rays only, i. e., those which discriminate most clearly and throw therefore the most instructive shadows, so after great obstruction, like a human body, only the most penetrating quality of ray gets through. And under these circumstances the interposition of the palm of one's hand scarcely adds to the shadow, nor do the bones of the palm make their appearance in so prominent a manner as one might expect from the general brightness. Against this, however, is to be recorded the fact that I have taken a photograph of a spine to discover the nature of the damage to a vertebra in a patient, and the details of the processes of the vertebræ.

When the cathode rays do not first strike the glass, but first strike a piece of metal inclosed in the bulb, then its behavior depends largely on what it is connected to. My experiments on this point are not complete, but this much is certain, that if the bombarded piece of metal is attached to the cathode, so that it is unable to receive any electrical charges from the cathode stream, then it either declines to act as a source of rays at all, or else emits a radiation of the most feeble kind, which can without difficulty be attributed to a secondary cause. But on the other hand, if the bombarded disc be connected to the anode, so as to be able to receive the negative charges of the cathode stream, then it acts as a most vigorous source. In a low state of vacuum it will indeed get hot and radiate light, but in a high vacuum every part of the bulb keeps perfectly cool, and the whole energy supplied seems to pass off in X-rays.

The following experiment is worth quoting at greater length: A bulb like this, with concave electrode, having at its



center a rather thick aluminum plate connected to it metallicly (wires protected by glass), and beyond in its shadow the other electrode, was excited either with the cup as cathode or with the cup as anode, and pinhole photographs were taken simultaneously from various points of view, and at measured distances. A glass plate was subsequently put in the position of each of the sensitive plates, and the appearance of the tube as seen through the "pinholes" (which were one-quarter inch diameter), by an eye roving about, were drawn in ink upon the glass. The eye-picture thus obtained was afterward compared with the developed images, and the sources of the radiation thus clearly observed.

When the small flat disc was cathode, every part of the complicated anode appeared strongly and quickly on the plate, especially the tilted and first bombarded portion on a plate placed above the tube. The cathode disc itself did not show at all. On a plate placed below the bulb the anode cup appeared strong, but the tilted disc did not appear. On the other hand it threw a sharp faint shadow of the hole, showing that its focus spot acted as a feeble point source, by reason of a few rays reflected back onto it from the cup.

When the current was reversed, the small disc anode showed faintly, being excited by rays which had penetrated the interposed tilted disc, but again the cathode hardly showed at all, not even the tilted portion on a plate placed below the bulb. By giving a very long exposure (two hours) some impression was obtained, about equal to that from the shaded anode disc; but, of course, if the tilted plate had been under these circumstance an anode, it is well known that a few minutes would have sufficed to show it strong upon the plate beneath.

[1] Abstract from the London "Electrician."

FALK'S X-RAY EXPERIMENTS.

We have received from Mr. Hilbert L. Falk, of New Orleans, a number of remarkable photographs taken by means of the Röntgen rays and showing with apparent clearness the muscular and other soft tissues of the body. Mr.

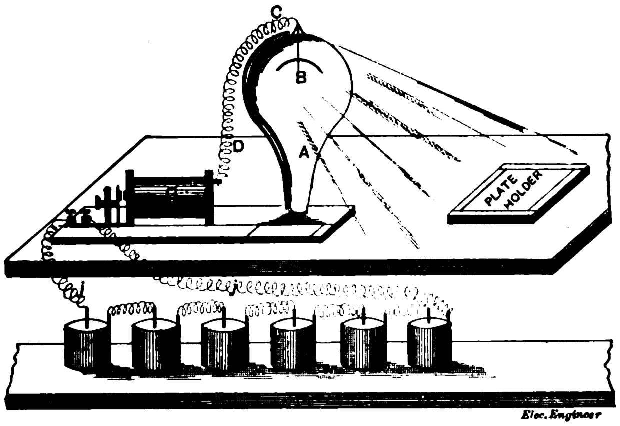


FIG. 1.—FALK'S ARRANGEMENT FOR TAKING X-RAY PHOTOGRAPHS.

Falk's X-ray photos are taken by connecting only the positive terminal of the coil to the tube. He employs in addition an aluminum reflector, C, as shown in Fig. 1

The engraving, Fig. 2, is reproduced from an X-ray photograph of the human brain taken with a photographic plate especially prepared, and it is principally due to the nature of the photographic film that the results are obtained. What this special film is Mr. Falk does not desire to disclose for the present.

Between the head of the subject to be photographed and the

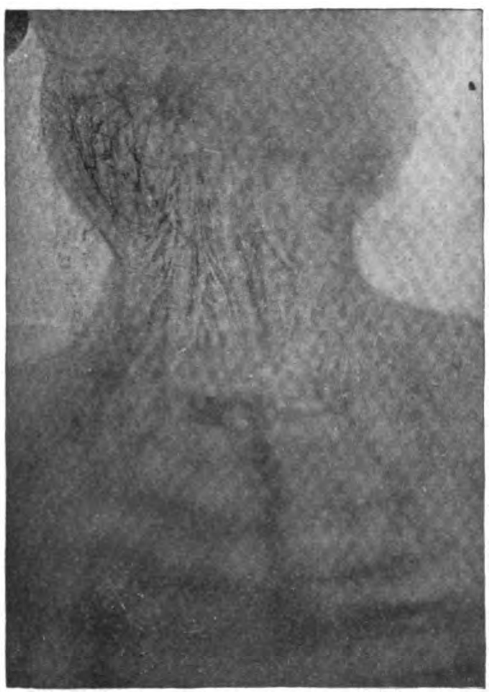

FIG. 3.—X-RAY PHOTOGRAPH OF THE MUSCULAR AND VASCULAR SYSTEM OF THE NECK.

Crookes tube there were placed a sheet of tinfoil and a number of wires attached to the foil at different points. The other ends of these wires were all joined to the negative terminal of the induction coil. A large sheet of bright tin was placed about two feet back of the subject's head. An exposure of seven minutes was required. The dark spot marked X marks the point where the subject photographed was struck by a brick several years ago.

Fig. 3 shows the head and neck, the photograph from which the engraving was made being a photographic reduction from the original full size plate.

We give the above results for what they are worth, and regret that Mr. Falk is not prepared to enlighten our readers

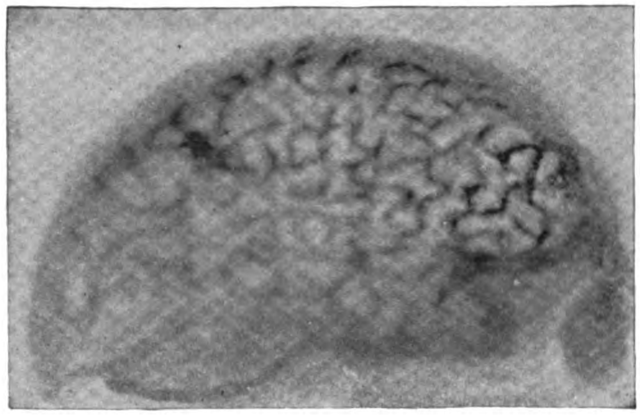

FIG. 2.—AN X-RAY PHOTOGRAPH OF THE HUMAN BRAIN.

on the nature of his plates and screens, among which he uses silicate of soda and tinfoil.

THE DIFFUSION OF ROENTGEN RAYS.

Elihu Thomson

I SENT you some time ago a short article on the diffusion of Röntgen rays, and at the time I was not aware that any work of a similar nature had been done, though, it is true, that certain suggestions had been made as to the turbidity of media by, I think, Lenard and Prof. Röntgen.

I find that Dr. M. I. Pupin has in "Science" of the issue of April 10, given an account of his investigations on the diffusion of Röntgen rays which accords with my results in most important particulars. I was not aware that he had done the experimental work which is described in the article and am now pleased to note that he has gone into the subject very carefully and very thoroughly—in fact, more thoroughly than my time permitted my doing.

These observations on the diffusion of Röntgen rays show that sharp, clear-cut shadows of bones, or objects, imbedded in a considerable depth of flesh cannot be expected where the rays have to traverse a considerable depth of flesh after passing the imbedded bone or object, and that blurring or diffusion which wipes out the image may be so great as to make it very indistinct if large masses of semi-transparent material are between the plate or screen and the object the image of which is to be depicted. It is easy, also, for the experimenter to be misled into thinking that the diffused rays back of the bone or object really have come through that object, when in reality the presence of the Röntgen rays back of the solid object which casts a dense shadow is due to nothing more than the diffusion.

I regret to hear that Dr. Pupin's valuable work in this direction has been interrupted by a serious illness.

LETTERS TO THE EDITOR.

SILICON CARBIDE OR "CARBORUNDUM."

Would it not increase the value of the information contained in Mr. Edison's communication, in your issue of the 15th inst., to explain that the "Silicon Carbide" referred to is the carborundum manufactured at Niagara Falls. I have no doubt many of your readers will be interested in having this explained, as some may wish to experiment, and might fail to recognize the material by its chemical name.

E. G. ACHESON.

Carborundum Company, Monongahela, Pa., April 17, 1896.

CONTENTS.

VACUUM TUBE LIGHTING.

TO those who follow closely the work of inventors and enterprising manufacturers it must have been long since apparent that a constant struggle is going on to provide, at least for interior illumination, a type of lamp having a higher "efficiency" than the incandescent lamp. The improvements which have resulted from this struggle are apparent in the higher efficiency lamps on the market, albeit the life of these lamps may be somewhat shorter than that of their predecessors. It is this factor of life, indeed, to which, in reality, may be traced the quest for that "light without heat" which the writers of magazine articles have for the last ten years or more held up before their readers as one of the three or four great problems now confronting scientists and inventors. If only we could coax from the glowworm its secret we would be at once freed forever from that fearful waste of energy which has always attached to artificial illumination of whatever nature. But unfortunately, the glowworm is uncommunicative, and so we have had to be content with imitating its light as closely as our meager means have permitted. In these imitative efforts the vacuum tube has, of course, played a most important rôle. It is not our purpose here to recall the history of the art, but it will suffice to say that Mr. Tesla's memorable experiments accompanying his Columbia College lecture in 1891, and his subsequent communications and lectures abroad, served, perhaps, more than any other factor in fixing the attention once more upon the great problem before electricians. The means employed by Mr. Tesla to accomplish his results were brilliant in conception, and it is, therefore, all the more to be regretted that that great inventor has allowed his attention to be diverted by other matters, such as his oscillator, which have necessarily stood in the way of working out his vacuum tube light on a commercial scale.

But, in the mean time, others have taken up the subject with no less enthusiasm, though employing means differing radically from those heretofore adopted to accomplish the desired end. Among these is Mr. D. McFarlan Moore, whose persistent work has been steadily kept before our readers and who, last week, read a paper on his most recent progress before the American Institute of Electrical Engineers. The announcement that Mr. Moore was to light the auditorium with vacuum tubes was well calculated to bring out a large attendance. There was an intensely interested crowd of members, who, for nearly three hours, were kept in close attention by the description of a most laborious and painstaking series of experiments, many of which were illustrated by apparatus shown in operation on the lecture platform. Mr. Moore left to the very end the lighting up of the hall by means of his vacuum tube system, and, considering the difficulties he had to contend with, the results shown were extraordinary. Indeed, we have no hesitation in saying that no such results in vacuum tube lighting as shown last Wednesday night have ever been even approached, and had it not been for the ill-hap of an assistant, who switched out two coils of a motor-starting box instead of seven, the effect would have been better still. As it was, however, Mr. Moore may claim the distinction of having for the first time, so far as we are aware, lit up by vacuum tubes an auditorium holding 150 persons sufficiently to enable every one to be clearly seen and ordinary print to be read anywhere with ease. We may add that on an evening subsequent to the lecture the apparatus was operated to far better advantage, and that the room was photographed by the vacuum tube light in a 30-second exposure.

Many will regret that Mr. Moore did not embody in his paper some information as to the energy consumed by his vacuum tubes, since, judging from the wording of a passage in his paper, he appeared to consider this item one of secondary importance. Fortunately, we are enabled to supply this deficiency in Mr. Moore's paper, and to announce the fact that Mr. Moore's twenty-seven vacuum tubes practically

absorbed no more energy than the twenty-five incandescent lamps with which the Institute auditorium is regularly lighted!

To be exact, each of the twenty-seven tubes, which were 7 ft. 6 ins. long, by 1¾ ins. in diameter, took one-eighth of an ampere at 450 volts, as measured by recently standardized Weston instruments; that is, a fraction over 56 watts per tube, or a total of two horse-power for the entire number!

We abhor sensationalism, but cannot resist the expression of our belief that this result, once its import is fully grasped, will influence powerfully future work in this direction. Mr. Moore's system of vacuum tube lighting is still open to improvements in some of its details, but enough has been shown to demonstrate its immediate utility for a number of useful commercial purposes. It can only be a question of time when all its features—including the character of the light, which to some appears too garish, like that of a Welsbach burner—will have been brought into conformity with the demands of the public. As to its economy, that point seems to be well disposed of, so that it remains now only to reduce the apparatus and adapt the light to a commercial basis, and with the simplicity of the apparatus employed this ought to be accomplished in a short space of time. If vacuum tube lighting be not the direction to work in, we would like to be informed what is.

GENERAL ELECTRIC OUTLOOK.

Last week The Electrical Engineer was able by its enterprise to present its readers with the General Electric Company's annual report, although several of its esteemed contemporaries had never a word about it and others had but a brief reference. This report is always one of the leading events of the year, and worthy, therefore, of the effort we made to put it promptly before the electrical public.

As we took occasion to note last week, the General Electric Company would appear on its own showing to be worth about forty cents on the dollar. A concern which with liabilities of some $45,000,000 writes off $13,917,000 to profit and loss, would appear to be in need of reorganization of some kind, perhaps in personnel, but certainly in its financial basis. If the company were alone in the field or enjoyed monopolies, it might recover from such losses, as other concerns often do, but we do not believe that a single well informed person in the electrical field expects to see that done. On the contrary, with the rising tide of competition sweeping away much of its business, and with the tendency to specialization making many of its 9,000 products rapidly out of date or second class, it would seem that, in spite of the financial skill of a high order that the company evidently has at command, it must submit to the impairment of its capital as a permanent condition.

Besides the fact that the huge capital is based on an assumed monopoly which never did and never will exist, it is to be recognized as one of the conditions of the times, that a large number of the local companies are quickly drifting out of touch and sympathy with the company. They complain of bad faith, ill treatment, and high prices, and are beginning to buy freely outside the company's factories, or to be more or less directly interested in rival undertakings. In 1894, the attitude of the old Edison local companies was very warlike and threatening; and if there has been any change since then except for the worse, we have failed to note it in our inquires and observations.

Mr. Coffin's report, as President, notes the "patent deal" with the Westinghouse Company. We fear that Mr. Coffin is not telling all the truth. It doesn't make much difference to anybody what the deal is, but when such papers as the "Philadelphia Record" go so far as to talk of the "business pooling," it is clear that the real facts are leaking out. Our own impression is that a straight out pooling on business exists, and that the percentage alleged to apply to the patents really applies to the amount of sales. In fact, we do not see how anybody but a subtle mathematician, crossbred between a Steinmetz and a Pupin, could work out a "patent" percentage; whereas a rate of division on sales, with sliding give and take, is the easiest thing in the world to work out and to play on the stock market. If our surmise be correct, then Mr. Westinghouse has got the better of his dear friend Mr. Coffin, to a most appreciable degree. But then Mr. Westinghouse as a lamb was never greatly inclined to lie down with the lion—on the inside of that noble animal.

THE X-RAY SOUND WAVE THEORY.

THE theory put forward by Mr. Edison to account for the Röntgen ray phenomenon, namely, that it is a high-pitch sound wave, has not met with general acceptance, and this is scarcely to be wondered at, considering the strong preconceived notions of physicists on the nature of cathode rays and their effects. But in looking over the phenomena recently brought to light by many experimenters in connection with the Röntgen ray, it strikes us that we may have to considerably alter our views regarding the transmission of sound waves through a vacuum. It is an accepted fact in physics that sound will not travel through a vacuum, and when we have reached the highest attainable exhaustion, light then passes through, transmitted by the ether. According to mathematical deductions from the kinetic theory of gases, Schuster's accepted explanation of the working of the Crookes radiometer and the condensation of carbonic acid gas upon glass, as shown by Bottomley, J. J. Thomson, and Bunsen, together with the known presence of mercury vapor, our highest attainable vacuum still contains billions of molecules, and it is still conceivable that if a sound wave in air of small wave length strike the outside of the glass tube, it would be transmitted across the vacuous space not in the manner usually assumed—by rarefaction and condensation—but by bombardment or impact of the residual molecules thrown by the elastic wave in the glass across the bulb. Hence the fact that a vacuum does not stop the X-ray except, as we understand, to weaken it; but, Mr. Edison contends, this cannot be used as a positive proof that the ray is not a sound wave, and he is still searching for facts in further confirmation of his theory.

We note from a cable dispatch in the New York "Sun" that Professor Röntgen has published several important new discoveries connected with the X-rays. He has ascertained that all solid bodies can generate them under the influence of cathode rays, the only difference being as regards intensity. The most intense are produced by platina. He further says that the insertion of the Tesla spark gap break apparatus between the ray-producing apparatus and the Ruhmkorff apparatus is highly advantageous. He has made several experiments which confirm his observation that X-rays can discharge electric bodies, and that air illuminated by the rays can do the same. He further declares that electric bodies surrounded not by air, but by hydrogen or by highly rarefied air, are also discharged by the rays, though much more slowly.

THE ELECTRICAL EXPOSITION.

IT is now officially announced that the National Electrical Exposition will be opened with all appropriate formalities by Governor Levi P. Morton, of New York, at 8 p. m. on May 4. The occasion is likely to be one of great brilliance and interest, and we understand that every effort will be made to render it memorable. The last national electrical exposition, that at Philadelphia in 1884, was opened by Governor Robert Pattison, of Pennsylvania.

The pressure for space at the exposition has been so great that the exhibits have now overflowed to the third floor, of which a large part will be occupied as an annex by the Patent Office exhibit, the Edison Fluoroscope exhibit, and the Practical Electrical Laboratory, together with a number of commercial exhibitors.

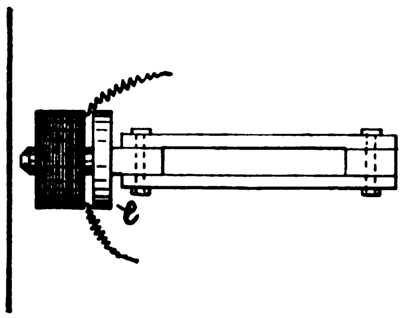
TELEPHONY AND TELEGRAPHY.

FIELD'S LONG DISTANCE RECEIVING TELEPHONE.

HERETOFORE the improvements in long distance telephones have been confined almost exclusively to the transmitter and the line, but that clever and indefatigable inventor, Mr. Stephen D. Field, has recently pointed out an improvement in the receiving telephone which he claims to be of special benefit in long distance work.

The improvement consists in encircling the core or pole-piece of the telephone magnet by a closed conducting circuit, such as a thick ring or disc of copper or other non-magnetic metal as shown in the accompanying engraving at e. When a receiving telephone thus equipped is placed in a circuit near a powerful transmitting telephone in the same circuit, the side tone in the receiving instrument is observed to be of much less volume than in a similar telephone devoid of the closed auxiliary circuit, while if it be placed at a distant station of the same telephone circuit its efficiency in receiving transmitted speech is found practically as high as that of the ordinary telephone, and reproduced sounds are characterized by improved clearness of articulation.

Mr. Field offers the following tentative explanation to account for the peculiar action above described:



FIELD'S TELEPHONE TRANSMITTER.

As is well known, the current flowing in a telephone circuit at any point is of less volume as the point is more distant in the circuit from the transmitting instrument. This is especially true of circuits of high capacity, such as are the usual long line circuits. The phenomenon results from the absorption of the energy of the current in the insulating medium, so to speak. Hence the pulsations of current, particularly the slow pulsations corresponding to the fundamental tones of the voice in the circuit near the transmitter, are of much greater volume than the corresponding undulations at the receiving instrument of the distant station. Now when such heavy current pulsations traverse the magnet coil of the telephone they tend to induce profound magnetic disturbances in the iron of the magnet core; but such large changes are reduced by the damping or demagnetizing effect of currents induced thereby in the copper ring. On the other hand, suddenly and feebly undulating currents produce only slight and superficial disturbances in the pole-piece or core, which affect the diaphragm, but do not affect the copper ring, and are not damped thereby.

In transmission through the line circuit the rapid harmonic waves are more largely absorbed than the slower waves, whereby the consonance or correspondence between the original acoustic vibrations and the telephone current is impaired, and the timbre is altered; but in the reconversion of the telephonic current into acoustic vibrations in the new Field receiving telephone the fundamental electric pulsations are reduced, leaving the harmonic vibrations accentuated in relation to them, and to some extent restoring the original timbre. In short, the reproduction of the transmitted sound in its original quality is attained by two complementary processes of degradation of the vibrations.

BELLEVILLE, ILL.—The Kurtz National Telephone Company, of this city, has been formed with a capital stock of $20,000 to put in 300 telephones in business offices and 200 in residences. A liberal franchise has been granted to W. J. Kurtz, who formed the Decatur (Ill.) and St. Joseph Companies of 600 telephones each, and who now has his headquarters at the National Hotel, Belleville.

ON TELEPHONIC DISTURBANCES CAUSED BY HIGH-VOLTAGE CURRENTS.[1]—III.

BY DR. V. WIETLISBACH.

(Concluded.)

A further means of counteracting the spreading of the high-voltage current through earth consists in insulated cables laid underground from the generator to the points of greatest load of the tramway system, and at these points connected with the rails. By this means, high differences of potential between the different sections of the tramway system are avoided. Of course, the rail joints must be such as to ensure adequate conductivity; this can be enhanced by bare copper wire. With the aid of these various expedients, it is possible to keep down the leakage of current from the rails within certain limits, while, in specially difficult or serious cases, there always remains the remedy of replacing the earth return of the telephone lines by a complete metallic circuit.

Far more difficult is it to deal with the effects of induction, which latter, as already stated, is due to the continuous current, supplied from the generator becoming an undulating one, owing to the motion of the cars. Two causes suggest themselves as operating to bring about this effect. One is the motor itself, during rotation of which successive pairs of commutator segments, connected to corresponding armature coils, are alternately short-circuited under the brushes. The effect produced thereby may be somewhat mitigated by increasing the number of commutator segments which will also result in raising the noise to a higher pitch. The other cause will be found on the line itself, i. e., at the point of contact of the conductor with the collector, in this case the trolley wheel. This latter is fixed to an elastic rod which, upon the car being started, assumes a vibratory motion. Moreover, the contact wire, which in this respect behaves like a drawn cord, also experiences considerable vibrations as the trolley wheel runs along its surface. Consequently, and as in the similar case of a microphone, the resistance at the point of contact undergoes a change, and the result is an undulating current. In fact, the inductive noises separately produced by the two causes referred to, i. e., the motor and the trolley wheel, can be distinguished side by side in the telephone apparatus.

It is curious to note that the noises produced by different electric tramways of similar construction vary considerably in degree, and, further, that these noises are, as a rule, comparatively slight when the tramway has just been opened for traffic, and that only in the space of a few weeks do they attain an intensity which renders telephonic communication difficult. It is not clear how this gradual change takes place, if at all, in the motors; on the other hand, it may conceivably be due to the contact wire, which gradually becomes loosened at the insulators, while the supports, too, attain greater play and move more freely in consequence of the constant vibrations to which they are subjected.

That the mode of contact is also a factor in the phenomenon referred to appears probable from the further fact that the increasing intensity of the noise is observed chiefly on tramways where the current is collected from the contact wire by trolley wheels, whereas tramways using slide contact-bars or shoes experience that phenomenon in a far less degree. An important difference between the two systems consists in the circumstance that where the trolley wheel is used, the contact wire must be suspended as exactly as possible over the axis of the tramway, in order to prevent the trolley wheel jumping off the wire, whereas in the case of the slide-bar or shoe, so high a degree of accuracy is unnecessary, and the contact wire therefore requires fewer points of suspension, nor need it be drawn so tight. In the former case the elastic vibrations of the contact wire are of high frequency, and correspond to the acoustic waves perceived by the ear. In the latter case, on the other hand, the vibrations are of so low a frequency, i. e., so slow, that they fall outside the range of perceptibility of the ear. The aërial crossings and bifurcations of trolley tramways involve much greater difficulty of construction than those of tramways with slide contact, and when the electrical connection or the insulation at those points is defective, such defects will likewise aid in aggravating the phenomenon referred to.

In some quarters great weight is further attached to the lubrication of the contact surface. Be that as it may, the fact is attested and confirmed that some electric tramways produce in telephone lines only slight or moderate disturbances which can easily be obviated or neutralized, whilst other electric tramways cause telephonic disturbances of so marked or violent a character that even mere crossings of telephone lines having metallic return and possessing a somewhat high capacity suffice to render telephonic communication extremely difficult.

In such cases, the only remedy is to bury the telephone lines which are in proximity to the tramway under ground. Having regard to the considerable expenditure which the laying of such cables involves, it would certainly be worth while to further investigate the causes of those telephonic disturbances which may presumably be obviated by very simple means. As regards cost of construction, electric tramways which do not cause telephonic disturbances are in no way more complicated or more costly than tramways which do produce the noises referred to. It is even reasonable to presume that the wear and cost of maintenance are less in the former than in the latter case.

Electric tramways having underground conductors will, presumably, not give rise to telephonic disturbances. On the other hand, it will not be out of place to mention one electric tramway which is now in course of construction, and which it is proposed to work with three-phase current, two of the conductors being constituted by two overhead wires, and the third conductor by the rails. In this case, it is no longer a question of an undulating current whose oscillations might possibly be mitigated by electro-mechanical means, but of a high-tension alternating current, which to the telephone lines simply means unconditional surrender. It is obvious that here the low-voltage, i. e., the telephone, lines will have to give up their earth return over a wide range. But the high-tension system referred to claims to be paramount even in the aërial space. Double telephone wires of low capacity are practicable only for parallel lengths of a few hundred metres; for as soon as the capacity increases, the amount of the intrusive high-tension current exceeds that of the telephone working current. Under these circumstances, the only means of rendering the regular working of the telephone service possible is to bury all the aërial telephone wires underground; only this is no longer a case of equable compromise, but of being overcome by brute force.

In dealing with telephonic disturbances, it must be borne in mind that the radius of telephonic communication from a given center increases, in accordance with the demand of the public, from year to year. Originally it extended to a few hundred metres, then to several kilometres, whilst the radius is at present several hundred, and will soon be several thousand kilometres. With this rapid growth the strain on telephone apparatus and installations increases also as a whole, and it is no easy task to maintain them always in the required degree of efficiency. If, therefore, the working of the telephone is not to be in a great measure restricted and its efficiency impaired by the disturbances caused by high-voltage currents, these disturbances cannot be permitted to make themselves felt in telephones more than other accidental sounds or noises governed by meteorological and other conditions.

A high-voltage installation may produce a noise which per se has no disturbing effect on telephones, but the same telephone line may, in a length of several hundred kilometres, come in collision with 20 or more high-voltage installations, and the sum of all the disturbances produced by those installations collectively will suffice to give a death blow to the telephone.

There is, therefore, a wide and fundamental difference between a short telephone line which only serves to connect two local points (e. g., an electric generating and a motor or other service station), and a telephone installation for interurban and long-distance service. The diffence between the two cases may be likened to that between a horse tramcar jogging along through a town at the rate of 8 kilometres per hour and an international express train covering a distance of thousands of kilometres at the rate of 100 kilometres per hour.

INFRINGEMENT NOTICES IN OHIO.

The Central Union Telephone Company has sent out notices from its offices, at Lima, O., to subscribers of opposition telephone lines in Northwestern Ohio, notifying the users of the telephones that they are using instruments which are an infringement on their patents. This is taken as a warning that suits will soon result.

BELL TELEPHONE STOCK.

Commissioner of Corporations Endicott, of Boston, has ruled that $200 shall be the price of the 21,500 shares of the new Bell Telephone stock, which is to be offered to stockholders before the sale by auction.

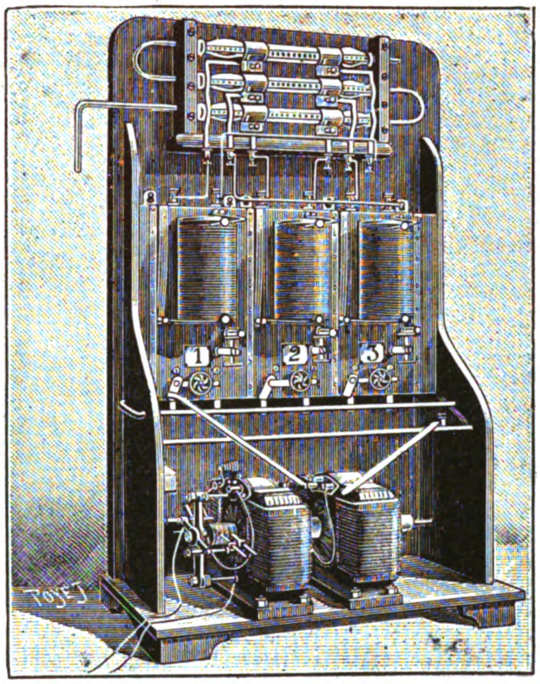
MR. ALBERT L. TUCKER, who has been for several years past connected with the Western Electric Company, Chicago, has been made manager of the supply department of the same company in the place of Mr. E. M. Scribner, who resigned recently.

MISCELLANEOUS.

OZONE GENERATOR OPERATED BY ELECTRIC MOTOR.

THE value of ozone in medicine, the bleaching of tissues, the rectification and artificial aging of wines, and the sterilization of water, air, etc., are well known, but the apparatus usually employed for that purpose is quite cumbersome. M. G. Séguy, after studying and operating a number of models, has arrived at the type of ozone generator illustrated in the accompanying illustration, taken from "La Nature."

On the upper part of a vertical board is mounted the tubular generator proper, consisting of three glass cylinders connected to one another, so as to effect a complete circulation, and leaving the two ends free or open. Each of these cylinders incloses a core of seven tubes, surrounded inside and outside by



THE SEGUY OZONE GENERATOR.

aluminum helices. The current derived from the machine to be described below traverses all these tubes, one pole being connected to the external helices, and the other pole to the internal. Consequently the current to complete the circuit has to pass through the glass, during which operation there are formed myriads of small sparks. This system of helices, consisting of 2,400 turns, has the power of considerably increasing the production of ozone.

The air is taken in by the bent tube shown at the upper left-hand corner, passes successively through the three tubes, and comes out at the other end, after being transformed into supersaturated ozone.

The electric current is furnished by the three secondary circuits of the induction coils, marked 1, 2 and 3, which give 30,000 volts. The primary circuits of these are fed by a small dynamo, placed at the left side at the bottom of the case. This machine furnishes a potential of from six to eight volts, and fifteen to eighteen amperes. The dynamo is driven by a motor mounted on the same shaft, the motor being connected to the city distribution circuits. By this arrangement it is possible to have a continuous production of ozone without much difficulty.

This tubular generator, according to the speed of the interior gases, and according to the section of the discharge tube, can furnish about nine cubic meters per hour of ozonized oxygen, that is, about fourteen to twenty milligrammes per litre.

MR. T. R. MERCEIN, of Milwaukee, the secretary of the Northwestern Electrical Association, has been appointed by the board of directors to represent the association at the New York convention of the National Electric Light Association. This fraternal action is highly appreciated.

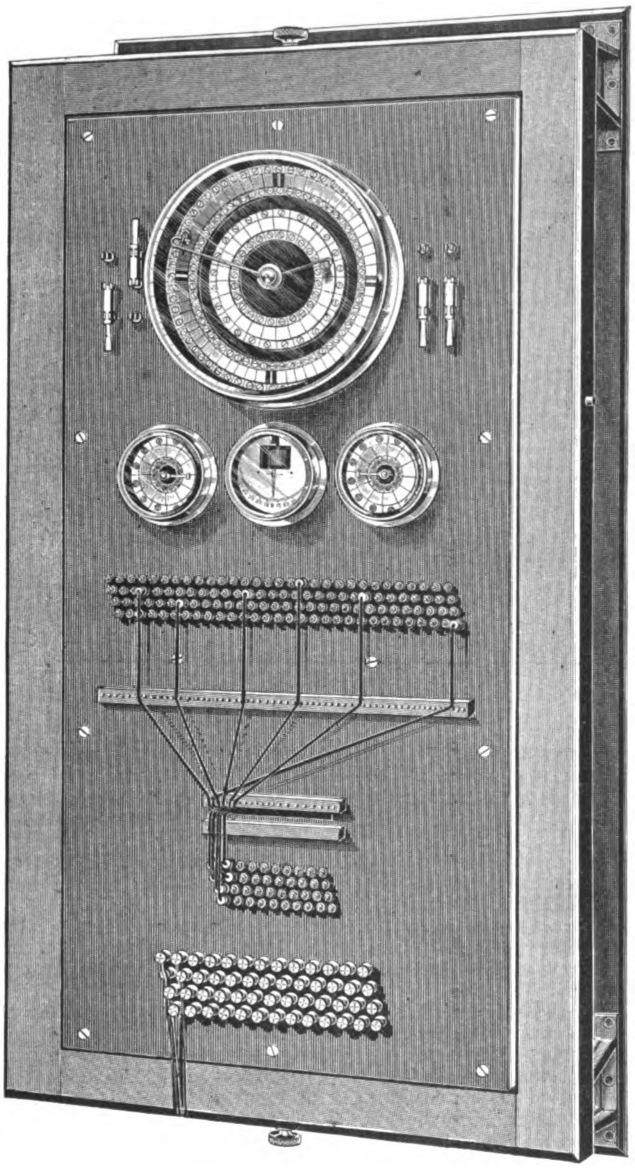
MULTIPLE CIRCUIT CLOSER.

BY

Ernest K. Adams

THIS device is designed to close any number of circuits, at any hour and minute of the day, each independently of the others. It consists, primarily, of a self-winding movement, arranged so that the hour hand makes but one revolution in twenty-four hours. At the extremities of the hands are placed platinum brushes, which sweep over rings cut into sixty and twenty-four segments, respectively, and any circuit having been connected to two segments, one in each ring, will be closed when a bridge is formed between these two by the hands. Excellent contact is obtained by means of a small spring in each brush, which keeps it constantly pressed against the brass.

It is requisite that the circuits should be absolutely independent of each other, in order to secure proper closing of the same. Where circuits are not mutually distinct it is sometimes necessary to employ relays.



ADAMS MULTIPLE CIRCUIT CLOSER.

The clock movement is placed at the back of a wooden frame pivoted vertically in a larger one fastened to the wall. On the front of the small one is a rubber slab, at the top of which, in a brass case, are the above mentioned rings. Each circuit enters at the bottom, and, passing up by means of cords, selects its hour and minute at which it is designed to be closed from the bank of screws, which are connected to the various segments above. These cords are kept taut by weights at the back.

Every hour, when the clock winds itself, the hands in the smaller cases are moved one segment, and, by placing several sets of batteries, preferably dry, in connection with these segments, a new group will be placed in circuit every hour or more, depending on the wiring and the number of sets used. It will be seen that by this arrangement a store (so to speak) of electricity may be laid in and drawn upon intermittently, thereby giving great length of life to the clock and requiring almost no attention whatever.

A galvanometer indicates, when the switches on the left are "thrown," the exact condition of the batteries then in circuit. The right hand switches may be used for winding up the movement, if, by any reason, it should fail.

Among the numerous applications of this apparatus may be mentioned the closing of circuits for: Starting and stopping machinery, opening and closing windows, registers, etc.; lighting or extinguishing either gas or electric lights; throwing on and off of burglar alarms; ringing gongs in schools, hotels and railway stations, and many other uses requiring certainty of action.

SOCIETY AND CLUB NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the 105th meeting of the Institute held at 12 West Thirty-first street, New York City, April 22, about 200 members and guests were present. A paper was read by Dr. D. McFarlan Moore, of Newark, N. J., member, on "Recent Developments in Vacuum Tube Lighting." It was accompanied by numerous experiments, and the hall was lighted with tubes which were suspended horizontally from the gallery in a double row. Owing to the lateness of the hour of adjournment there was no discussion.

At the meeting of Council in the afternoon the following Associate Members were elected: Bert L. Baldwin, Mechanical and Electrical Engineer, the Cincinnati Street Railway Company, 72 Perin Building, Cincinnati, O.; Chas. M. Clark, Student, Electrical Course, Columbia College, residence, 831 Madison avenue, New York City; William J. Clark, General Manager, Railway Dept. General Electric Company, 44 Broad street, New York City; Henry George Field, Consulting Electrical Engineer, Field & Hinchman, 25 Hodges Building, Detroit, Mich.; Curtis B. Flory, Student, Lehigh University, residence 530 Broad street, South Bethlehem, Pa.; Chris. M. Goddard, Secretary and Electrician, New England Insurance Exchange, Secretary Underwriters' National Electric Association, 55 Kilby street, Boston, Mass.; Wm. Steell Jackson, Electrical Engineering Student, Lehigh University, South Bethlehem, Pa., residence, Duncannon, Pa.; C. W. G. Little, Engineer, British Thomson-Houston Company, 38 Parliament street, London, Eng.; Chas. P. McCluer, District Inspector, So. Bell Tel. and Tel. Company, Richmond, Va.; Buckner Speed, Asst. Electrical Engineer, Louisville Electric Light Company, 1521 Fourth street, Louisville, Ky.; Robert M. Thomas, Asst. Chief Inspector, Bureau of Electrical Appliances, N. Y. Fire Dept., residence, 222 West Twenty-third street, New York City; Alfred A. Thresher, Electrical Engineer and proprietor Thresher Electric Company, Dayton, O.

The following Associate Members were transferred to Membership: W. S. Andrews, Electrical Engineer, etc., General Electric Company, Schenectady, N. Y.; Henry G. Stott, Electrical Engineer, Buffalo General Electric Company, Buffalo, N. Y.; Henry S. Carhart, Professor of Physics, University of Michigan, Ann Arbor, Mich.; Russell B. Harrison, President and Electrical Engineer, Terre Haute.

It was decided to accept the invitation of the National Electrical Exposition Company, and hold the annual general meeting in the Exposition building, beginning on May 19.

NEW YORK ELECTRICAL SOCIETY AT THE SPRAGUE FACTORY.

A large delegation of the New York Electrical Society visited the works of the Sprague Electric Elevator Company at Watsessing Junction on April 24 and inspected the large plant that is growing up there with such rearkable rapidity. Mr. Sprague himself received the party and entertained it with an offhand but graphic talk on electric methods as applied to vertical travel. A tour was then made of the shops, after which a collation was served by Mazzetti. The evening was most entertaining and instructive and adds another to the long list of the society's successes.

Exhibition Notes.

THE INTERESTING LOAN EXHIBIT FROM CORNELL UNIVERSITY.

DR. E. L. NICHOLS, of Cornell University, furnishes the subjoined list of the valuable and important apparatus, much of which is of historical as well as experimental interest, to be sent to the exposition. Professor Moler is to set it up there. As will be seen from the explanatory notes, the apparatus is such as to permit of a repetition of some of the investigations at the exposition, where they will be greatly enjoyed, not only by the public, but by experts. The exhibit comes specifically from the Department of Physics and Electrical Engineering of Cornell University.

1. Gramme Machine mounted upon Brackett Cradle.—Constructed in shops of Cornell University by Professor W. A. Anthony (summer of 1875), exhibited at the Centennial Exhibition (Philadelphia, 1876) and at the World's Fair (Chicago, 1893). Capacity, five arc lights, each with 20 amperes. It was in almost constant service from 1875 to 1893, and is still in good order. It was the first machine of the Gramme type built in America. The cradle upon which it was mounted was one of the earliest examples of the Brackett dynamometer, and was designed and constructed especially for this dynamo. It reads in kilograms per revolution.

2. A Reversing Switch.—For use with primary batteries. Designed and constructed by Professors Anthony and Moler for lecture room use, in 1875. (Original model.)

3. A "Doubler," or electrostatic accumulator, involving the principle of the electrophorus. Designed and constructed by Professors Anthony and Moler in 1878. (Original model.)

4. Arc Lamp for Projection (Focusing).—Designed by Professor Anthony, and constructed for him by the Brush Electric Company in 1887. One of the early attempts to simplify the mechanism of direct current arc lamps. (Original model.)

5. Small Double Coil Tangent Galvanometer.—Designed by Professor Anthony and constructed by Fred. C. Fowler, in the workshops of the Department of Physics. It was intended for the absolute measurement of electromotive forces. 1884. (Original.)

6. Early Form of Alternating Current Dynamo for Experimental Purposes.—Designed by D. C. Jackson and constructed by Fred. C. Fowler about 1885. (Original.)

8. Revolving Drum.—Constructed by Professors E. L. Nichols and W. S. Franklin for studying the direction of the electric current. It was driven during the investigations at the rate of 400 revolutions per second. ("American Journal of Science," vol. 37, p. 103, February, 1889. Original.)

9. Ryan's Electrometer.—The original instrument with which Professors Merritt and Ryan conducted their experiments upon transformers in 1889. Am. Inst. of E. E., vol. V., p. 6, 1889.)

10. Spiral Coil Voltammeter.—A much used copy of the original instrument designed and constructed by Professor H. J. Ryan, 1889. (Described at Amer. Inst. E. E., May 22, 1889, vol. VI.)

11. Horizontal-slit Photometer.—Designed by Professor E. L. Nichols and constructed by F. C. Fowler, 1890. This instrument was intended for the study of the spectrum of artificial light directly upon the photometer bar, and has been used in such work. (Am. Inst. E. E. May 21, 1890. Original.)

12.—Discharger used by Messrs. Archbold and Teeple in the study of the Ball and Point Effect.—A peculiar form of alternating arc discharge. (See "American Journal of Science," vol. XLI., 1891. Original.)

13. Alternate Current Potentiometer.—Designed and constructed by Professor G. S. Moler in 1891. It takes the place of an alternate circuit voltmeter, and gives results accurate to within 0.1 per cent. (Am. Inst. E. E., May 21, 1891. Copy of the original.)

14. Curve Writing Voltmeter.—Designed by Professor G. S. Moler and constructed by F. C. Fowler (1892). This instrument, which was used to record the rapid fluctuations of current and potential met with in dynamo practice, etc., was described at the American Institute of Electrical Engineers, June 6, 1892. It has been superseded by the galvanometer of Hotchkiss and Millis, No. 22 of this collection. (Original.)

15. Experimental Transformer.—Designed by Professors Bedell and Crehore (1891) for special investigations of the transformer, with particular reference to effects produced by an alternation of the reluctance of the magnetic circuit. This transformer was used in the experiments of Professor Bedell on the experimental determination of transformer diagrams. (Proceedings of the International Electrical Congress, Chicago, 1893. Original.)

16. Automatic Printing Speed Counter for Dynamo Shafting. —Designed and constructed by Professor G. C. Moler (1893). The apparatus exhibited, which is the original model, has been in continuous service since 1893. (Am. Inst. of E. E., May 17, 1893.)

17. Apparatus for Studying the Heating of Armatures.—Designed and constructed by Messrs. A. H. and C. E. Timmerman (1893). For the investigations performed by means of this apparatus, see Am. Inst. of E. E., vol. X.

18. Alternating current dynamo, constructed in the shops of Cornell University by Messrs. Smith and Hall. (Original.)

19. Water Jet Instantaneous Contact Maker.—Designed by Professors Bedell and Ryan, and constructed by F. C. Fowler (1893). This instrument is used in the study of transformers and other alternating current investigations where the instantaneous values of the varying currents and e. m. f. are to be determined. (Am. Inst. of E. E., Oct. 18, 1893. Original.)

20. Wooden Drum, with coils of wire, used in the experiments of Professors Nichols and Franklin upon the condition of the ether surrounding moving bodies. The drum, which was constructed with a galvanometer, is capable of indicating a current of 6×10^{-10} amperes. It was driven at 3,600 revolutions and suddenly stopped. Such was the delicacy of the apparatus that the absence of effect upon the galvanometer served to show that less than one hundred thousand million millionth of the rotating coil depended upon the rotation of the ether produced by its rotation. (Physical Review, vol I., p. 426, 1894.)

21. Phase Indicator for Alternate Current Motors, etc.—Designed and constructed by Professors Moler and Bedell, for determining the changes in the armature lag of alternate synchronous motors under varying conditions. (Described before the Am. Inst. of E. E., May, 1894.) This instrument was employed in the experiments upon the synchronous motor described by Professors Bedell and Ryan. (See Journal of the Franklin Institute, March, 1895. Original.)

22. Hotchkiss and Millis Galvanometer for the photographic recording of alternating and oscillatory currents. In the example exhibited, which is one constructed and used by them, the mirror has a very small period of vibration.

23. Set of Negatives obtained with the Hotchkiss and Millis galvanometer.

24. Laboratory Transformers.—Designed and constructed by Messrs. J. Swann and H. E.Mole (1896). This transformer is one of a number constructed in the laboratory with particular reference to students' use. (Original.)

25. Apparatus for the measurement of telephonic or minute alternating currents. This exhibit is the original dynamometer used in making telephonic current measurements with the polyphase current method devised by Professor H. J. Ryan. ("The Electrical World," June 23, 1894.)

26. Two-phase Rectifying Commutator used by Messrs. Barnes and Stillwell, under the direction of Professor H. J. Ryan to determine the utility of inductance for constant current regulation from "open coil" or other forms of polyphase generators.

27. Sample of Sheet Iron formed as desired by etching process, applied by Professor H. J. Ryan for the productions of laminated portions of experimental alternate current machinery, avoiding the use of dies too expensive for experimental purposes.

28. Alternate Current 300 Ampere Balance, in which the flexible connections are made of silver foil, designed by Professor H. J. Ryan and constructed in the workshops of Cornell University by Messrs. Tobey and Walbridge. (1890.)

29. The Original Westinghouse Ten-Light Transformer and Switchboard, used by Professors Merritt and Ryan while making their transformer experiments in 1889. (Am. Inst. of E. E., vol. V., p. 6, 1889.)

30. Special Form of Mechanical Contact Maker for obtaining alternate current curves. Used by Professor H. J. Ryan when determinating the behavior of a 17,500 watt transformer in 1892. ("The Electrical Engineer," N. Y., September 28, 1892.)

31. Photograph of a 30,000 Volt, 10 k. w. Transformer, stepping up from 100 volts at 50 p. p. s. Designed and constructed in the workships of Cornell University by H. B. Plumb, 1895. (Described in the Sibley Journal of Engineering, June, 1895.)

TO MEMBERS OF THE A. I. E. E.

At the meeting of the American Institute of Electrical Engineers on ednesday, April 22, a silver matchbox was lost. The matchbox is enamelled in white on one side, a burning cigar with the motto "It all ends in smoke" forming the only too apt design on the enamel. On the reverse side are engravd a crest and motto and monogram, and on the lid a date is engraved. The finder will confer a great favor by communicating with the secretary of the institute.

THE STEAM AND ELECTRIC PLANT OF THE NATIONAL ELECTRICAL EXPOSITION.

IN presenting to the public an exhibition of electrical machinery and appliances which included practically everything of consequence in this line, the National Electrical Exposition Company decided that such an exposition would not be complete without a steam boiler plant up to date in every sense of the word, whereupon a special committee was appointed to secure a strictly modern plant including the leading appliances in the market.

The improved Root water tube boiler, manufactured by the Abendroth & Root Manufacturing Company of New York, was selected to furnish all the steam used at the exposition, there being two equal units forming one battery of five hundred horse-power of boilers. The well known anthracite automatic stoker, manufactured by the Wilkinson Manufacturing Company of Bridgeport (Montgomery County), Pennsylvania, was selected to handle the coal supplied to the fire.

The coal, after being dumped at some distance from the boilers, in the rear, is taken by the C. W. Hunt coal conveyor and carried along the side and a little past the front of the boilers, where it is elevated to a point near the ceiling, from whence it is delivered through tubes to the hoppers of the Wilkinson stokers and, of course, from that point it is fed uniformly down the inclined grates, burning on its way and reaching the foot of the grate as ash, and finally we find it dumped into the ash pit below.

The Hunt conveyor next takes the ash and carries it back to a dumping place some distance in the rear of the boiler, dumping it there automatically. Thus we find the fuel well cared for automatically.

The question of boiler feed-water is fully as important as the coal supply. The water of New York City being exceptionally well adapted for boiler use, no filters or purifiers were considered necessary. The pump supplying feed-water to the boilers is one of the H. R. Worthington Company's make. It will be electrically driven by one of the Crocker-Wheeler Company's pump motors. The pump is one of the "steeple pattern," and combined with its motor presents a novel and elegant appearance.

Two of the Root feed-water devices, manufactured by the Abendroth & Root Manufacturing Company, will work in connection with the boilers, the feed-pump starting the pump automatically when the water level in the boiler falls below its proper level and again stopping the pump when the water in the boilers tends to rise above its normal working level. Thus far the entire working of the boiler is made automatic with the exception of the damper regulation, and here the Locke Damper Regulator Company of Salem, Mass., come to the rescue with one of their damper regulators, and this completes the entire automatic equipment.

So safe and so simple is the operation of this plant, that it has been decided to put it in the charge of a woman to show conclusively that if steam users will put in the best of everything that the market places at their disposal and if they will equip their plants in an up to date manner throughout, they will become so simple in their operation that a woman can operate them as well as the most expert fireman.

The visitor to this exposition will find many other very attractive and useful features which will well repay his careful investigation. The valves, used in the main steam piping, for instance, are especially adapted to high pressures and the usual rough handling. They are heavy straightway valves with an outside yoke and screw, made by the Chapman Valve Company, of Indian Orchard, Mass.

The pressure carried by the boilers will be 125 pounds. This pressure will be carried along the main steam piping to a point just beyond the first engine and there it will be reduced by a Foster reducing valve to 90 pounds, at which pressure it will be carried to all of the other engines on exhibition.

It will be interesting to follow the steadiness of the working of this reducing valve. This may be done by going to the exhibit of the Ashcroft Manufacturing Company near by, where two Edison recording gauges wil be found in operation, one recording the pressure of steam at the boiler and the other gauge recording the pressure on the low pressure side of the reducing valve. The Foster Engineering Company will also exhibit their new automatic safety stop valve, to be placed in the main steam pipe near the boiler. This valve will instantly and automatically close in case of a rupture in the steam pipe, or the breaking of any of its fittings. By this means, the steam in the boiler will instantly be stopped from rushing into the piping and such terrible fatalities as have recently occurred due to ruptured steam pipes will be avoided.

Another valuable feature used in connection with this automatic safety stop valve is found in a pipe leading from it containing a quick closing lever gate valve. When this is opened quickly, the main valve closes instantly, and thus the whole steam supply can be cut off from the main steam pipe at an instant's notice.

The boilers are equipped with steam gauges manufactured by the Ashcroft Manufacuring Company, and with nickel seated pop safety valves made by the Consolidated Valve Company, of New York and Bridgeport, Conn.

The visitor cannot fail to be struck with the beautiful finish of the boilers, which have been designed to include utility, durability, and elegance in outline.

The fine smooth black finish contrasting so strikingly with the polished nickel work is produced by the use of Dixon's graphite boiler front paint, made by the Joseph Dixon Crucible Company, of Jersey City, N. J., whose exhibit will be found in the neighborhood of the boilers. The mason work is certainly of exceptionally fine appearance, and is most creditable to the mason, Garret S. Wright, of New York.

The exhaust piping from the eleven engines will probably interest many of the visitors to the exposition, as it has been used by so many electric light companies for this purpose. We refer to the spiral riveted pipe made by the Abendroth & Root Manufacturing Company.

The battery of improved Root boilers used at the exposition is an exact duplicate of the twelve batteries of boilers used at the celebrated tunnel plant of the Baltimore & Ohio Railroad in Baltimore, Md.

A fine photograph of exceptional size, showing this plant, will be seen on the wall near the boilers.

The engines on exhibition will all be direct connected with generators, with two exceptions, which will be connected by belting.

The engines will be found arranged in the following order, beginning with the engine nearest to the boilers: The Phœnix Engine (the only compound engine); Ball & Wood engine, Straight Line engine, Harrisburg engine, Watertown engine, Payne engine, McEwen engine, Weston engine, (belted); New York safety engine, (belted); Case engine, Shepard engine, Woodbury engine.

The exhaust from all these engines will be passed through a Goubert feed water heater, and then sent through the spiral riveted exhaust pipe (placed outside of the building) to a point above the roof. All the feed water used will pass through this heater, thus supplying the boilers with a bountiful supply of water heated to nearly 212 degrees.

Two concerns share the steampipe covering work, one putting on Keasby's magnesium sectional covering, while the other applies Gilmore's asbestos covering.

A COLLECTION OF INVALUABLE MORSE RELICS.

Mr. E. L. Morse, one of the members of the Historical and Loan Exhibit Committee, has prepared a remarkably interesting collection of early papers, models, relics, etc., relating to Morse, Vail, Henry, O'Reilly, L. D. Gale and others, and to the early days of the telegraph. As the son of Professor S. F. B. Morse, he has, of course, facilities enjoyed by no one else for the presentation of such matter, and the result of his efforts will be of great attraction to everybody. It is expected that this collection will be supplemented by other material from other contributors. The list furnished by Mr. Morse is as follows:

1. Copy of the first wooden telegraph apparatus. 2. Certified copy of the Sully sketch book. 3. Original pen and pencil notes of Morse relating to the telegraph. 4. Letters of Alfred Vail relating to the telegraph. 5. Letters of Peter Cooper. 6. Letters of Cyrus Field. 7. Original 1843 contract of Alfred Vail with Prof. Morse. 8. Piece of shore end of Atlantic cable. 9. Pocket telegraph instrument presented to Prof. Morse by J. D. Caton. 10. Decorations and medals received by Prof. Morse from European governments. 11. Marble bust of Prof. Morse by Horatio Greenough. 12. Portrait of Prof. Morse by Edward L. Morse. 13. Frame containing the following photographs: Birthplace of Prof. Morse, in Charlestown, Mass.; church where Morse was baptized; residence, Poughkeepsie; residence, New York; Academy of Design, copy of "Dying Hercules;" statue in Central Park; monument in Greenwood cemetery. 14. Letter of S. F. B. Morse written to his parents in 1799, when Morse was eight years old. 15. First picture painted by Morse, at the age of fifteen; a family group of his parents, his brothers and himself. 16. A few of Prof. Morse's sketch books. 17. Daguerreotype of Prof. Morse and his eldest daughter, taken by himself in 1840 or 1841, one of the first ever taken in America. 18. Letters from George Wood, Henry O'Reilly, Amos Kendall, Prof. L. D. Gale, William W. Pell, Prof. Benjamin Silliman and others. 19. Caveat for a mode of filling pipe with wire (MS.). 20. Miscellaneous papers, etc.

WHAT EXHIBITORS WILL DO.

NOW that the opening of the National Electrical Exposition is so near, exhibitors are straining every nerve to be ready on time and to make a fine display. We have already given details of what many of them will do, and are now able to supplement that news with further data.

The Electric Storage Battery Company of Philadelphia, besides furnishing the cells charged with Niagara energy which are to run the Niagara model, when "live juice" is not available, will have the following as part of their regular exhibit:

Storage battery of 128 cells in operation, capable of supplying 400 16 candle power lamps (suitable either for central stations or isolated plants) used in conjunction with the Edison system, charged during hours of light load, when current is supplied at a special rate.

Under this method, installations have all the advantages of a storage battery reserve, without the trouble incident to a generating plant, and the cost of light and power compares very favorably with that of isolated generating plants.

Motor driven booster for charging battery in connection with the Edison system, built by the Electro-Dynamic Company, Philadelphia, Pa.

White marble switchboard in oak cabinet, showing latest type of controlling apparatus for storage battery work.

Electric carriage propelled by storage batteries (designed by Morris & Salom). Similar to carriage which won the gold medal in Chicago road race.

Electric launch, 21 foot, propelled by storage batteries, handsomely finished with mahogany and natural wood.

The exhibit will be in charge of Mr. Chas. Blizard, assisted by Messrs. R. W. Rundle, W. O. Knudson and T. B. Entz.

The Adams-Bagnall Electric Company, of Cleveland, will exhibit one of the largest lines of arc lamps ever seen, as the product of a single concern. They will have on exhibition and running a black japan series lamp, shunt; a seventeenth century brass series lamp, differential; an oxidized copper 100 hour lamp, 1,600 alternations; a Japanese copper alternating lamp, 1,200 alternations; an oxidized silver constant potential lamp; an oxidized brass constant potential lamp; a marine lamp, black japan; a 100 hour old gold lantern. There will also be railway arc lamps to run nine or ten in series on the railway circuit. All of them will be of the improved A. B. pattern, about which so much has been said and written of late. The A. B. incandescent lamp will also be shown in its various sizes and styles, all of which have the bulb smoothly rounded and free from the protuberance or nipple that is common to the older forms of incandescent lamps. All lamps, both arc and incandescent, will be open to fullest inspection and test, and measuring instruments will be in circuit.

The Crane Company, of New York City, are exhibiting samples of their specialties, such as extra heavy I. B. gate valves, both with and without by-pass, for 250 pounds working pressure; extra heavy I. B. globe and angle valves for 250 pounds working pressure; pop safety and water relief valves, standard and indicator; extra heavy flanged fittings, plain, tongued and grooved; extra heavy brass globes; also gate valves for 250 pounds working pressure. These will be supplemented by much minor detail apparatus.

The Joseph Dixon Crucible Company, of Jersey City, have space No. 126, section F, on the main floor, where they will give a very interesting exhibit of their graphite and graphite products as related to the electrical and allied industries.

The Niles Tool Works, of Hamilton, O., will exhibit at the National Electrical Exhibition three machines, namely, a five-foot radial drill, to be driven by a motor placed on the floor; a No. 1 horizontal boring and drilling machine driven by a constant speed motor attached to the countershaft; and a thirty-seven-inch boring and turning mill that will be driven by an electric motor attached directly to the driving shaft.

The Brush Electric Company, of Cleveland, Ohio, will occupy no less than 425 square feet with their exhibit at the Electrical Exposition. It will be composed of a historical exhibit and a modern exhibit, the former of which is very old and the latter very new. The historical exhibit will consist of the first Brush arc dynamo which was sold in 1877 to parties in Baltimore who ran it for twelve years. A sixteen light 2,000 c. p. arc dynamo which was run by the Fulton Worsted Mills, Fulton, N. Y., from September 1, 1879, to April 10, 1892, when it was secured for exhibition at the Columbian Exposition. A forty light Brush arc dynamo which was operated by the Berkeley Company in Providence, R. I., from December 1, 1881, to May 19, 1893, when it was purchased for exhibit at the Columbian Exposition. These dynamos are exhibited just as they left the factories years ago. Not a bobbin of an armature has been re-wound, nor a shaft wire or a commutator replaced.

The working exhibit will consist of a new 80 light 2,000 c. p. Brush arc dynamo connected direct to a 60 k. w. 220 volt motor. Eighty double Brush arc lamps will be hung gracefully around the exhibit and operated from the direct connected dynamo.

In connection with the direct connected 80 light arc dynamo will be shown in practical operation a machine running with a load of 80 lights with a difference of potential not exceeding 1,500 volts between any part of the machine or circuits and the machine still maintaining its automatic regulation. To put it more plainly, three circuits will be run direct from the terminals of the dynamo on any one of which circuits the voltage will not exceed 1,500 volts, or in other words, on any one of which circuits there will not be more than 27 2,000 c. p. arc lights. This is an entirely new method of running lamps on an arc dynamo and will be exhibited for the first time in the Brush exhibit.

There will be a 100 light 2,000 c. p. Brush arc dynamo and a 125 light 2,000 c. p. Brush dynamo exhibited. These three large arc dynamos are of the very latest Brush type. They have been recently designed by the Brush Company who have already sold over 20,000 lights capacity of them.

A rack of the various styles of lamps which the Brush Company manufacture will also be exhibited.

TRAVELING ARRANGEMENTS FOR DELEGATES.

The various passenger associations have granted the rate of a fare and a third, on the certificate plan, to delegates attending the convention of the National Electric Light Association, to be held in New York, May 5, 6 and 7. It is positively necessary that delegates when purchasing tickets should state to the agent that they are delegates to the convention of the National Electric Light Association and should obtain from him a certificate that they have paid full fare, which certificate, when properly signed in New York, will entitle them to return passage at one-third the regular fare. It is absolutely necessary that this certificate be obtained when tickets are purchased; otherwise, it will be impossible to take advantage of the reduced rate returning. These certificates are good going three days prior to the opening of the convention and are good to return only three days after the adjournment. The Electrical Special will leave Chicago Saturday, May 2, at 5:30 p. m., via Lake Shore and Michigan Southern road, arriving in New York at 6:30 p. m. Sunday, May 3. Accommodations on this train may be secured by addressing either W. A. Kreidler, 510 Marquette Building, or C. K. Wilber, Western passenger agent L. S. & M. S. R. R., Chicago, Ill. The indications are that this train will be a very heavy one, and Mr. Kreidler has arranged all the details so that it will be as fine a convention train as ever run, if not the finest.

A DOREMUS HISTORICAL EXHIBIT.

A striking figure in the intellectual development of New York throughout the last half of the century has been Dr. R. Ogden Doremus, of the College of the City of New York, Bellevue Hospital, and other prominent institutions. He has always taken an active part in the advance of electricity as a section of the domain of physics and chemistry, and is manifesting deep interest in the National Electrical Exposition. In spite of pressing duties, he has, with the aid of his son, Prof. C. A. Doremus, gathered together some of his more interesting apparatus, and is contributing a display which after all is but the merest fragment of what might be shown and which is exclusive of the working apparatus to be placed in the "Practical Laboratory." It includes, for example, Henry's own experimental induction coil; the famous "Tithonometer" devised by Prof. J. W. Draper in 1842; a "Tithonotype" or copper electrotype of a daguerreotype, and a daguerreotype, taken by the doctor in 1844; electrolytic Marsh apparatus made by Dr. Doremus in 1860; a quantity battery of which the carbons were obtained from iron gas retorts in 1854, each weighing 90 pounds. There will also be two large prisms, 9 inch aperture, for projection of the spectra of metals, each holding 10 pounds of bisulphide of carbon.

These rare scientific curios will be supplemented by one of the cells of the historical old 500 cell battery used at the College of the City of New York, apparatus for fusing metals, apparatus for combustion of explosives in vacuo, and other rare, odd and beautiful things.

AN X-RAY LECTURE FOR THE CONVENTION.

Having in mind the intense interest felt in all that pertains to Röntgen X-rays, the National Electric Light Association has arranged for a lecture on the subject during the convention next week, and has asked Mr. Max Osterberg to give it, with as many experiments and illustrations as possible. This will be brilliantly aided, of course, by the Edison exhibit, which it will in turn serve to explain. Mr. Osterberg has the subject thoroughly in hand and has accumulated a great deal of unique data and material bearing upon it. The lecture is to be given on the evening of May 5.

A PRACTICAL WORKING LABORATORY FOR THE EXPOSITION.

SO many important and interesting pieces of working scientific apparatus, illustrative of some electrical principle or employed in some investigation, have been placed at the disposal of the Exposition management by universities, colleges, and inventors, that special provision has been made for their expert care, so that they can wherever possible be seen in operation by the public. With this object in view, most of this interesting apparatus has now been massed into what will be known as "A Practical Laboratory," in which will be placed all pieces with which experiments or investigations of an educational nature will be made. This will enable the public to witness some striking phenomena, many of which have rarely been demonstrated hitherto outside of the walls of a college or private laboratory.

In order to give proper supervision to this laboratory the Exposition Company has asked Mr. Max Osterberg, of Columbia University, to act as its curator, and that gentleman has very kindly consented to serve. His familiarity with such apparatus and his skill as an experimenter promise a brilliant success for this novel department, which, it is said, has never been organized before at an Exposition, but which realizes in a marked degree the educational purposes underlying the plans of the management.

Mr. Osterberg is now laying out the plans for showing every piece of apparatus to its best advantage. His principal aim is to have everything in such condition that the public can be made to understand some of the most difficult points in electrical engineering within a few minutes. In that way the electrical laboratory becomes a directly educational feature, and if that end is achieved, Mr. Osterberg will feel amply rewarded for the trouble and care bestowed on this exhibit.

Prof. Elihu Thomson is sending much apparatus which will be worked in this laboratory and the entire working instruments of Cornell will be under Mr. Osterberg's care, in behalf of the university.

Among the special attractions will be the material kindly furnished by Prof. R. Ogden Doremus, in behalf of the Bellevue Hospital, which represents also his personal work in connection with the college.

Mr. Osterberg will arrange, by permission of Prof. Crocker and Dr. Pupin, of Columbia University, a set of condensers to show the speed with which a message is sent through the transatlantic cables. A great many other attractive experiments are in store for curious visitors and inquiring students.

A MODEL OF THE ELECTRIFIED ERIE CANAL.

UPON the request of Mr. Frank W. Hawley, who has been so actively and prominently engaged in the application of electricity to the Erie Canal, Mr. Richard Lamb, the civil engineer and inventor, whose electric bank haulage system was put in operation last year at Tonawanda, has worked out a beautiful and costly model of the whole thing; and Mr. Hawley has placed it at the disposition of the National Electrical Exposition. It will be located as an adjunct to the model of the Niagara power plant, which is to stand in the center of the main floor; and the intention is to run it by some of the stored power from Niagara, switching over occasionally to the regular circuits of the building. The model is no less than 40 feet in length, 6 feet in height, and about 3 feet wide. The canal will have eight inches depth of water in it. There will be eight poles, five feet apart, and a one-fourth horse-power motor will furnish a more than liberal supply of motive power to a string of three boats. The latest innovation in canal and lake freighting is the use of steel barges, and the owners of these, the Consolidated Canal Company, who now have a large number afloat, have built three small facsimiles of their craft. The model is not strictly to scale, but the boats are. Each is two feet long. They have been dubbed respectively, Hawley, Lamb, and Wiman. As a setting to the view of the Erie Canal, with its miniature equipment of methods old and new, a scenic artist has painted an appropriate background of rural scenery. The whole thing is cleverly worked out, the "tow" going up the canal and back in about two minutes, the motor reversing automatically at each end of the section.

THE PATENT OFFICE EXHIBIT.

To ship the exhibit of the U. S. Patent Office of 360 models of electrical inventions, for the exposition, required thirty-eight cases. They weigh over two tons. Mr. W. A. Megrath, of the Patent Office, has been specially detailed by the Hon. S. T. Fisher, Acting Patent Commissioner, to take charge of the exhibit.

THE W. J. HAMMER HISTORICAL COLLECTION OF INCANDESCENT ELECTRIC LAMPS.

This collection of incandescent lamps, to be shown at the Exposition, represents to a very considerable degree "The History of an Art." It starts with original models exemplifying the early laboratory work of such men as Changy, Lodyguine, Edison, Sawyer & Man, Swan, Lane-Fox, Maxim, Weston and others. In many cases these inventors and experimenters are represented by numerous forms of lamps, showing in a most interesting way the development in the art as their knowledge and experience increased. To these must be added the following, who are among the many represented in this wonderfully interesting collection, and who by their work have contributed to the development and practical application of the incandescent electric lamp: Muller, Diehl, Siemens & Halske, Siemens Bros., Rogers, Gatehouse, Crookes, Boehm, British Electric, Duplex, Bernstein, Pray, Van Choate, Thompson, Thomson-Houston, Shaefer, Opperman, Vitrite-Luminoid, Novac, Woodhouse & Rawson, Excelsior, Beetz, Greiner, Reinman, Richter, Green, Latimer, de Khotinsky, Goebel, Packard, Stanley, White, Westinghouse, Hammer, Jenny "D. A. C.," Perkins, Cruto, Shultzberger, Sunbeam, Fitzgerald, Franklin, Moses, Kurtzgen, Alcester, Alexander, Gerard, "A. B. C.," Sun, Seel, Remington, Heisler-Bernstein, Victoria, Mather, Swan-United, Edison-Swan, Brush-Swan, etc.

This remarkable collection has been gathered from many quarters of the globe—America, England, France, Germany, Austria, Italy, Holland, Switzerland and other countries contributing. Mr. Hammer started the nucleus of it at Mr. Edison's laboratory in Menlo Park, where he was an assistant in the early days of Edison's work upon the incandescent lamp. Having charge of and assisting in many of the original experiments, tests, records, etc., he made a practice of collecting, with Mr. Edison's permission, certain lamps showing important steps in the work, believing they would some day be of great interest and value. Subsequently Mr. Edison gave him nearly all the lamps he had, which now form an excellent record of his work. To these Mr. Hammer has added from time to time during the past seventeen years. As five years of this period were spent in Europe, he secured many most valuable examples of the early lamps of the foreign inventors. Mr. Hammer also exhibits the only collection in existence of the early substances Edison tried in his endeavors to secure a practical filament for the incandescent lamp.

HEARING NIAGARA IN NEW YORK.

The amount of interest is remarkable that is being manifested in the proposition to enable people at the electrical exposition in New York to listen to the "roar" of Niagara. It is believed to be impossible, but it is not so, as the American Telephone and Telegraph Company will demonstrate next week. Indeed, it is said to be an often tested fact that over the long distance wires, even now, although not arranged for the purpose, the voice of the Falls can sometimes be heard. The company are, however, making plans so that several people can hear it distinctly at any hour and all at once. It is not necessary in making connection at the Falls to go behind the sheet of water in order to get the full effect of sound, but by placing the transmitter near the Horseshoe on the Canadian shore, all the tone and quality will, it is said, be clearly obtained.

The receivers, to the number of thirty or forty, will be grouped around the little model of the Niagara power plant, on the special central platform, in the main hall, so that people will see Niagara run and hear it at the same time; the model itself being also driven with live or stored current from the Falls. It is stated that the "note" of Niagara is four octaves lower than the keyboard of the ordinary piano. Mr. Eugene Thayer, the celebrated organist, says it is not a "roar" at all but a "perfectly constructed musical tone, clear, definite and unapproachable in its majestic perfection; a complete series of tones, all uniting in one grand and noble unison as in the organ." Mr. F. A. Pickernell, the electrical engineer of the American Telephone and Telegraph Company, is now making all the arrangements for this really unique entertainment which will be open to all visitors to the Exposition.

A NOTABLE COLLECTION OF PORTRAITS.

A collection of over 200 autograph portraits comprising all the great celebrities of the electrical art and a number of men now rising to prominence or active in the field has been formed by Mr. W. J. Hammer. These, in nine handsome, framed groups, have been loaned by him to the Exposition, where they will be appropriately displayed. The collection not only includes Americans, but is rich in rare photographs of the leading electrical spirits of Europe.

RELICS OF THE TELEGRAPH.

Mr. A. B. Chandler, president of the Postal Telegraph Cable Company, has loaned the Exposition an interesting frame of very early relics of the telegraph. It contains a piece of the wire used by Morse and Vail at the Vail-Speedwell Iron Works; a piece of tape that is indented with the signals transmitting the news of Henry Clay's nomination; picture of the famous Speedwell shop—then and now;—a portrait of Vail and some views of the early experimental apparatus.

AN EXHIBIT OF GEDNEY'S CHANNEL BUOYS.

One of the most picturesque features of New York Harbor at night is the lane of electrically lighted buoys that marks the passage through Gedney's Channel at Sandy Hook. This is a unique installation, the current being supplied to the buoys from the shore through long runs of submarine cable. These buoys are huge spars of wood, sixty feet long, floating at a slight incline from the vertical, the lamp being carried like the head of a walking stick, and the submerged end being anchored by an iron mushroom weight. The United States Lighthouse Board has kindly placed two of these buoys, ready for lighting, one direct current and one alternating, at the disposition of the exposition management. They will be shown in a length of twelve feet, upright, and the Bishop Gutta Percha Company has been good enough to offer runs of cable to carry current to them, of the same type as that actually supplied for the real work. These buoys will be placed near the entrance to the exposition, with charts and pictures, and the visitor will thus be able to understand how the thing works. Such an exhibit has never before been made, and as stated already, there is thus far only one such installation in the world.

MARRIED.

PALMER—JOHNSON.

Miss Edna Earle Johnson, daughter of Mr. and Mrs. Edw. H. Johnson, of Madison avenue, was married in St. Agnes's Protestant Episcopal Chapel, on April 22, to George Quintard Palmer, son of Mr. and Mrs. Nicholas F. Palmer.

The ceremony was performed by Bishop Quintard, of Tennessee, an uncle of the bridegroom, assisted by the Rev. Dr. E. A. Bradley, vicar of the chapel, and the Rev. Dr. Bruglar, of Port Chester, N. Y.

The bride wore a handsome gown of white satin, trimmed with old point lace, and carried a shower bouquet of orchids and roses.

Her sister, Miss Lillian Johnson, acted as maid of honor. The bridesmaids were Miss Maud Quintard, Miss Laura Belle Spraker, Miss Mabel Adams and Miss Agnes Ely. Frank Fletcher Palmer, a brother of the bridegroom, was the best man, and the ushers were Frederick Palmer and William A. Slayback.

A large reception at the home of the bride's parents followed the church ceremony. The wedding guests included a large number of electrical people, friends of the Johnson family. Some of them came across the continent for the ceremony.

OBITUARY.

MRS. M. I. PUPIN.

We note with deep regret the sudden death of the wife of Dr. M. I. Pupin, of Columbia College, this city. Mrs. Pupin had been in constant attendance upon her husband, who lay seriously ill, and when informed by the doctors that he was at last out of danger, the reaction proved too much for a weak heart and enfeebled system. Dr. Pupin has the sympathy of a host of friends.

RICHARD THOMAS.

We regret to note the death of Mr. Richard Thomas, president of the well known porcelain manufacturing house of the R. Thomas & Sons Company, of East Liverpool, O., whose products are in large use throughout the electrical industries. Mr. Thomas was sixty-eight years of age.

MR. F. JEWETT.—The death is announced of Mr. Francis Jewett, a well-known citizen of Lowell, Mass., and one of the Erie Telephone Company.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE BULLARD TRANSFORMER.

CENTRAL station managers throughout the country are realizing that it is the absence of the constant loss on open secondaries, or what is usually termed the leakage current, which is constantly passing through a transformer,

FIG. 1.—THE BULLARD TRANSFORMER.

whether the lights are on or not, that constitutes the actual economy of a converter. Comparatively speaking, there are but a few transformers on the market at present that realize in any measure the ideal of what a converter should be. But after a long series of experiments, the Bullard transformer,

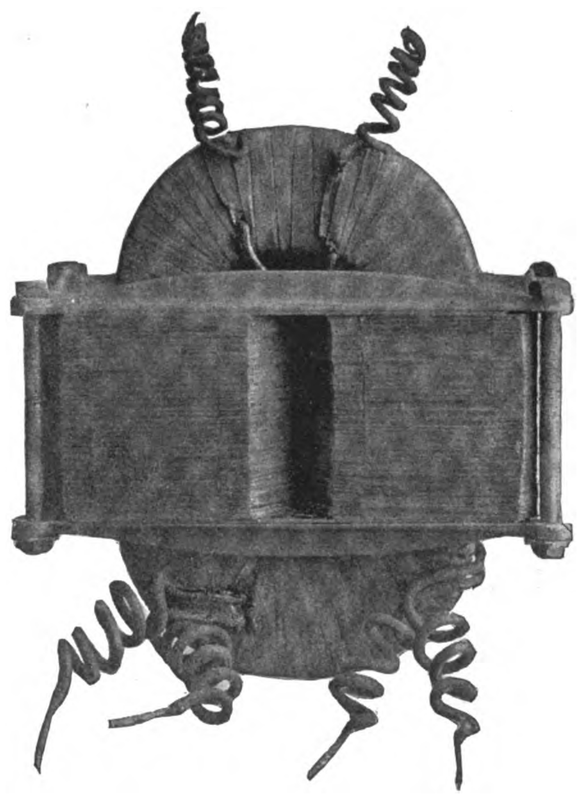


FIG. 2.—THE BULLARD TRANSFORMER.

that has just been placed upon the market, claims to offer to the central station a higher degree of economy than has yet been considered possible when combined with close regulation.

The Bullard Electric Company, of 1563 Monadnock Block, Chicago, manufacturers of the Bullard transformer, have been actuated in their experiments by the belief that many plants in the country desire the most economical converter obtainable, without reference to the slight existing difference in first cost. This company claim that they will readily demonstrate, by offering their transformer for service test, that a net saving of $4 or $5 per year per thousand watt converter capacity can be made by the use of the Bullard converter over the highest grade transformers heretofore upon the market.

A most recent and exhaustive test, made by Prof. H. S. Carhart, of the University of Michigan, on a twenty light or 1,000 watt transformer, is given below:

Efficiency.	Per cent.	Regulation.	Per cent.
Full load	95.18	Full load	2.52
¾ "	95.11	¾ "	2
½ "	94.47	½ "	1.27
¼ "	91.66		

Watts loss on open secondaries: 23.6. Rise in temperature after more than one hour with full load: 21 deg. F. The larger sizes are, of course, proportionately better.

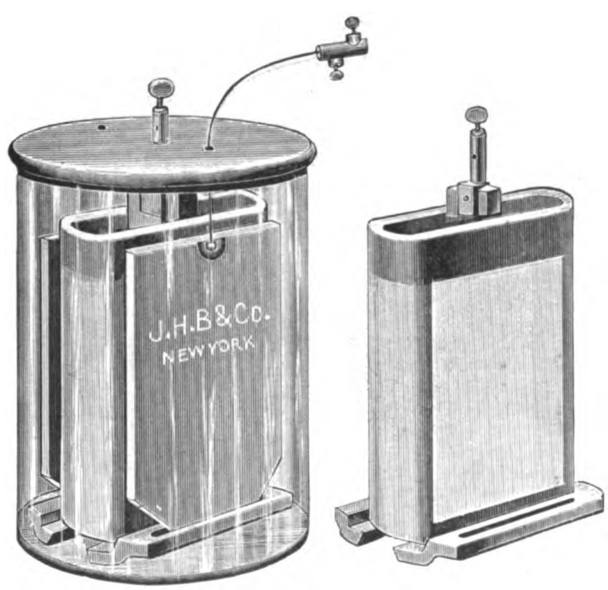
All of the Bullard transformers are made with the greatest care, only mica insulation being employed. Before finally taping the coils, they are thoroughly saturated and boiled in a compound of the highest insulating qualities, and are then baked to a solid mass by being subjected for several days to a high temperature. The transformers are made either for 2,000 or 1,000 volts primary, as may be desired, and for two reductions on the secondary.

Fig. 1 shows the transformer in case ready for installation. Two hooks for adjusting to cross arms are packed with each transformer, so that they may be expeditiously installed on poles. Fig. 2 shows the general arrangement of the coil, ready to be placed in the case. A desirable feature of this transformer is that the coils are not in any way bolted or screwed into the case, the arrangement being such that the bolting down of the cover holds the coil in a firm and rigid position.

The Bullard transformer is made with detached fuse box, as the old method of having fuse box attached to the case of the transformer is attended with so many difficulties in replacing fuses, that it is rapidly becoming obsolete.

THE WHEELOCK BATTERY.

THE accompanying engraving represents the new Wheelock battery, manufactured by Messrs. J. H. Bunnell & Company, of New York. This cell possesses the great advantage of giving two volts and has a capacity of 100 ampere-hours. It accomplished this owing to the peculiar construction of the cell, together with the nature of the strong depolarizing char-



THE WHEELOCK BATTERY.

acter of the solution employed. Inverted T-carbons are permanently set in the porous cup, and flat rolled zinc plates are placed on either side of the porous cup. The zincs at their lower ends dip into mercury troughs which keep them amalgamated automatically. The solution employed is a mixture of sulphuric acid and chromic salts with water, and can be renewed at a cost of 5 cents. The cell is pre-eminently adapted for continuous closed circuit work and can be left on open circuit for as long a period as two months.

AN ALUMINUM FLUOROSCOPE.

BY J. A. LE ROY.

Accidents have led to many discoveries, and a little accident caused me to investigate and bring about the following result: While preparing a fluorescent screen, a small amount of the solution which I used to secure the crystals of tungstate of calcium spilled upon a sheet of tin, upon which it was customary for me to place the cardboard and apply the tungstate. While applying the same to the cardboard the moist spot on the tin plate became coated also. Desiring to know what effect the Röntgen rays would have upon metal coated with tungstate of calcium, I prepared screens made of various metals and coated them with crystals. I compared the metal screens with the ordinary cardboard screens and found that the aluminum screen gave better results; the outline and articulation of the bones of the hand stood out in bold relief and detail. The aluminum being more porous to the rays, evidently allowed them to penetrate to a greater degree than the cardboard. While testing the fluoroscopes, I excited a phosphorescent screen by means of an ignited magnesium tape. After the tape ceased burning, I found, on looking at the phosphorescent screen, fluorescence was caused upon both the cardboard and the aluminum fluoroscope. It was fairly visible in the former; in the second very intense. Now, the question presents itself, Is there an element of the X-rays in phosphorescent substances, and to what degree may they be employed advantageously?

I wish to acknowledge here many courtesies received from Dr. W. J. Morton in placing at my disposal his powerful X-ray apparatus.

PROF. ELIHU THOMSON ON THE FLUOROSCOPE.

Messrs. Aylsworth & Jackson, of Orange, N. J., makers of the Edison tungstate of calcium fluoroscope, have received the following letter from Prof. Elihu Thomson:

"Gentlemen: I tested your fluoroscope last night, and find it to be a magnificent piece of apparatus. I cannot say too much in praise of it, and, so far as I can judge, your claims as to the efficiency of tungstate of calcium in relation to barium platino-cyanide, are fully borne out in the use of the instrument.

"You are at liberty to use this letter in any way that you may desire, as I feel that it will only be conferring a benefit upon investigators, physicians and others to have at their disposal such an efficient means for examinations by Röntgen rays.

"I will certainly take pleasure in recommending the screen to any one who may desire to use such an instrument."

NEWS CLIPPINGS OF THE EXPOSITION.

The Newspaper Clippings Bureau, 1104-5 Bennett Building, this city, makes in our issue this week the offer to furnish a full set of clippings relative to the exposition, and all that is done there, for the strikingly modest sum of $10. It is also willing for a small sum to include a scrap book and assist in arranging it. We recommend all our friends and readers who want a valuable and interesting memento of the whole occasion to accept the proposition, right now. Nothing is more difficult than to get together such material after the event. In fact, it is impossible to do such a thing; but while the show is going on the Bureau, by its facilities, can get the matter together for immediate delivery or to be held as a collection for the subscriber. The idea is admirable, and the work of the Bureau is such as to enable us to recommend its offer for acceptance.

NEW ADDRESS OF THE OKONITE CO.

The old quarters of the Okonite Company, Limited, in Park Row, are soon to disappear before the march of events, and the company has therefore had to give up offices which they have held so long that they might be said to be a landmark in the downtown electrical trade. The company have now moved to the handsome Postal Building, where they will enjoy facilities in keeping with their own push and enterprise. They will be glad to welcome their hosts of old friends at the new home.

THE COMMERCIAL ELECTRIC COMPANY, of Indianapolis, had their factory destroyed by fire on April 20, but resumed business at once, and were able to fill orders at the end of the week.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.
Vol. XXI. MAY 6, 1896. No. 418.

ELECTRIC LIGHTING.

THE NEW 28th STREET STATION OF THE UNITED ELECTRIC LIGHT AND POWER CO., NEW YORK.

NEW YORK CITY was among the very first to take up electric lighting on a commercial scale and hence it has happened that until comparatively recently it has been able to present but few examples of the very latest practice in electrical central station engineering. During the last few years, however, New York has added to its existing stations others of a character second to none in the completeness of their equipment and the ability exhibited in their design. We need only refer to the Duane street station of the New York Edison Electric Illuminating Company, which will be conceded to be without an equal in the world among its own particular type of station. This station distributes continuous current at 220 volts exclusively. As a contrast to it and by way of a comparison, the delegates and other attendants at the N. E. L. A. Convention will have an opportunity of inspecting what may be fairly considered to be the finest type of alternating station at present existing in the United States. This station was completed only last fall and takes the place of the old station of the United Electric Light and Power Company, at the foot of Twenty-eighth street, close to the East River.

The station as it exists to-day is only of one-half the size and capacity for which it is ultimately intended, and from it is supplied the district between the Battery and Fifty-ninth street. Its location at about the center of distribution of load, together with its close proximity to the water front, would naturally make it a most economical plant; and tests which have already been made, though only preliminary in their nature have shown a remarkable economy of operation over the best records of the older stations.

One of the first considerations in laying out work in a large city where property is so valuable as in New York is economy of space, and in this connection it is worthy of note that in this station 20,000 horse-power of engines, together with the boilers, pumps, heaters, condensing apparatus, dynamos and switchboard, and storage for 6,000 tons of coal, are all on a plot of ground 160 feet 11 inches by 197 feet 6 inches. All machinery, including the boilers, is on the ground floor, and yet there is plenty of light, air, and ample space for working around all the apparatus, both for its ordinary operation and for making repairs.

THE BUILDING.—The building already erected, a view of which is shown in Fig. 1 has a frontage of 160 feet 11 inches, and is a steel frame structure with a brick filling in the walls, except on the north end, which is covered by a corrugated iron curtain wall which will be removed when the Twenty-ninth street side is built. This entire front wall is hollow and is carried up above the roof, to prevent the noise from the machinery annoying the patients in Bellevue Hospital, which is directly across the street. The wall is really composed of two walls, one 12 inches thick on the outside, and one 8 inches thick on the inside, with a 2-inch air space between them. These two walls are bonded together at every sixth course vertically by bricks spaced 20 inches horizontally.

Double windows are also placed on this side of the building, to prevent the noise of the machinery from causing annoyance, and this arrangement has been so successful that, standing directly in front of the building, it is impossible to tell whether or not the machinery is in operation. The foundations for all the machinery rest on solid rock, as do the foundations for the building itself, with the exception of one small corner which has no great weight to carry.

THE BOILERS.—The boilers are of the Morrin upright water-tube type, built by the Clonbrock Steam Boiler Com-

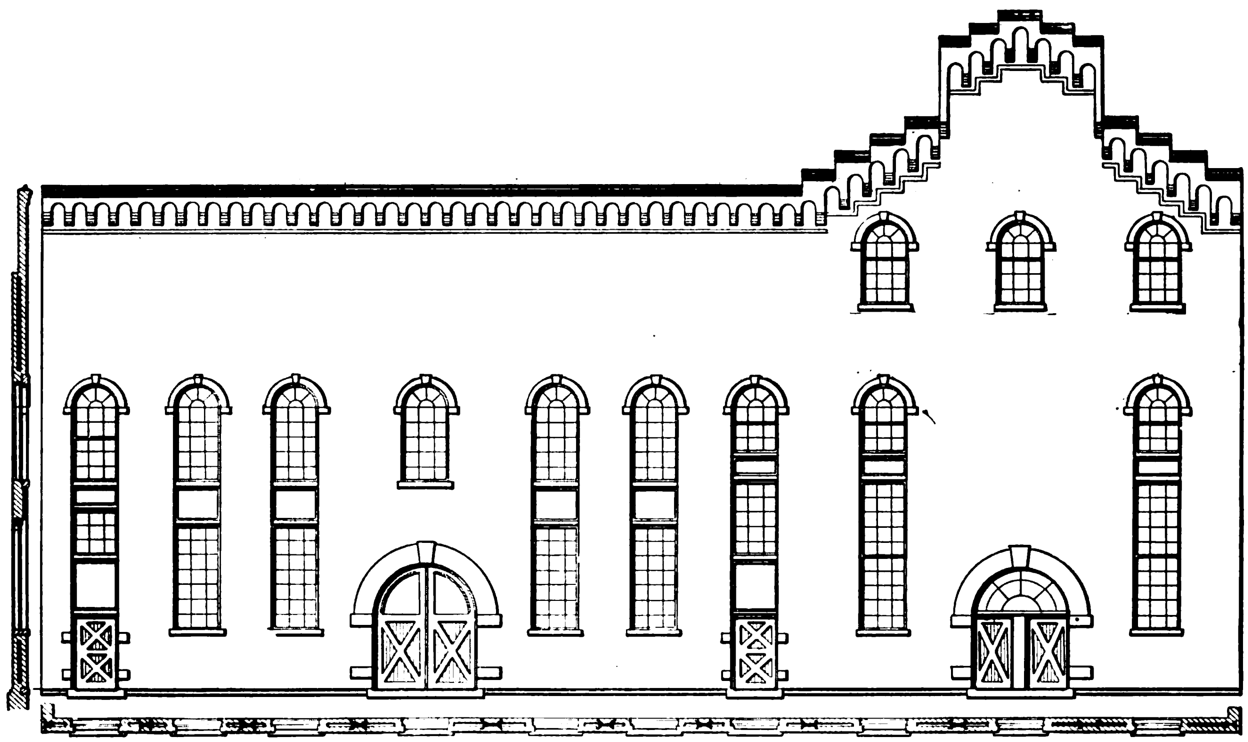


FIG. 1.—UNITED ELECTRIC LIGHT AND POWER CO.'S STATION.—FAÇADE.

pany, and are in 600 horse-power units. Aside from being economical in the generation of steam, they were selected

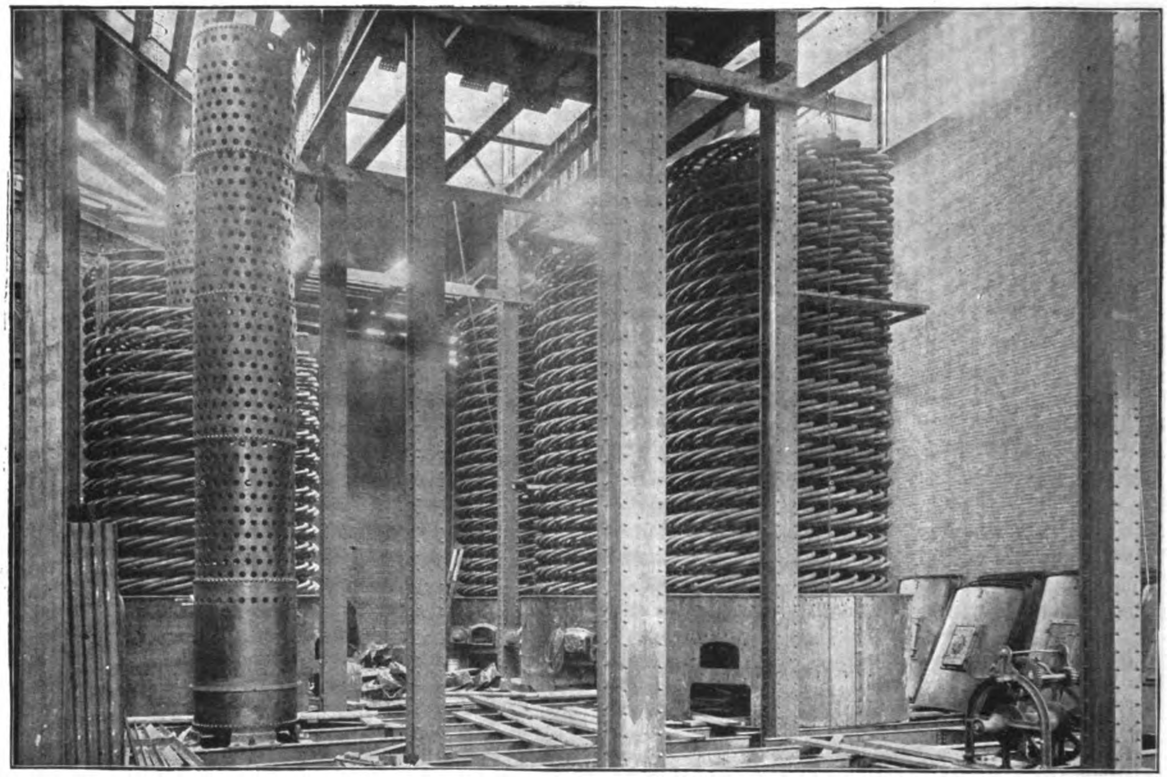

Fig. 2.—United Electric Light and Power Co.'s Station.—Boiler Room.

especially because they occupy so little ground room per unit of capacity. Six are now installed, and six more are required to complete the half of the station now erected. The view in Fig. 2 shows the arrangement of the boilers, as well as their appearance during erection. It will be seen that part of the boilers have all tubes in place, while the shell of one has just been set up, no tubes having been put in it.

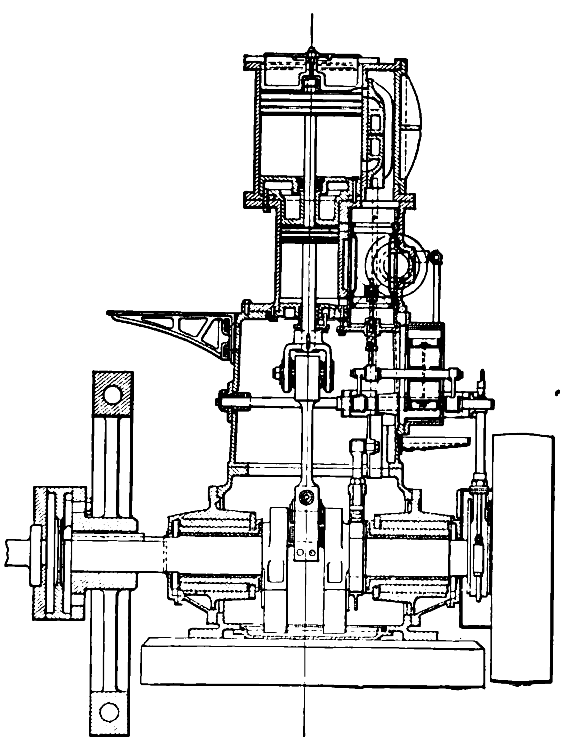

Fig. 3.—Westinghouse Compound Steeple Engine.—Section.

ENGINES.—The engine adopted is a Westinghouse double-acting, known as the "Columbian steepled compound," and is of the same type as those used in the lighting station at the World's Fair at Chicago. In fact, three of the engines at present installed were in service in that station. Fig. 3 shows one of these engines in section. The low-pressure cylinder is placed over the high pressure, and both pistons are connected to the same rod. The crank is inclosed in the same manner as is customary in the more familiar types of Westinghouse engines. The low-pressure valve is operated by a fixed eccentric placed inside the crank case, while the high-pressure valve receives its motion from a shifting eccentric outside the crank case, operated automatically by the governor, which is placed on the shaft outside of the eccentric. The low-presure is of the slide-valve type, while that for the high-pressure cylinder is a hollow piston valve, being constructed in this manner to allow the exhaust from the lower end of the high-pressure cylinder to pass up through it. On account of this construction it is impossible to cushion the valve itself, and this cushioning is accomplished by a plunger, receiving the same motion as the valve, which works in what is termed an inertia cylinder placed outside the crank case, as shown in the cut. This inertia balance is also used for working the engine by hand, the eccentric being first disconnected by throwing over a small hand wheel, and steam being admitted above or below the plunger by means of a small slide valve. The dimensions of these engines are as follows: Diameter high-pressure cylinder, 21½ inches; diameter low-pressure cylinder, 37 inches; stroke, 22 inches. The speed is 200 revolutions per minute and the rated horse-power 1,200 when operating condensing, with 150 pounds initial steam pressure. Fig. 4 shows the four engines and dynamos already installed on the east side of the engine-room.

DYNAMOS.—Each main engine is directly connected to a 600-kilowatt Westinghouse alternator by a rigid coupling, both engine and generator being set on a firm cast-iron bedplate. The generator has but one bearing, the armature being swung between the armature and this single support. Four of these outfits are now erected in place, and four more will be required in the first half of the station. These generators are similar to those used in the lighting station at the World's Fair at Chicago, except that the armatures are wound for 2,500 volts, and are slotted instead of toothed. By this means the noise, which would be objectionable in a thickly populated district, is almost entirely done away with. The alternators are all arranged to give either single or two-phase current. This is accomplished in two of the four machines already in

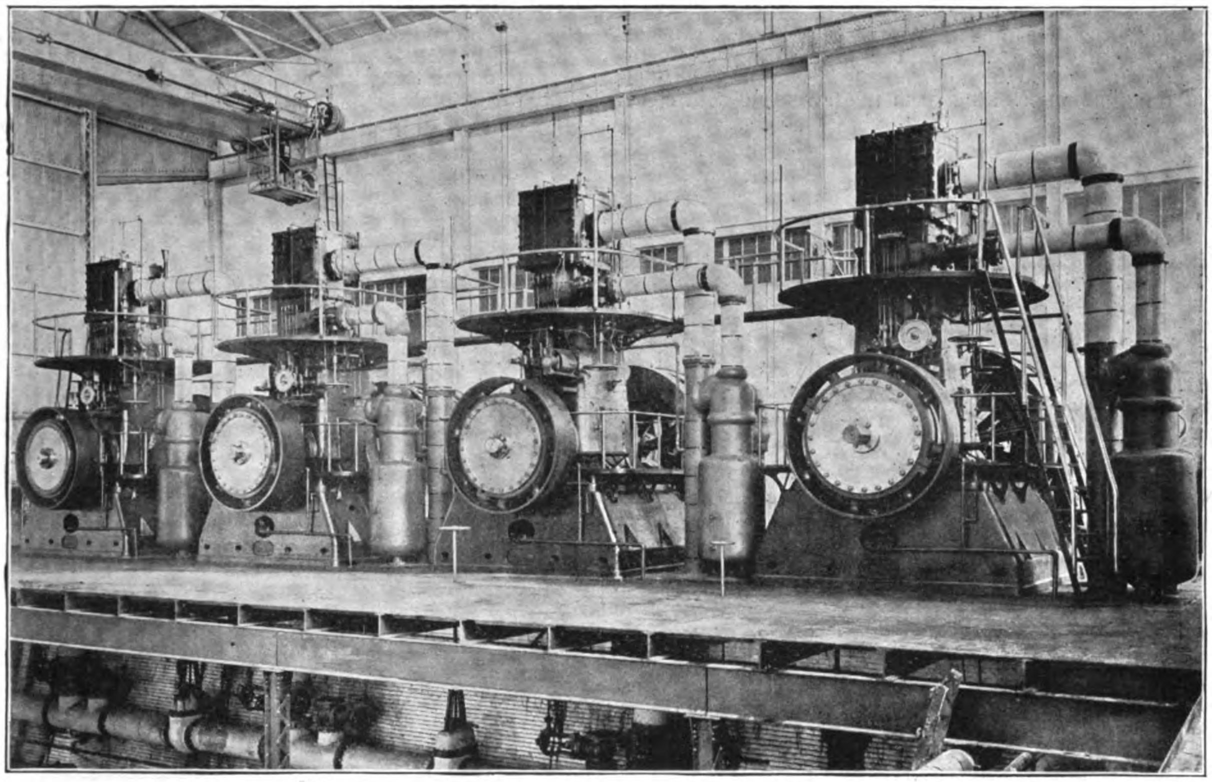

FIG. 4.—UNITED ELECTRIC LIGHT AND POWER CO.'S STATION.—FRONT VIEW OF ENGINES.

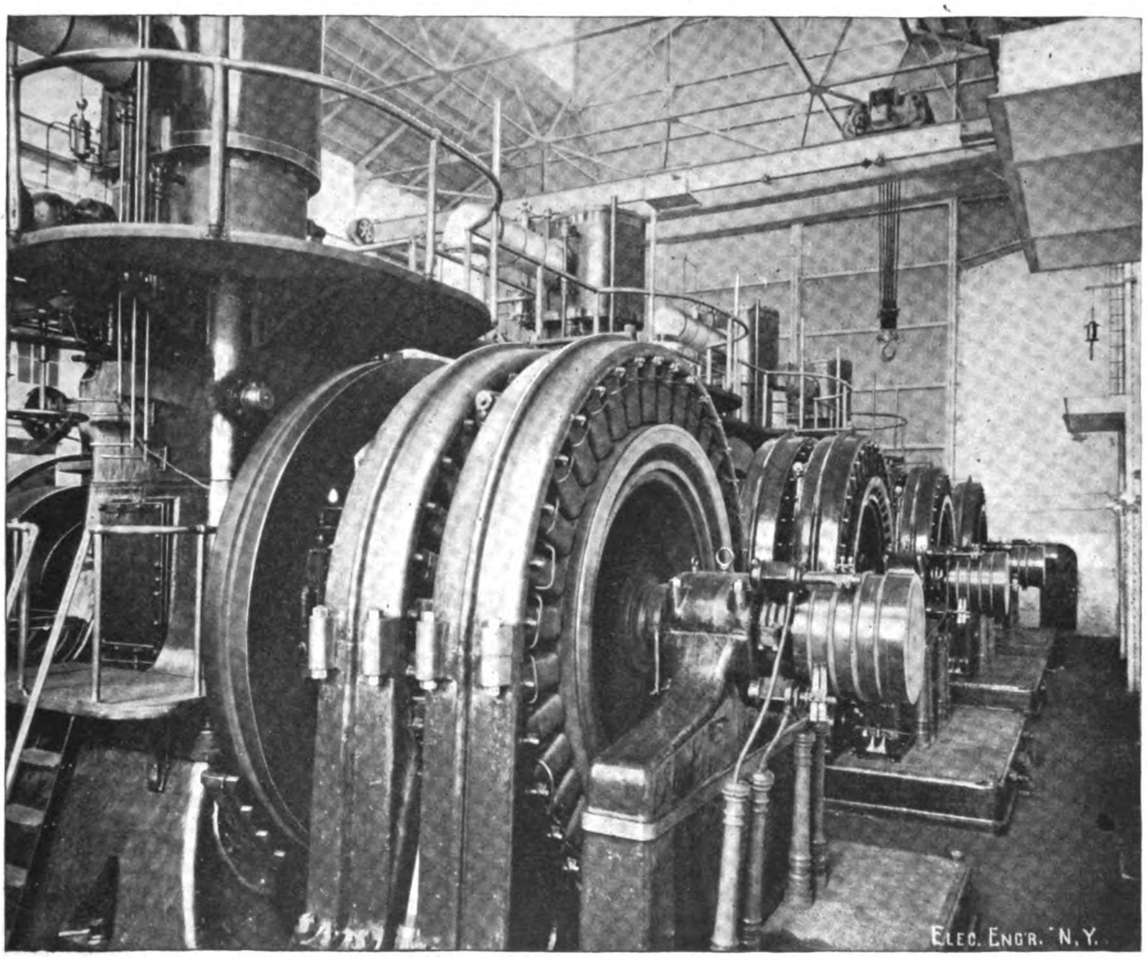

FIG. 5.—UNITED ELECTRIC LIGHT AND POWER CO.'S STATION.—VIEW OF 2-PHASE ALTERNATORS.

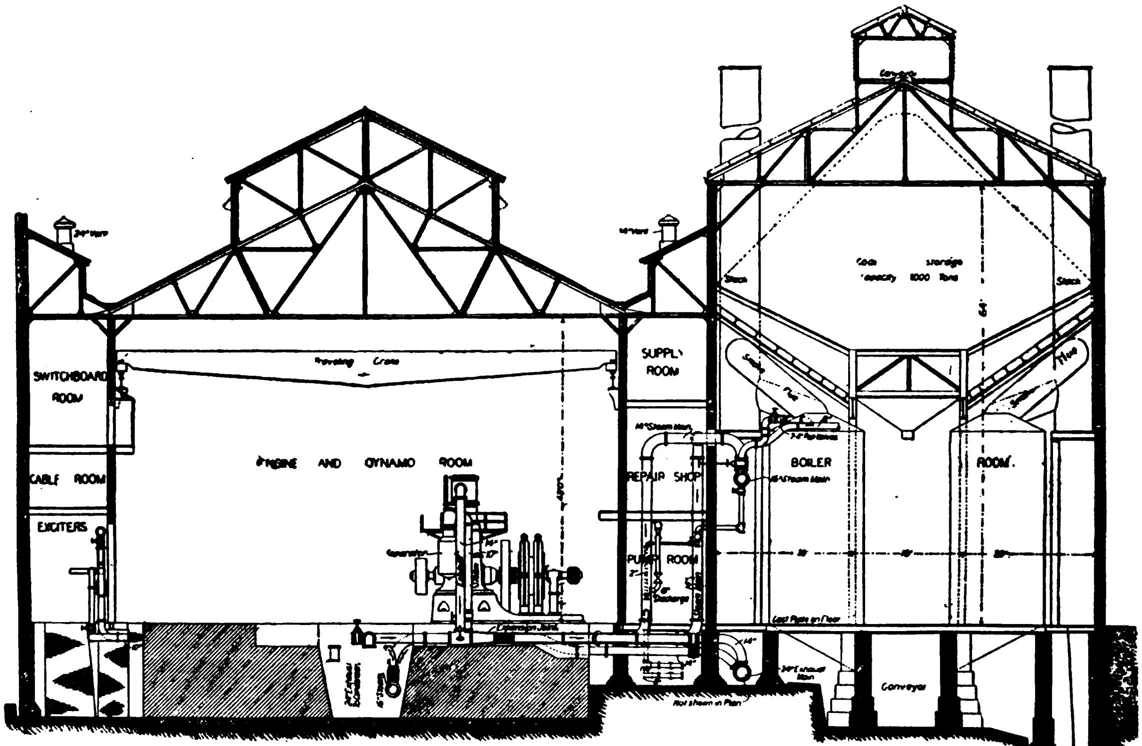
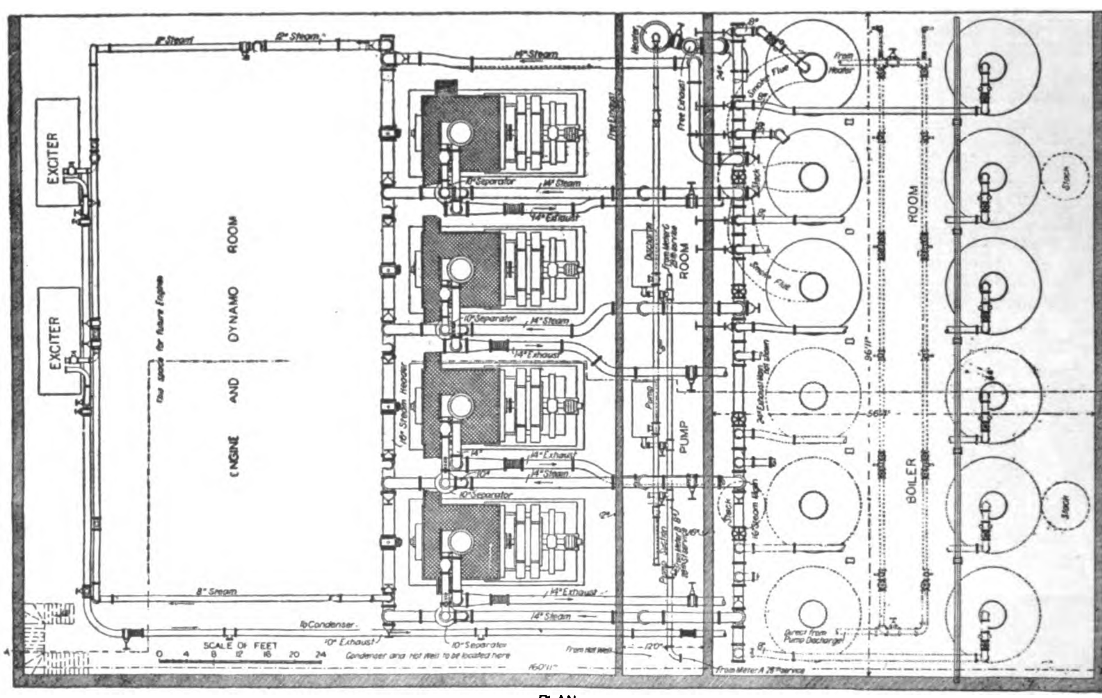
place by two separate armatures on the same shaft, set at the proper angle in relation to each other to give the form of current required. In the remaining two alternators the same result is accomplished with but a single armature. Fig. 5 is a view of the dynamos looking from the Twenty-eighth street side.

street side of the station, and as each has sufficient capacity to excite four alternators, there is always one to spare.

FEED PUMPS.—The feed pumps are arranged in the same manner as the exciters; that is, three are provided, any two of which are able to supply all the boilers in the Twenty-eighth street side of the station at the time of the heaviest load, leaving one spare. These are Worthington compound duplex pumps 9 and 14 by 8 by 10 inches. The steam supply is controlled by a regulating valve operated by the pressure in the feed mains, so that this pressure is always kept constant.



VERTICAL SECTION ON LINE AB OF PLAN



PLAN

FIGS. 6 AND 7.—THE UNITED ELECTRIC LIGHT AND POWER CO.'S STATION, NEW YORK.—SECTIONAL ELEVATION AND PLAN.

EXCITERS.—For exciting the fields of the alternators, 75-kilowatt direct-current Westinghouse dynamos of the railway generator type are used. These are directly connected to 100 horse-power Westinghouse single acting tandem compound engines by means of a flexible coupling. Three of these outfits are provided for the eight alternators in the Twenty-eighth

ELECTRIC CRANE.—The entire engine and dynamo-room is spanned by a Shaw three motor electric crane of 25 tons

capacity. The span from center to center of the rails is 72 feet 3¾ inches, and the crane itself weighs approximately 45 tons. While a crane of this size and character in a power station may appear to some to be in the nature of an extravagance, its use has been fully justified, as it has saved in time and labor more than its cost in setting up the machinery now installed. Moreover, the first cost of the crane is very largely offset by the fact that its presence enabled the roof of the building to be made very light, just heavy enough, in fact, to provide for the wind and snow load, while it would have otherwise been necessary to make every roof truss strong enough to suspend the heaviest part of the engines or dynamos from it, thus materially increasing the cost.

COAL AND ASH CONVEYOR.—The apparatus for handling coal and ashes is indicated in Fig. 6. The conveyor consists of an endless chain of gravity buckets, which are loaded by means of a filler and can be dumped at any desired point. The driver is in the north end of the ventilator over the coal bunker. The coal filler is in a vault under the sidewalk and the coal is dumped into this apparatus through a grating situated at about the street level. After being deposited in the buckets, the coal is carried up into the ventilator over the coal bunker and dumped into any portion of the bunker desired. From the hoppers in the bottom of the bunker, the coal is spouted to the different boilers. The arrangement is such that the coal trims itself and will continue running down the spouts as required and without assistance so long as any remains in the bunker.

When the Twenty-ninth street side of the station is built, a second conveyor running at right angles to the present one will be put in to bring the coal from the water front. As the company does not own the bulkhead on the Twenty-eighth street side, however, it is necessary to cart the coal at the present time.

Under each boiler is an ash hopper delivering the ashes to a second movable filler, which deposits them in the buckets of the conveyor, when it is not used for coal. The conveyor dumps the ashes at a point from which they are spouted over to a tank in the southeast corner of the coal bunker. From this tank they are spouted down and out through the front of the building into carts. By this arrangement the same conveyor handles both the coal and the ashes, and neither is touched by a shovel, except that for the present the coal is fired by hand. This is a temporary arrangement, however, as the boilers are laid out and set with a view to the use of mechanical stokers, which may soon be applied.

FIG. 8.—UNITED ELECTRIC LIGHT AND POWER CO.'S STATION.—VIEW OF EXCITERS AND SWITCH GALLERY.

PIPING.—One feature of this station which is considered of special interest is the arrangement of the piping, which is laid out on what, for want of a better name, the designer has termed the loop system. By this arrangement the size of the pipes required is reduced to a minimum, and without going to the expense of providing a duplicate set of pipes, steam can be shut off of any portion of the system without interfering with more than one engine or its equivalent boiler capacity. As this amount of spare is always carried, it follows that any portion of the steam-piping system can be cut out without interfering with the operation of the station, and the object of a duplicate set of pipes is thus accomplished without the expense of duplicate pipes and without occupying the space required for them.

The main steam and exhaust piping is shown in plan and elevation in Figs. 6 and 7. A 16-inch header is run the length of the boiler-room and a similar header is run the length of the engine-room between the two rows of foundations, and parallel to the boiler-room header. These are the largest live-steam pipes used and there will be none larger, even when the Twenty-ninth street side of the station is complete and the entire 20,000 horse-power is installed. Each of these headers is divided into five sections by means of four gate-valves, located as shown, and each section of the boiler-room header is connected to the corresponding section of the engine-room header by a 14-inch branch rising from the top of one and discharging into the top of the other, a valve being placed on each end where a connection is made to the header. Each boiler has an independent connection to the boiler-room header, supplied with two stop valves, one in the customary position just beyond the safety valves, and the other at the point where the pipe enters the header. This second valve has its stem extended through the wall into the repair shop, so that in case of trouble any boiler may be cut out from a room having no communication with the boiler house.

Each engine on the east side of the engine-room is connected to one of the 14-inch branches previously mentioned, while outlets are left on the engine-room header for connections to the west row of engines as soon as they are placed in position. In case any section of the engine-room header is cut out, one engine connected to this section can be fed directly from the 14-inch branch, leaving only one which cannot be run, and in case any section of the boiler-room header is cut out, no engine need be shut down, as the one connected to the 14-inch branch can be fed back from the engine-room header. One 14-inch branch may at any time be cut out without interfering with

the supply of steam, four of these branches being sufficient to furnish ample steam for all requirements.

The steam pipe for the exciter-engines runs from the north section of the engine-room header around through the exciter-room, and back to the south section of the same header, as shown in Fig. 7. This forms another complete loop, which may be fed from either end in case of trouble with the other, or from both ends in case it becomes necessary to cut out its center.

The steam pipe for the pump-room is arranged in practically the same manner as shown in Fig. 7, except that in this case the loop is fed not only at the two ends but also at three intermediate points, the same as the engine-room loop.

Another special feature of the steam piping of this station is the use of a combined separator and receiver, shown in Fig. 4, as close to each engine as it is possible to place it. This receiver, built by the Goubert Manufacturing Company, contains six times the volume of the high-presure cylinder of the engine, and as the latest cut- off is one-third stroke, it follows that at full load there is at the engine eighteen times the volume of steam required for one stroke. This reservoir prevents the excessive drop in pressure in the pipe when the valve closes, and keeps a practically uniform flow of steam in the pipe in one direction, allowing the use of smaller pipes than would otherwise be required, and doing away almost entirely with the vibration in the pipes caused by the intermittent flow of steam.

All pipes, valves and fittings carrying live steam are made extra heavy to provide for 150 pounds steam pressure, and were tested and made tight under 300 pounds cold-water pressure after being erected in place.

The exhaust piping contains no special features and is clearly shown in Figs. 6 and 7. A second header will be provided for the west row of engines similar to that for the row already in place, and a third header will be provided, running directly to the condenser and connected to all the engines on both sides. Any engine may then be run either condensing or non-condensing.

SWITCHBOARD.—Although provision is made in this station for the switchboard and all the accompanying apparatus, the switchboard room of the old Twenty-ninth street station has thus far been used, as it is advisable to have both boards in close communication while both stations are running and circuits frequently transferred from one station to the other.

The lead wires from the machines consist of lead-armored cables run in iron ducts directly from each dynamo to its panel on the dynamo board. On this board each alternator as well as each exciter has its own panel equipped with the customary appliances, including voltmeter, ammeter, rheostat, fuse blocks, switches, etc. From each panel on this board connection is made to a separate pair of bus-bars on the back and running the length of the feeder board, and here each circuit has a separate panel equipped with a voltmeter, ammeter, continuous registering meters, etc. At a convenient height on each panel is situated a double-pole dynamo change-switch with the circuit leading out from the center and two flexible cables connected to each end. These cables can be plugged in on any pair of bus-bars and a circuit transferred from one dynamo to another by a single throw of the switch. From the center of these switches the circuits run to a third board called the cable terminal board, where, after passing through fuse blocks and a second set of switches used for transferring any circuit from its own panel to a spare panel provided in case it is desirable at any time to cut any feeder panel dead, connection is made to the ends of the cables, which extend down through the floor and out to the subways.

SWITCH GALLERY.—It is intended in due course of time to transfer the entire switching apparatus to the switch gallery, shown in Fig. 8, opposite the dynamos at present installed, and directly above the exciters. This gallery overlooks the entire station and from it all the electrical manipulation will be accomplished with a minimum of labor.

The installation of two-phase alternators was undertaken specially with the object of distributing power, and a number of two-phase motors have already been connected to the circuits.

The entire distribution system is underground, and occupies about 150 miles of ducts. The voltage is reduced to any desired pressure by means of converters placed in convenient locations, usually in vaults under the sidewalk. Continuous registering meters are employed to determine the amount of current consumed; they are of the Shallenberger type.

The station was designed by Mr. H. W. York, C. E., to whom we are indebted for the above details as embodied in a paper read by him before the American Society of Civil Engineers. It presents throughout evidence of the most careful study, and no expenditure has been stinted to make it mechanically and electrically perfect in every detail. We hope at some future time to give the results of some efficiency test when the station shall have reached its proper load.

INFLUENCE OF ROENTGEN RAYS ON THE CONDUCTIVITY OF DIELECTRICS.

At a recent meeting of the Cambridge Philosophical Society, a paper on "The Leakage of Electricity Through Dielectrics Traversed by Röntgen Rays" was read by Professor J. J. Thomson and Mr. J. A. McClelland. This paper contains an account of a series of experiments made with the object of investigating the laws regulating the passage of electricity through dielectrics transmitting Röntgen rays. This phenomenon has been discussed by one of the authors in a paper read before the Philosophical Society on January 27th, and also in one read before the Royal Society on February 13th.

The first experiments relate to the rate of leak through different gases under similar conditions as to pressure and potential gradient. The gases used were hydrogen, ammonia, carbonic acid, air, coal gas, sulphuretted hydrogen, chloroform, chlorine, bromine, iodine, sulphur chloride and mercury vapor. Numbers showing the rate of leakage in these gases relatively to that in air are given. In general, though the rule is not without exceptions, the greater the molecular weight of the gas the more rapid the leakage. In hydrogen the leak was slowest, and in mercury vapor fastest; the rate in the vapor of boiling mercury was about twenty-eight times as fast as hydrogen. The rapid rate in mercury vapor is interesting, for this gas offers great opposition to the passage of an ordinary electric discharge. The rate of leak in the halogens is also very rapid, and a tube containing a charged plate in chlorine gas is a very sensitive and convenient method of measuring the intensity of these rays. The rates of leakage in air at different pressures were investigated; it was found that the rate of leak was lower at a low pressure than at a high one, and was over a considerable range of pressure approximately proportional to the square root of the pressure. The effect of temperature was also investigated, and it was found that through air the rate of leak was lower at a very high temperature than at the temperature of the room, but there was an intermediate temperature at which the rate was a maximum.

The most remarkable thing about this leakage under the influence of these rays is that the rate is almost independent of the potential difference. Thus, when a high potential plate was 5 volts above that of the low, the rate of leak was appreciably greater than when the potential difference was 1 volt, but the rate was no greater when the potential difference was 500 volts than when it was 5.

A series of experiments were made to find how the rate of leakage varied with the distance from the bulb; the bulb was placed behind a metal plate with a hole in it; it was found that in the neighborhood of the phosphorescent glass the reciprocal of the rate of leakage was a linear function of the distance from the phosphorescent patch, but at a greater distance it diminished more rapidly than is indicated by this law. The measurements are not inconsistent with the view that the rate varies inversely as the square of the distance from a place in the neighborhood of the negative electrode. Some experiments on the rate of leakage produced by the rays after passing through a varying number of strips of tinfoil seem to indicate that these rays are not all of one kind.

SPECIFIC HEAT OF ELECTROLYTES.

An interesting investigation on the specific heat of solutions has been given by Herr G. Tammann ("Zeitschrift für Physikalische Chemie"). It is well known that weak solutions of certain electrolytes have a smaller capacity for heat than the water present in them possessed previously to the introduction of the salt, and the object of the investigation is to establish a connection between this phenomenon and the contraction of volume which accompanies the process of solution. This contraction has often been accounted for by the hypothesis of a certain internal molecular pressure. Herr Tammann calculates the specific heat of the water present in a number of solutions of this class on the supposition that their pressure is the increased pressure postulated by the above theory, and he also calculates the specific heat of the dissolved substance, that of the mixture being deduced by adding the thermal capacities of the two components. The theoretical values thus obtained are found to agree closely with the values experimentally found by observing the solutions themselves, and it is inferred that contraction is the sole cause of the diminution of specific heat arising from the presence of the dissolved matter.

THE ELECTRICAL PLANT IN THE SIEGEL-COOPER CO'S. "BIG STORE", NEW YORK CITY.

NEW YORK has of late years seen some remarkably fine buildings erected on its principal thoroughfares, for various uses. As a general thing these architectural additions to the city have been more distinguished for their extreme altitude than for either their beauty or their extent of street front. It is obviously a necessary condition of the dry goods business that the buying public shall be able to roam freely over large floor spaces, where the different groups of articles are displayed to advantage; so that the modern store of this character, even when pretentiously large, does not run up very far into the air, but estimates its importance and magnitude by the number of square feet that it covers. While using extreme care to reach the highest possible efficiency and economy in all devices and apparatus used in such establishments, the managers of these businesses still desire to arrest the attention of the town, and to make their stores the theme of general conversation, and hence they are tempted to try experiments of one kind and another which shall help them fill the public mind and eye while they empty the individual purse. The problem here suggested has been dealt with in a variety of ways, and one of the most notable instances of its solution is found in the building here illustrated—Fig. 1—the "Big Store" of the Siegel Cooper Company.

MR. HARRY ALEXANDER.

This store owes its origin to the enterprise of a firm which has already made its mark in Chicago, and which comes to New York hoping by its experience and its special methods to reap an even richer reward than in the metropolis of the West. One great feature in connection with the building here shown is that special reliance is placed upon the use of electricity, which, while being used for every purpose, including light, heat, power and ventilation, is also utilized as a means of attraction. Probably no other private edifice devoted to trade has ever had such a blaze of light or more ingenious specialties in the nature of advertising display. It will dominate, in a spectacular way, its whole territory, being at the very heart of the uptown shopping district, and its dome will be even more brilliantly outlined against the nightly sky than is the tower of Madison Square Garden.

The building, of which we show a perspective view, is 196 feet 6 inches front on Sixth avenue, extending down West Eighteenth and Nineteenth streets a distance of 460 feet. There are six floors, with a deep basement, a cellar and an extra story for special purposes on the roof. Altogether the floor space available is 611,880 square feet, or over fourteen acres. Rising far above the roof is the tower, which, however, is not for mere ornament, but will have rooms in it, one of which will be Mr. Siegel's private office. The height of the tower is 225 feet, and above that will rise a flagstaff, the tip of which at night will gleam with a 500 candle power incandescent light. The whole front of the building will be brilliantly studded with light, in a manner to be described later, while from the tower, the revolving beam of a searchlight will serve as a constant reminder of the store to a city full of women keen for bargains.

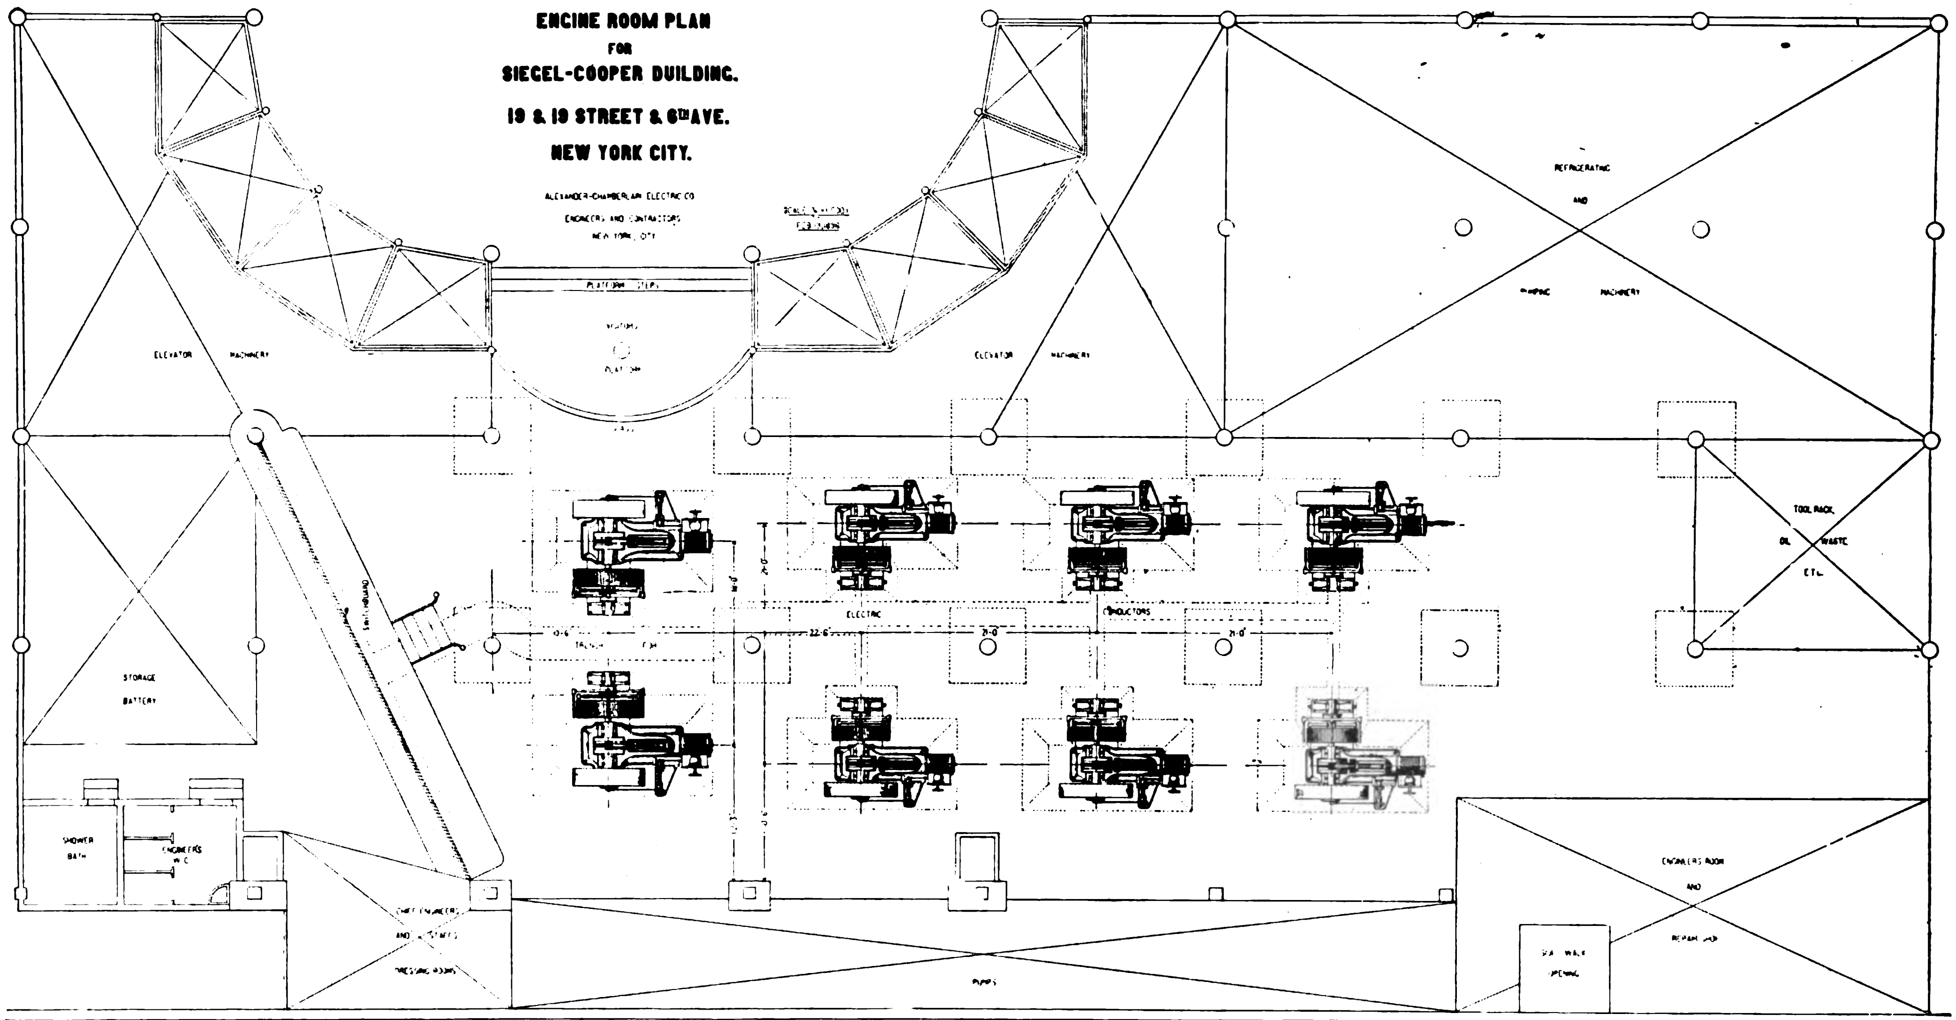
The plans and specifications, including all details of the work described in this article were drawn up by the Alexander-Chamberlain Electric Company, of this city, and were laid out under the direct personal supervision of Mr. Harry Alexander, whose portrait is vignetted at the head of this article, and for which work he acted as designing and consulting and now as contracting engineer.

Although this huge enterprise is a large undertaing, the work has been so well laid out and planned that the Alexander-Chamberlain Electric Company are well in advance of their work despite obstacles constantly confronting them such as change of plans, labor troubles, etc., which are inevitable in a building of this description. They are well equipped at the building with offices, drafting, store rooms and workshop, and with telephones both private for use through the building and connected with the outside world, making it a complete, perfect outfit; only with which work of such magnitude can be carried on successfully.

FIG. 1.—THE NEW SIEGEL-COOPER STORE, NEW YORK.

To begin with the generating plant, Fig. 2, which occupies the southerly wing of the basement and as shown on the plan; this will consist of no fewer than eight units. There will be six smaller units of 100 kilowatts and two larger of 150 kilowatts. These units will consist of Siemens & Halske dynamos, direct connected to Ball & Wood engines.

The engines are of the latest type for direct connected work. Two have cylinders 21 by 16 and are rated at 225 horse-power each. Six have cylinders 17½ by 14 and are rated at 150 horse-power each.



Each engine is equipped with the new Ball & Wood oiling system, gravity feed, dispensing entirely with the use of oil cups, and admitting of close inspection by the engineer while in active service.

The Siemens & Halske dynamos are of the familiar direct connected type, with the outside armature and peripheral commutator, and will provide current for 6,500 incandescent lamps, 3,000 of which are used for display purposes on the front of the building; nearly 800 arc lights, and a large variety of electric motors, besides the motors used for running the electric elevators. Orders have just been given to place a small auxiliary unit to the east of the other equipment already laid out in the diagram shown herewith.

This unit will consist of a 30 kilowatt direct connected multipolar Eddy generator and a Ball & Wood engine. This combination has been set on foundations at once and started to furnish current for various operations connected with the erection of the electrical work. The two large units, representing no less than 450 horse-power, are intended to be used for power purposes, and the battery of six smaller ones is for the electric lighting service, but arrangements have been made in the design of the bus-bars as shown in Fig. 4 for connecting all dynamos together.

FIG. 2.—THE NEW SIEGEL-COOPER STORE.—PLAN OF ENGINE AND DYNAMO ROOM.

In order to operate the "sweeping" lights and for illumination of the windows, dome, searchlight, etc. ,a storage battery consisting of 110 working and 20 c. e. m. f. cells will be installed. The capacity of this battery will be 1,000 ampere hours at a minimum pressure of 1.9 volts per cell. Arrangements will be made for charging and discharging this battery two sets in multiple at 110 volts or two sets in series 220 volts as occasion

may require. It is contemplated using independent plates of low broad form, each plate being arranged so as to be taken out of the cell should it be necessary and replaced by another without disturbing any connections or stopping the operation of the battery.

the marble slabs and also a platform reaching in front and behind the switchboard proper, permitting quick and easy access to connections and switches, while allowing the operator an unobstructed view of the engine room. Leading to this platform is an iron stairway in front and an iron ladder

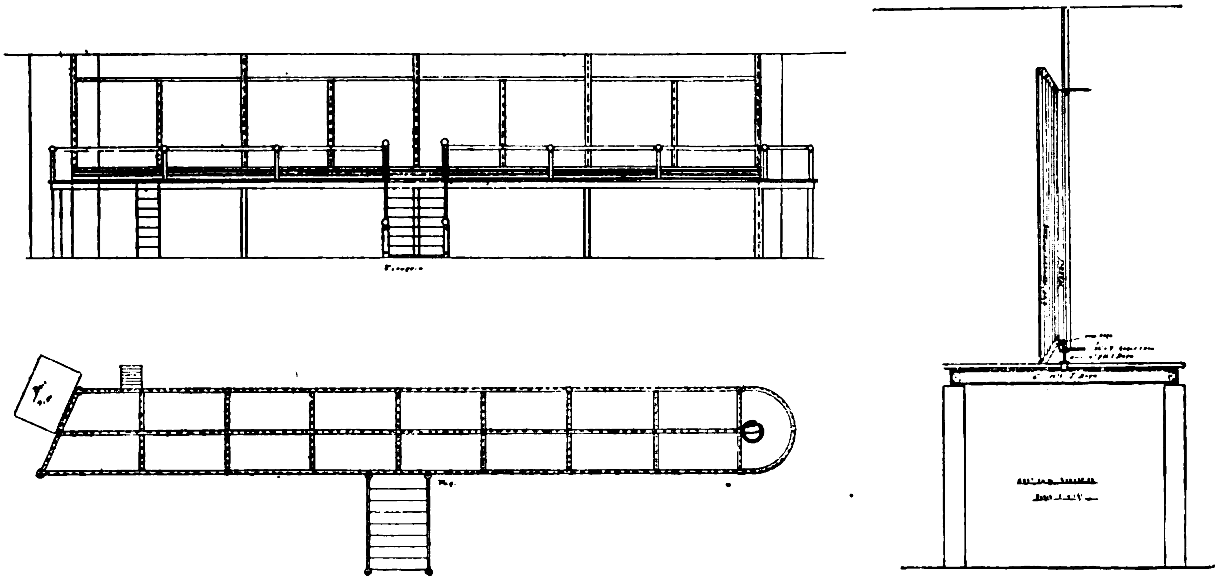


Fig. 3.—The Switchboard, New Siegel-Cooper Store.—Plan, Elevation and Section.

These batteries will be charged from the bus-bars, a booster of from 20 to 30 volts and 250 ampere capacity being placed in the circuit to raise the pressure when charging. This booster will be direct connected to a motor and will be controlled by

behind, both having brass rails which are carried around the board, giving the whole a very handsome and chaste appearance. The framework is now being erected and when in place the marble slabs will be mounted and drilled while in position

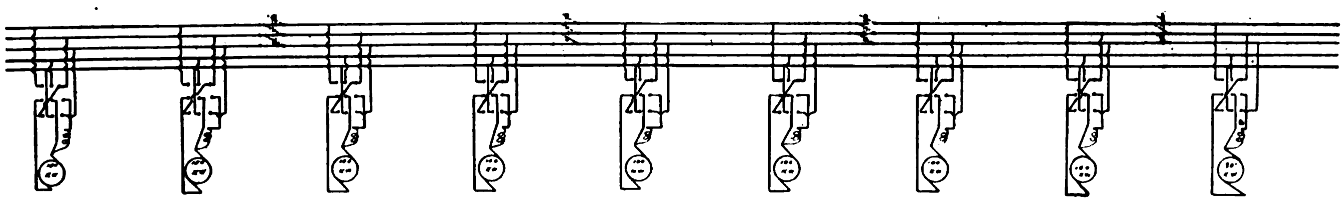

Fig. 4 —The Siegel-Cooper Store.—Method of Dynamo and Bus Bar Connection.

a double-throw switch, which, when thrown one way, will make all necessary connections for charging, and when thrown the other way will allow the batteries to be discharged.

All the circuits will be carried under the dynamo room floor

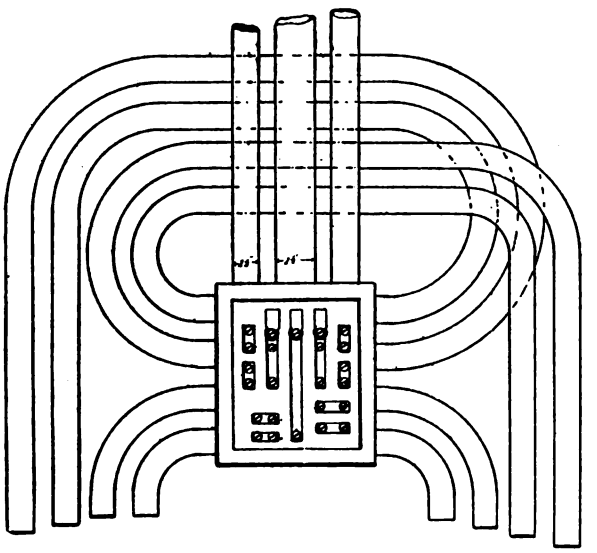

Fig. 5.—The Siegel-Cooper Store.—A Bit of Interior Conduiting.

to a magnificent white Italian marble switchboard nearly fifty feet long, set slantingly as shown in the cut. This switchboard is raised six feet above the floor level on a framework of structural iron similar to the construction used in modern steel buildings. This framework comprises the supports for

by a portable electric drill. Fig. 3 gives a plan, elevation and enlarged section of this framework.

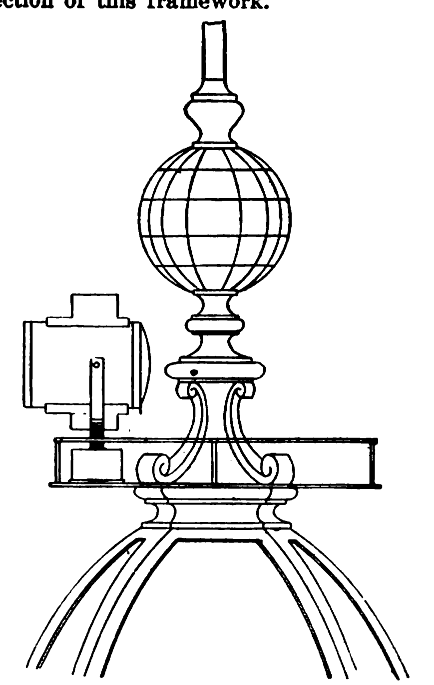

Fig. 8.—The Cupola with the Search Light.

The bus-bars and connections of copper weigh nearly two tons. A diagram of these is shown in Fig. 4.

The instruments mounted on the board are those of the

Weston Electric Instrument Co.'s illuminated dial pattern. There are two ammeters of 1,400 amperes, six of 800, and one of 200, all being of the detached shunt type, and five Weston voltmeters all reading up to 270 volts.

The switches are of a spiral jack-knife pattern. The "backbone" of the arm, so to speak, is made of brass tube slotted to receive a copper blade, held in by special arrangement of plugs and nuts, making a secure

As shown in the section, Fig. 3, the whole switchboard is inclosed in a mahogany frame of 6-inch by 8-inch molding.

It being thought advisable to make this plant one of the show features of the building, a platform is being erected which will allow visitors an unobstructed view of the whole engine room. This platform will be separated from the engine room itself by a plate glass front.

In order to facilitate repairs, should any be necessary, an

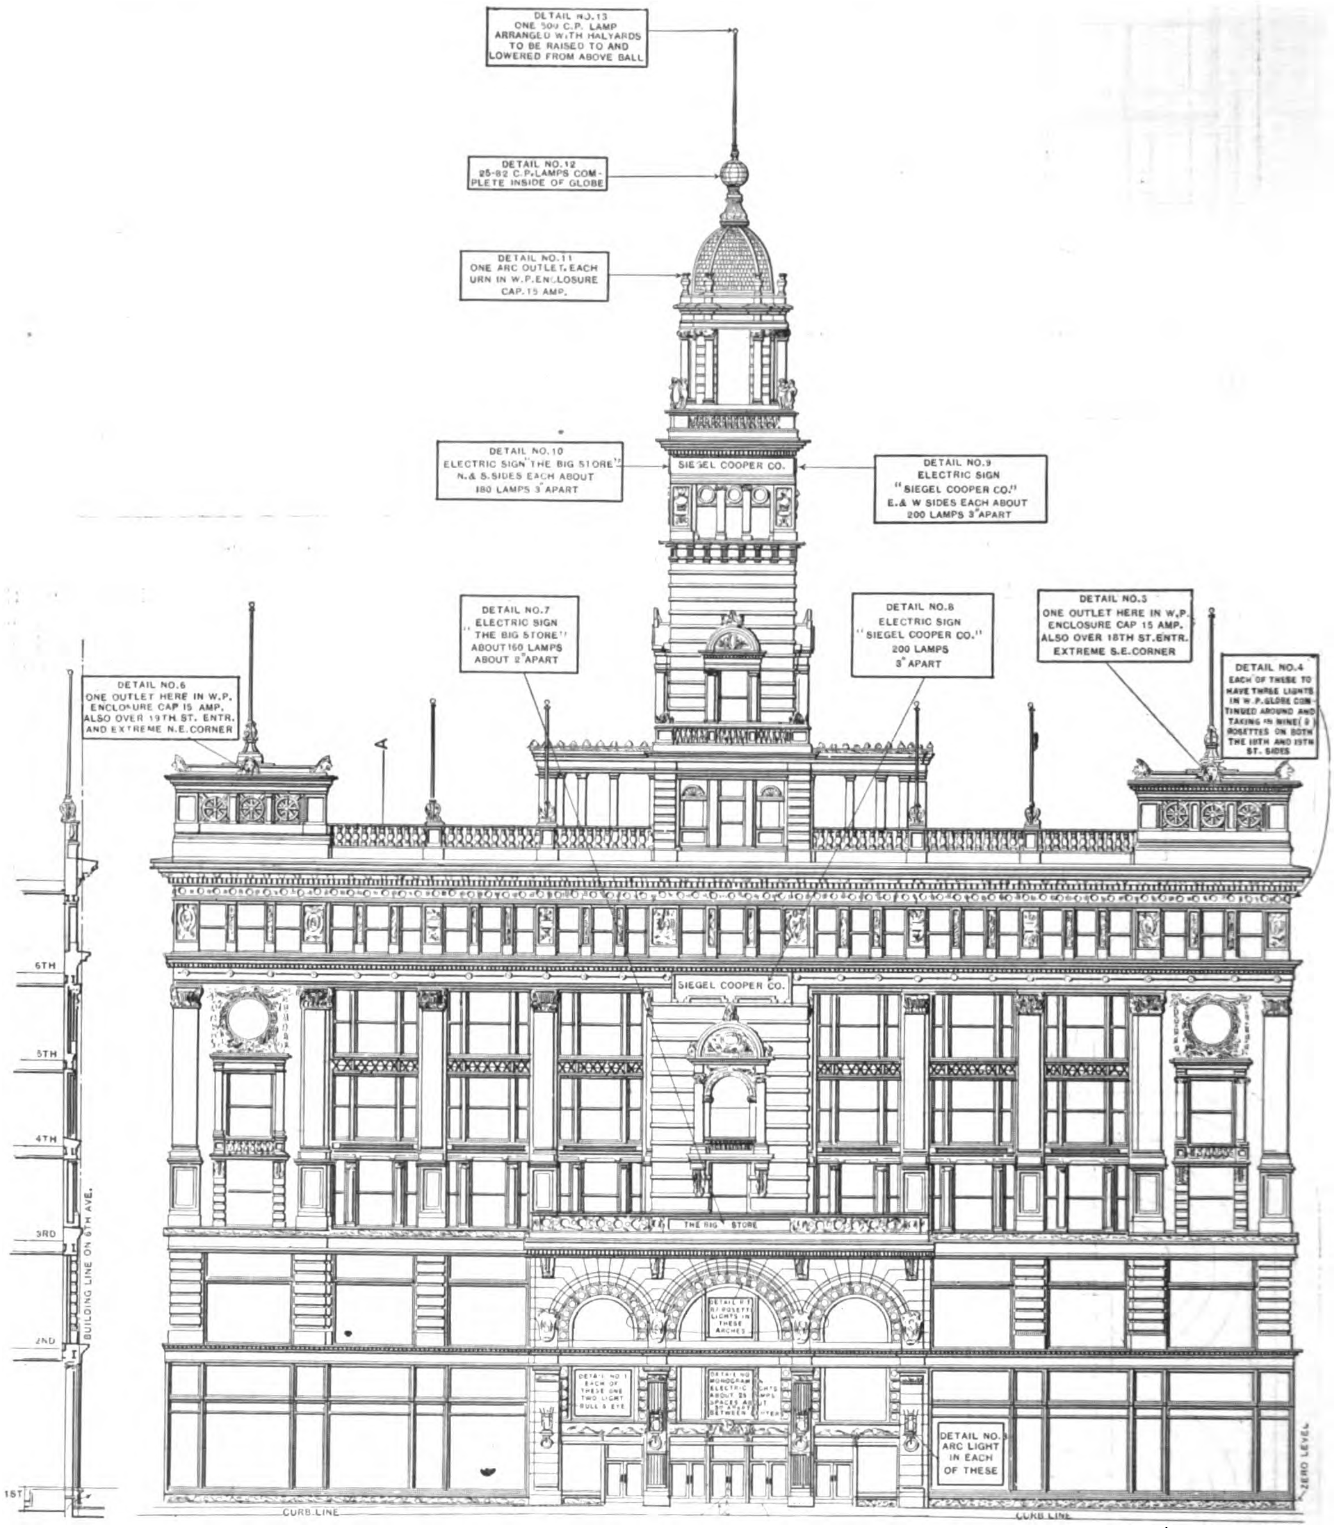

FIG. 6.—THE SIEGEL-COOPER STORE.—FRONT ELEVATION, SHOWING LOCATION OF ELECTRIC SIGNS AND DECORATIONS.

and strong arm, as well as ensuring a good flexible contact for the clips. These switches are being constructed according to the directions of the engineers. There are sixty feeder switches and eight dynamo switches provided, besides those for the voltmeter and field circuits, while provision is being made, as already stated, for connecting another dynamo to the switchboard.

overhead track is being erected. This track will be capable of sustaining a load of five tons, and will be completely equipped with differential pulley blocks, gears and turntables, with ball bearings throughout, one of these latter being located between each pair of units and arranged so that hoists can be run directly over either the engne or dynamo, the damaged part lifted up and carried to the engineers' machine shop, where

the necessary repairs or alterations can be made. This machine shop is to be equipped with all the latest and best apparatus, such as lathes, milling machine, drills, forges, etc., these being operated by a 10 horse-power motor.

Current is distributed to no less than 120 miles of circuit, for which Habirshaw wire, made by the India Rubber and Gutta Percha Insulating Company, is used; for all circuits carrying not more than 100 amperes, duplex cable is run, and owing to the length of the runs some of these cables have to be of 250,000 c. m. area. The conductors range in size from No. 14 to 3,950,000 c. m., all being stranded; these wires are run throughout in "Interior" iron armored conduit, in sizes from ⅝-inch up to and including 3-inch.

The wiring is figured for a 4 per cent. drop from switchboard to the farthest light, allowing 3 per cent. loss on the feeders, 1 per cent. on the mains, and 1 per cent. on the branches, thus having but 1 per cent. variation between any two lamps. Each floor has two sets of feeders, one each on

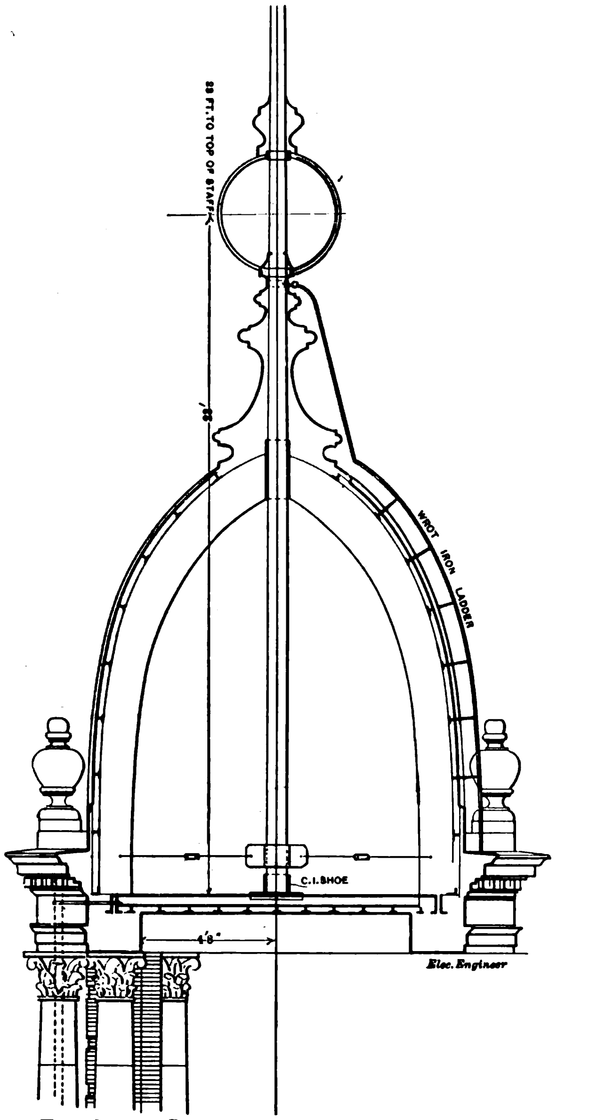

FIG. 7.—THE SIEGEL-COOPER BUILDING.—SECTION OF DOME.

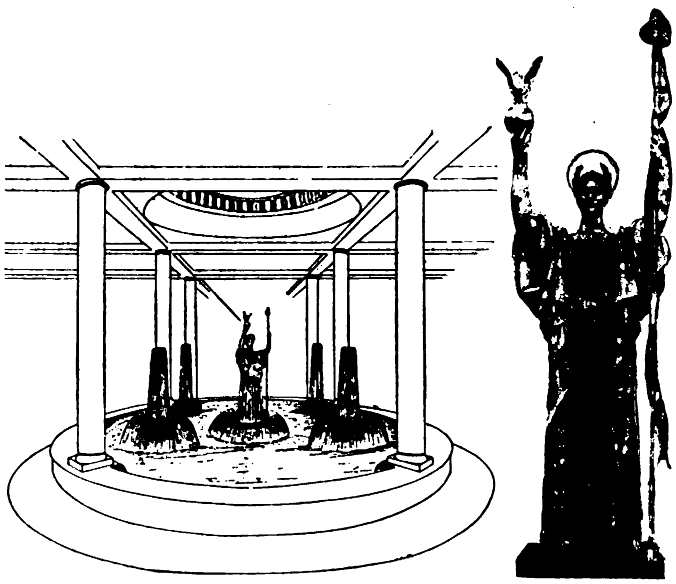
the Eighteenth and Nineteenth street sides, separate feeders being provided for arcs and incandescents. One difficult and unusual piece of conduiting is shown in Fig. 5.

The dynamo feeders are installed for one-quarter of 1 per cent. drop, necessitating wire from 2,225,000 c. m. up to over 4,000,000. They are carried in trenches on porcelain bridges under the dynamo room floor. Each run is of single cable instead of the usual combination of several small ones to get the ampere capacity.

Within the store, as might be expected, the lighting will not only be brilliant, but there will be various special effects. We illustrate herewith a few of the fixtures for the incandescent lighting, Figs. 12, 13 and 14. The arc lamps will be those of the Marks inclosed type, known as the Pioneer, the cases being from designs by the engineers. The selection was made after a very severe competitive test, and each lamp is guaranteed to run 100 hours without new carbons. It will readily be understood that inclosed arcs are peculiarly desirable for the interior of a large store of this character.

The inclosed arcs are of the standard 4½-ampere type. Each of the large ornamental lanterns in front of the building will be furnished with lamps from which the large globe has been removed. When a greater volume of light is desired, the outer globe of these lamps is removed, the light then emanating directly from the small opalescent inclosing bulb. This feature of the lamp makes it especially valuable in show windows, for which it will have extensive use in this building; although there is no outer globe on the lamp it is impossible for any spark or carbon dust to escape from the bulb and injure merchandise below the lamp.

With few exceptions, all indoor lamps for this building will be of special design, the coverings, having been designed to match the other decorations. In the conservatory there will be twenty-six special lamps, provided with green-tinted globes specially adapted for the illumination of this part of the building. In the photograph gallery there will be six special focusing lamps adapted for this particular work. These lamps will be of the type now largely used in the leading universities of the country for stereopticon light and photographic purposes, and will require no lamp mechanism other than a rack rod and thumb screw for their operation.



FIGS. 10 AND 11.—THE ELECTRIC FOUNTAIN AND STATUE OF THE REPUBLIC.

Perhaps one of the most important points in connection with the electrical design of these lamps lies in the perfect regulation of the mechanism throughout the range of the lamp; this regulation permits of successfully operating the lamp through a wide range of voltage, so that if the potential of a circuit varies, even as much as ten per cent., there is no resulting unsteadiness in the light.

Reference has been made above to the lighting in bulk. The cut, Fig. 6, shows in graphic detail just what use will be made of lights on the fronts of the building, while Figs. 7 and 8 give some interesting details of the dome, which is not only a lantern in itself and a support for the lamp-studded flagstaff, but will carry a traveling "search," as shown in Fig. 8, which will be arranged to revolve around the tower, stopping for any desired length of time, with its beam pointing in any direction. This search will be used for signalling election returns and any other matter of general interest, as well as the weather reports and predictions, which will be indicated at night for the day following. It is also intended to project the beam on clouds, etc., and by means of different slides indicate to prospective bargain hunters when a special sale will take place.

At the extreme top of the flagstaff, as mentioned above, will be mounted a 500 c. p. incandescent lamp, which will be arranged to raise and lower by means of halyards.

The sphere shown just below the flagstaff will be built of a framework of iron and diamond cut crystals, inside of which will be mounted incandescent lamps.

Fig. 6 illustrates very clearly the disposition of the various electrical signs around the building and also indicates in minute detail the location of the cluster lights along the cornices

and within the arches of the main entrances. These signs will be constructed in an entirely waterproof manner and all connections and woodwork entering into their construction will be inclosed in a copper casing which will be gilded and highly finished. These signs will be supported on the walls by means of expansion bolts with the connections entering the letters directly form the back. They will thus stand out in bold relief with no unsightly iron work to mar their appearance.

On the first floor, Fig. 9, at the foot of the grand stairway, will be seen, close to the elevator shaft, a space in which will be a superb electric fountain, Fig. 10. This point is practically the center of the store, and visible from every part. It will have a huge basin of marble forty-four feet in diameter. At the center of this basin will stand a replica, in bronze, of French's heroic statue of the Republic, Fig. 11, the same as was seen in the Grand Court of Honor at the World's Fair, rising here to a height of thirteen feet. During the day, when sunshine is flooding the store, the figure will be set off by the spray and by foliage plants, but at night incandescent lamps will twinkle in the dome over the head of the goddess, while from around her feet will burst streams of living color, caused by masked arc lights and moving screens. A preliminary sketch of this fountain is shown in Fig. 10.

The use of electricity for power purposes in this building will be quite notable. Motors are to be applied to a great variety of uses in ventilating, laundry work, machine shop, cash carrier system, etc.

One of the most extensive and varied contracts for elevators, and important as illustrating the rapid advance of the use of electricity in this important service, is that for the elevators. Fig. 9. These elevators have been built by the Sprague Electric Elevator Company of New York City; the size and capacity of some being most unusual. The type of machine which was selected by the engineers for most of the work is that known as type "Z," which is a tandem worm gear drum machine commonly used where large lifts and low speeds are required. The drum is driven by two worm wheels and right and left handed worms with interlocking spur gears. The worm wheels are of bronze, cut by the Hindley method, and are each carried on a bisected machine-cut spur gear. The worm wheels run clear of each other, and the shafts are interlocked by spur gearing. The worms are of steel, right and

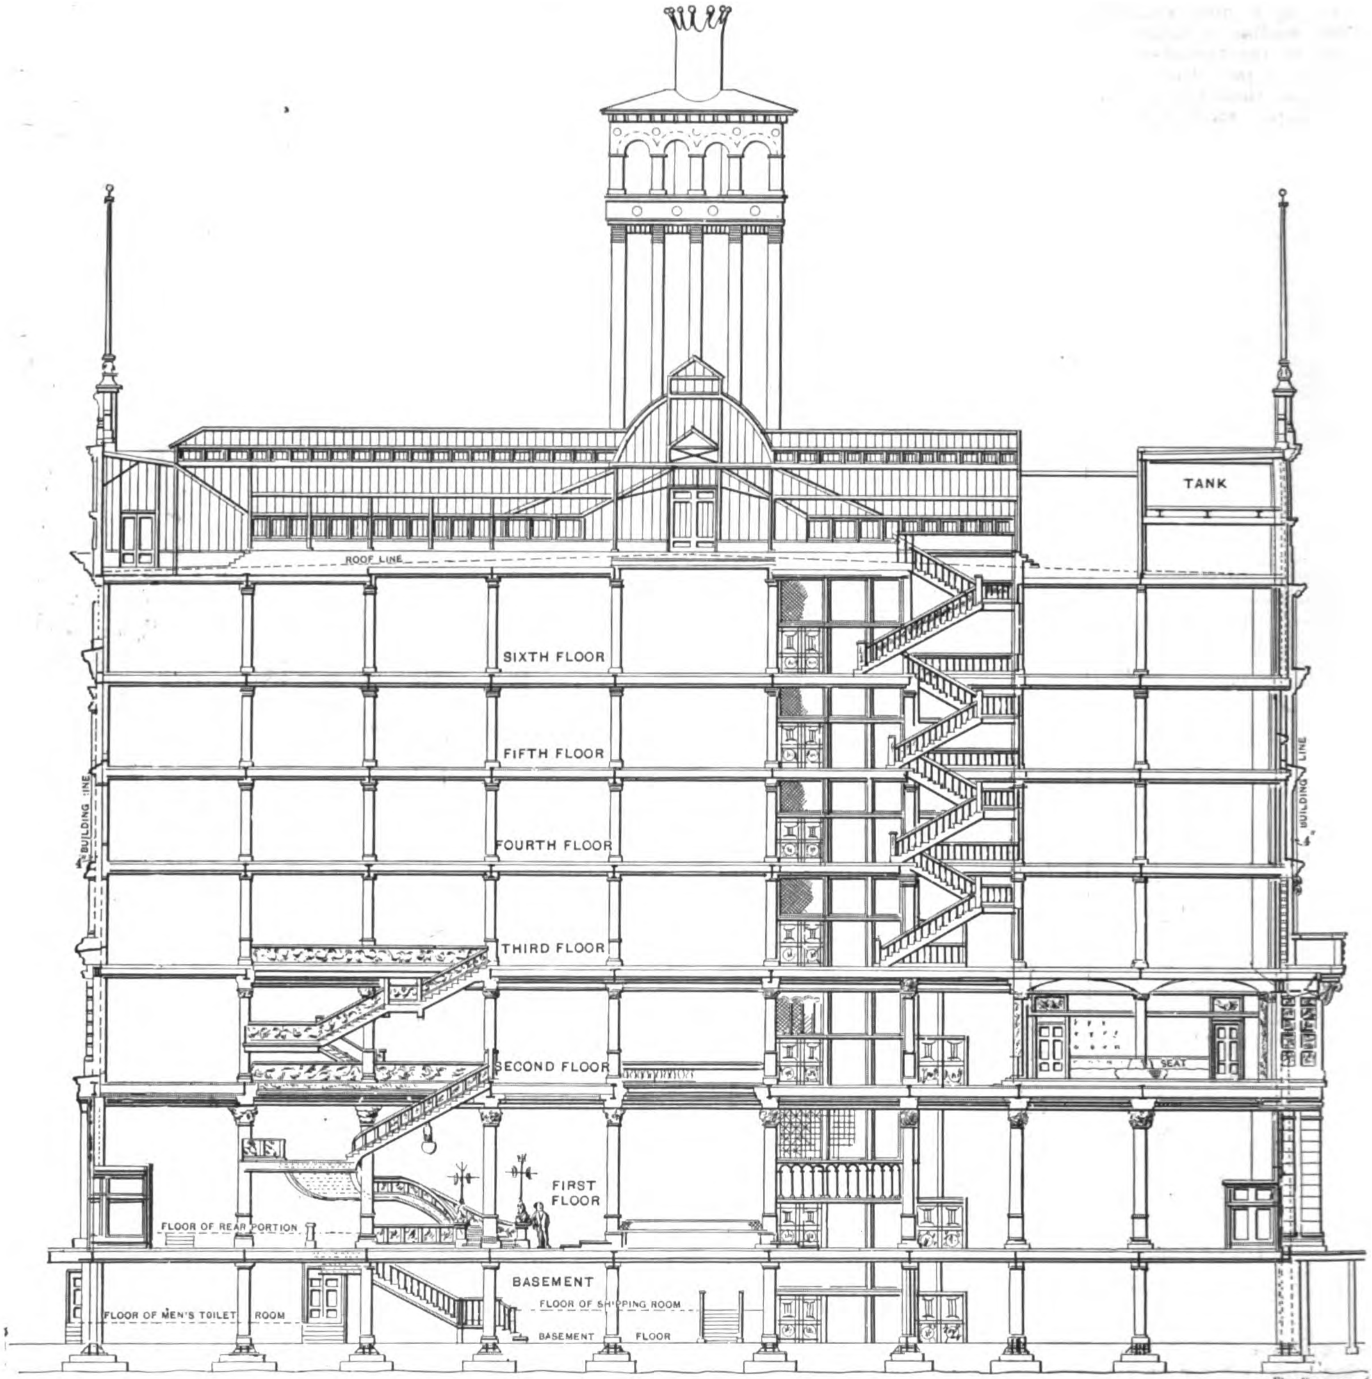


FIG. 9.—THE SIEGEL-COOPER STORE.—SECTION OF BUILDING.

left hand cut, have double pitch and an enormous bearing surface. The worm and spur gears all run in the same gear case and in oil. All the machines are electrically controlled with automatic car controlling switches, and the rheostats are

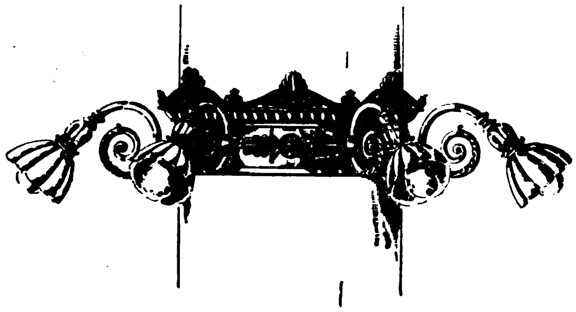

FIG. 12.—A COLUMN BRACKET ELECTROLIER.

operated by pilot motors. The "up" and "down" limit switches are double, the circuit coils being open circuited and on their failure the main circuit operates independently.

The elevator details are as follows: 1. Sidewalk elevator, restaurant platform, 3 feet by 4 feet 6 inches; rise, 13 feet; speed, 60 feet; capacity, 1,200 pounds. 2. Three sidewalk elevators, shipping department to sidewalk, platforms 3 feet 6 inches by 10 feet; rise, 10 feet and 17 feet; speed, 80 feet; capacity, 1,500 pounds. 3. Furniture elevator, basement to sixth floor, platform 12 feet by 16 feet; rise, 95 feet; capacity, 5,500 pounds; speed, 200 feet a minute with 4,000-pound load. Arranged for an additional rise of 30 feet. 4. Three freight elevators, two being from shipping department to sixth floor, rise, 95 feet. One from sub-cellar to roof, 120 feet. Platforms, 10 feet 6 inches by 11 feet; capacity, 5,500 pounds; speed, 200 feet a minute with 4,000-pound load. Arranged for an additional rise of 30 feet each. 5. Two employés' elevators, from first to sixth floor, rise, 86 feet; platforms, 11 feet by 11 feet; lifting capacity, 5,500 pounds; speed, 200 feet a minute with 4,000 pounds. Also arranged for an additional rise. 6. Eight passenger elevators, from basement to sixth floor, rise 100 feet; platforms, 8 feet by 8 feet; speed, 200 feet a minute with 4,000 pounds. 7. Two passenger elevators, from first to sixth floor,

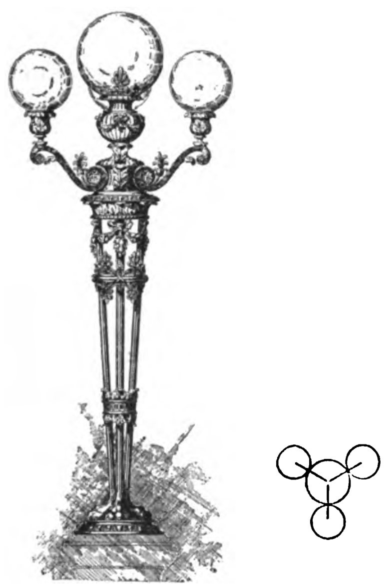

FIG. 13.—A NEWEL POST ELECTROLIER.

rise, 96 feet; platforms, about 5 feet by 6 feet; speed, 250 feet with 2,500 pounds load. 8. One baggage elevator, from basement to sixth floor, platform, 3 feet by 6 feet; speed, 250 feet with 1,200 pounds.

All the motors are self-oiling, and the armature speed is limited to 800 revolutions per minute. The armatures are of the iron clad type. The machines are operated by a special power circuit chiefly at a 240 volts potential.

The building will be equipped with the American Watchman's Clock, and as at present arranged and designed by the engineers, this will consist of a 45-station clock with the necessary dials, etc., connected with key operated stations located through the building in such a manner that the watchman can be made to follow any course desired.

Standard time will be maintained throughout the building by a system of electric clocks, connected to a main regulator located in the principal offices.

The building will be equipped throughout with a fire alarm system indicating on annunciators placed in the engine room and principal offices, and ringing bells located in various parts of each floor. These bells will be arranged to ring for any length of time by regulating an automatic on the engine room annunciator.

Inter-communicating telephones will be arranged and connected so that conversation can be carried on between any points in the building without the use of a central.

A small subsidiary storage battery will be used to furnish current to the watchman's clock, electric time, fire alarm and telephone systems. These systems are of unique design and were carefully laid out by the engineers.

The "Big Store" will also exemplify many other uses of electricity besides those already enumerated above. Electric heaters, for example, are to be employed in the laundry and drying rooms and other places. On the roof there will be a photographic gallery, equipped with the latest pattern focusing lamps, enabling the photographers to go right on regardless of the weather or the hour. Not far away, also on the roof, will be a beautiful conservatory and florist's shop, with all manner of fairyland effects from lamps hidden in flowers and foliage.

The fixtures include about 500 fixtures from one to fifteen lights, and over 1,900 pendant single lights, etc. Many of the larger pieces are very fine. The clusters are to be of the separable type, facilitating the use of 10, 15 and 18 inch porcelain

FIG. 14.—A THREE-LIGHT WALL BRACKET, LADIES' PARLOR.

shades. Some of the styles are shown, as already stated, in Figs. 12, 13 and 14. The newel post fixtures are in rich gilt finish. The column fixtures on the first floor are in Renaissance design, very elaborate and richly gilt.

In the barber shop, café, restaurant, etc., they are slightly less ornate, and silver plated, with the brackets and ceiling fixtures to match. In the ladies' parlor, the Empire style prevails, with all the fixtures heavily gold plated. At the entrance to the building there are solid bronze octagonal glass lanterns of Renaissance design, containing band arc lamps. These are an almost exact reproduction of some famous Italian lantern designs.

Steam for the engines and for heating the building will be obtained from ten boilers of the horizontal return tubular type, 6 feet 6 inches by 18 feet, built by Messrs. Samuel Smith & Son, of Paterson, N. J. The feed-water will be heated by a Berryman heater and filtered by the Ward filter built by Messrs. Ward & Anderson. Some idea of the extent of the steam will be conveyed by the size of the exhaust steam pipe which is 18 inches in diameter. The Locke damper regulator is employed and all steam pipes are covered with the Keasbey sectional covering.

The ventilation of the basement and first floor will be effected by means of eight Sturtevant blowers and exhaust fans, each 8 feet diameter of wheel, and the temperature will be regulated by the Johnson heat regulating system. The conservatory on the roof will be heated by a separate hot water system. The "Big Store" will be opened for business September 1, this year, by which time the plant will have been in operation about one month, and no doubt through the courtesy of the Alexander-Chamberlain Electric Company, the readers of this paper will be given an opportunity to inspect this most interesting and modern plant.

THE WORCESTER AND GLOUCESTER, MASS., CENTRAL STATIONS.

An excellent representative of modern electric lighting and power station practice is to be found in the Worcester Electric Light Company, of Worcester, Mass., where some of the latest ideas in station construction and practice have been put into operation.

The station has been built about one mile from the center of distribution in the town, on the banks of a small stream, which furnishes a supply of water for condensing purposes. The engines are of the Geo. H. Corliss type, having an aggregate of 2,500 horse-power. These are placed on the lower story and are belted to the line shafts in such a manner that any engine can drive any shaft or part of a shaft, as may be required. The belts from the line shafting pulleys pass through the floor to the half story carrying the dynamos, and any belt can be thrown on or off any dynamo pulley at will, the handles being placed beside each dynamo, as shown in the accompanying engraving, Fig. 1.

The arc lighting plant consists of twelve 50-light and four 30-light Thomson-Houston arc machines, each light being rated at 2,000 candle-power. The incandescent plant comprises three 2,000 light and one 1,000 light, 1,000 volt Thomson alternators, while the power portion of the station consists of three G. E. 500 volt multipolar generators, two of 100 kilowatts and one of 200 kilowatts.

The offices and repair shop are located in the second story, the repair shop being arranged to take care of all ordinary repairs on the engines, boilers, shafts, dynamos and lamps.

In the construction of the station the plans of Mr. W. H. Coughlin, the general manager, have been followed out, and the excellence of these and the substantial character of the station will be appreciated from the fact that a lower rate of insurance is charged upon the Worcester station than upon any other electric station in New England.

The lines are at present all overhead, but since last year the company have been laying conduit through the main streets, and during the coming year expect to have the greater portion of their wires in the center of the city placed underground in these conduits. General Electric apparatus is exclusively employed both in the station and streets.

The Worcester Electric Light Company is capitalized at $300,000 stock and bonds. According to the Gas Commissioner's report, the income of the company in 1895 was $136,000, and the operating expenses, $73,000. The net earnings thus show the creditable total of $63,000. The officers are: Thomas M. Rogers, president; H. H. Fairbanks, treasurer; and W. H. Coughlin, general manager; the supervision of the business being in the hands of Messrs. Coughlin and Fairbanks.

Another interesting New England station is that of the Gloucester, Mass., Electric Light Company, rebuilt some six years ago. The present power house is of brick, 100 feet by 50 feet, divided into engine room and boiler room. The building backs on the harbor and has a wharf with docks on each side facilitating the handling of coal. Salt water is used for condensing purposes.

Fig. 1.—The Worcester, Mass., Electric Light Station.

The boiler room contains three horizontal Roberts & Company boilers, each with a capacity of 125 horse-power. The engine and dynamo room, shown in Fig. 2, contains two 250 horse-power McIntosh & Seymour compound condensing high-speed engines, connected to a central shaft so that the dynamos can be operated from either or both engines. The generating plant consists of three 50 light 1,200 c. p. T.-H. arc machines, one 1,300 light T.-H. 1,000 volt alternator, and one 150 kilowatt G. E. monocyclic machine wound for 2,000 volts. In addition to these there are two G. E. 100 kilowatt, 500 volt multipolar generators for power work. The wires from the machines are led to a cage in the monitor room, and are then connected to the different circuits. This method greatly facilitates handling and changes. The switchboard is of the skeleton type readily reached from all sides.

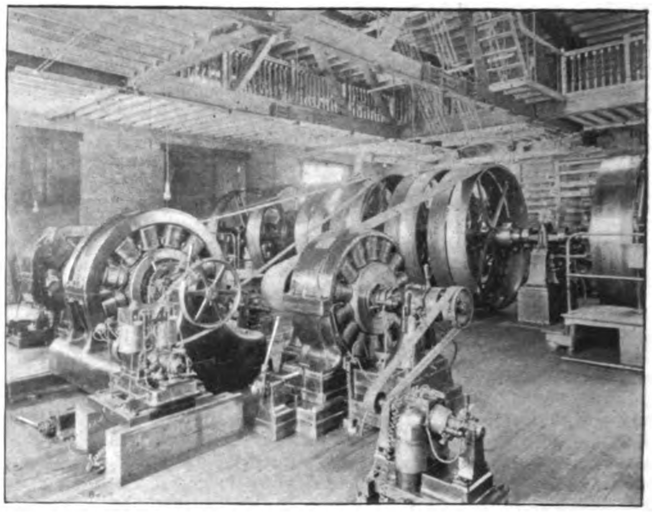

Fig. 2.—The Gloucester, Mass., Electric Light Station.

This company furnishes light and power not only to Gloucester, but also to Magnolia and Rockport. The power demand is very large and the station runs twenty-four hours daily. Magnolia and Rockport are each about five miles distant from Gloucester, and the lights and motors in these two towns draw their supply of current from the monocyclic machine.

The president of the Gloucester Electric Company is Mr. W. H. Jordan, of Boston; E. W. Norris, treasurer; Ernest L. Munger, superintendent and electrician.

FILAMENTS VIBRATING UNDER THE INFLUENCE OF A MAGNET.

LEO DAFT.

In The Electrical Engineer of March 25 there is mentioned an experiment made some weeks previously by Sir David Salomons, in which the filaments of incandescent lamps served by alternating current were made to vibrate, and finally tear themselves from the connections, by gradual introduction to the field of a continuously excited magnet. Since this paragraph has been going the rounds of the papers, I thought it might not be amiss to mention the fact that I used the same experiment in lectures at the Plymouth Congregational Church, Seattle, on the evening of February 13, 1894, and on two other occasions within the month following, during which time it was seen by at least three thousand persons.

I used a magnet with cores 5 inches in diameter, which will support from eight to ten thousand pounds when well excited, and with this the filaments began to vibrate perceptibly at distances of several feet, and were generally torn apart when within eighteen or twenty inches of the poles.

I found it a capital lecture experiment, and when made with a 50 c.-p. lamp was effectively shown to a large audience.

ANOTHER BATTERY STATION FOR BOSTON.

The Edison Electric Illuminating Company, of Boston, has made arrangements for a storage battery plant in the Back Bay, west of Massachusetts avenue. It will be a brick building, considerably larger than its present storage battery plant on Head place, and will be used as an auxiliary to supply the eastern part of the Back Bay district, and will furnish all the current for the western, or newer, part. It will be supplied from surplus current generated at the Head place and Atlantic avenue power stations. This move on the part of the company is interesting as a proof of success of the storage battery system, and contains a hint of how a station may be placed in a residential district without creating the objections of manufacturing directly by the use of steam.

HIGH VOLTAGE LAMPS AND THEIR INFLUENCE IN CENTRAL STATION PRACTICE.—IV.

BY G. L. ADDENBROOKE, M. I. E. E.

I MAY say that Mr. Crompton objects to the method of taking the consumption per 8 c.-p. lamp installed as a basis of comparison, and I quite agree that it is rough and unscientific; and it might be well if our friend the editor of "Lightning" would look into it, and see if he could not get a sounder basis for comparison. Mr. Crompton suggests the relation between the annual output in B. T. units, and the output which would be registered if the maximum load were continued day and night throughout the year. In this case he tells me the actual output would vary from the equivalent of full load for 700 hours in some country towns to 1,000 in parts of London, 1,300 in Kensington, and a much higher figure for the Pall Mall and St. James's Company. Thirteen hundred hours corresponds to a load-factor of 15 per cent.; though it will readily be seen that it is a figure of more comprehensive nature, and not exactly similar. I leave this question here, however, as, though very interesting, to discuss it further now would be out of place in this paper. In order to complete the comparison made above, the cost of insulating and of laying the cables should, of course, be taken into consideration. In order to set this point at rest, Mr. T. O. Callender has kindly prepared for me data deduced from their experience in supplying and laying cables, which, as a result of a large amount of practice, are beyond cavil, and which show the average cost of cables laid as compared with the cost of the copper in them. These particulars are given in the following Table II.:

TABLE II.

TABLE SHOWING THE TOTAL COST OF INSULATED CABLES LAID COMPLETE AS COMPARED WITH THE COST OF THE COPPER CONTAINED.

Character of Cables (Separate).	Armored, laid direct.	Plain, laid in solid bitumen.	Armored, laid direct.	Plain, laid in solid bitumen.
	Sq. inch.	Sq. inch.	Sq. inch.	Sq. inch.
Area of cable: Outer	0.50	0.50	1.00	1.00
Area of cable: Middle	0.25	0.25	0.50	0.50
Area of cable: Outer	0.50	0.50	1.00	1.00
Cost of cable laid complete, exclusive of excavation	19s. per yd., £1,650 per mile.	25s. per yd., £2,200 per mile.	33s. per yd., £2,900 per mile.	42s. per yd., £3,700 per mile.
Excavation, cheap streets and lanes	s. 1 d. 3	s. 1 d. 3	s. 1 d. 3	s. 1 d. 3
Excavation per yard, average run of trench in towns under macadam or pavement	2 0	2 0	2 0	2 0
Ratio of cost of copper (at 7d. per lb.) to cost of complete cable laid, as 1	2.5	3.1	2.2	2.3

Under asphalt or wood the cost of excavation will run up to as much as 15s. per yard run, but this item will practically be the same whatever system is used. Moreover, as only a few of the main streets in large towns are so paved, this item is not one which need concern us particularly in a general comparison, but must be dealt with in accordance with local circumstances in each case. It will be noticed in the above table the middle wire is half the section of the outers; in practice it would not be necessary to have this more than one-fifth for the feeders, and in some cases it might be omitted entirely. The actual cost of feeders should therefore come out about 10 per cent. under the prices given, though I have thought better to leave the table as it was, preserving Mr. Callender's own figures.

At these rates, for a two-mile feeder of armored cable, working at a current density of 250 amperes per square inch, the cost, laid complete, would be about £55 per kilowatt for the maximum output; the fall of pressure being about 10 per cent. I think, therefore, that the whole distributing system—consisting of feeders, branches, local services, service boxes, and every other item, also providing for a fair proportion of the cables being laid under asphalt or wood, from such a station as I have described above, with a service extending 2½ miles in all directions—could be laid complete for £60 per kilowatt.

This is a very moderate figure as compared with the sums now spent. If we assume that 8 per cent. is required to meet interest, upkeep, and depreciation on this outlay, and if we take the output of the station at 800 kilowatt-hours maximum load on the basis suggested by Mr. Crompton, it is evident that interest and upkeep on the distributing system would cost about 1½d. per unit of current sold for the whole distributing system; so that a charge of 1½d. per unit would cover all costs outside the station itself. From what we know of the cost of generating electric energy, it will, I think, thus be clear that, even in places where coal was expensive, a very good profit would be made by selling current at 4d. per unit for lighting, and 2½d. for power purposes. In making this calculation I have assumed the same density of population over the whole area; but it is evident that this would very seldom be the case, as in nearly all towns at two miles from the center the density of population is greatly reduced, which would mean a smaller proportion of long feeders, and consequently a less average cost per kilowatt output than I have taken.

I do not wish it to be assumed from what I have said above that the capital cost of a direct-supply station at 220 volts, with feeders and distributing system extending 2½ miles, as described above, would be as low as that for an alternating station at 2,000 volts, with transformers and 220-volt lamps, to cover the same area. It would not. Comparing feeders, I think, with the present prices of mains, and using the same class of insulation in each case (as is frequently done now)—that is, not using expensive rubber cables for the high tension—the two systems are equal in cost for feeders 1½ miles long. As the distributing system will extend a quarter of a mile further beyond the end of each feeder, a direct-supply station on exactly the same lines is as cheap in capital cost for an area having a base of at least 3½ miles and covering 10 square miles. Further, as something must be allowed to the direct-supply system on account of lower depreciation, and greater safety and freedom from restrictions, and ability to supply motors more easily, another quarter of a mile may easily be allowed on the feeders of the direct-supply station on this account; so that the systems compare together when the base of the area served is four miles and the area itself 16 square miles, even if no accumulators are used.

Although this is not as large as the area I have taken as a basis, what it means can be estimated from what has been said above as to the actual areas covered by large towns. I am, of course, assuming that 220-volt lamps are used on the transformer station as well as the direct. If we assume that the transformer station employs 100-volt lamps, of course the comparison would be much more decidedly in favor of the direct supply at 220 volts.

There is no need, however, to go very minutely into these figures, because, though thoroughly practical, they do not represent what it is clear will be central station practice in the future, as I do not think it probable that any direct-supply station in the future will be operated without accumulators.

The Use of Accumulators.—This brings me to the fifth and last point mentioned at the beginning of my paper when enumerating the possibilities likely to affect central station practice in the future, viz., the use of accumulators. In the earlier part of 1891 I did not see much likelihood of improvements in accumulators making any really fundamental alteration in central station practice. But I must confess that in this respect events moved faster than I anticipated, although I have been brought sufficiently into contact with them to learn what was going on in the field and how batteries were doing as regards upkeep. Up till comparatively recently there is no doubt accumulators have been rather a luxury and convenience in central stations than a commercial or economical necessity; but during the last two or three years considerable changes have been taking place. The maximum safe discharge rate for accumulators has been going up, while the initial cost has been going down, as well as the cost of upkeep, and extended experience holds out the hope of much longer life for the newer and improved forms of positive plates than has hitherto been the rule. Owing also to the method of supplying accumulators at a maintenance rate adopted by the leading firms, an engineer need have less hesitation in recommending clients to incur a large expenditure on them, and the risk is much less than formerly. Patents are also expiring, and considerable competition is arising in this trade, which was formerly such a close one.

I have lately had to make careful inquiries about accumulators in connection with work on which I am engaged, not only as regards prices, but also as to their working, and, having got particulars about the batteries in several central stations, and held conversations with the engineers concerning them, have been considerably surprised at the progress which has been made. Taking quotations from leading makers for a battery suitable for a central station, I find that the capital cost of a battery to discharge at 1 kilowatt for three hours is as nearly as possible £13 for the battery alone. Several makers assure me that such a battery can be discharged at this, and even higher rates, every day regularly, without detriment or endangering the life of the positive plates. The above price does not include buildings to contain the accumulators, connections, instruments, or stands to hold them, which bring up the cost to about £19 per kilowatt on this basis for central station batteries. The makers tell me further that they are willing to enter into contracts to maintain such batteries in a state equal to new for about 6 per cent. per annum on their capital cost, and

some makers will even go lower than this. It will be found that these costs and rates of renewal are a great improvement on those ruling until comparatively recently.

Now I should not quote these figures unless I had, by private inquiries and in other ways, fairly convinced myself of their substantial accuracy. Granting that they are so, it appears to me that they raise questions of very serious import in central station practice, particularly when coupled with the use of higher voltage lamps. If an accumulator will give a discharge for three hours—that is, sufficient to cover the period of heavy load, or the time during which the large portion of the plant has to be kept running—a kilowatt capacity of accumulators will be equivalent to a kilowatt capacity in engines and dynamos. In continuous-current stations, when an increase of output is required—which is from time to time the position of most stations—we are therefore brought face to face with this problem. Extra plant for 200 kilowatts output, say, is required. Which is the best way of providing for it—by adding engines and boilers, or by adding accumulators and charging them during off hours from the existing plant? Now, as I have said above, an accumulator for an extra kilowatt output will cost about £19 complete and erected, including buildings; and I think engineers will generally agree with me that engines, boilers, dynamos and steam pipes for a kilowatt output, including buildings and all other accessories, would cost about the same sum; if foundations, flues, chimney stack and everything else were considered, the comparison would be slightly in favor of accumulators. However, for our present purpose, let us assume that they are equal. We have therefore arrived at the position that the capital cost will be equal, whether we provide extra plant or extra accumulators for the increased output required, charging the accumulators from the existing plant. As regards upkeep, if we can keep the accumulators in an efficient state for 6 per cent. on their cost, this is not greatly in excess of what would have to be allowed on plant if boilers are included; and, at any rate, the difference is not a matter of very great moment.

There is no need to say anything here on the extremely low cost at which energy can be produced if a continuous load is provided night and day. Considering the advantages accumulators give in a central station in providing for emergencies, reducing staff, and keeping the pressure even, it is, I think, doubtful if an engineer placed in the position indicated above—as many engineers will be placed shortly—would not be wise in recommending his corporation or his board to install accumulators for 200 kilowatts output for three hours, instead of the extra plant, when the plant was a continuous one. How far this should proceed is a moot point, dependent upon circumstances, which would need decision in each case. Possibly somewhere about one-third the maximum full-load capacity would be about right now, but with a load-factor of 10 to 15—which is about that general in central stations—if the price of accumulators came down per kilowatt output, which I think it is likely to do in the future, or their efficiency increased, it might be found desirable to install accumulators for as much as two-thirds, or even three-fourths, of the full load, which would place electric distribution nearly on a par with gas distribution in respect to storage. To go as far as that is, however, not a question of the present—at any rate in most cases—and therefore for our purpose this evening I propose to consider the accumulators as desirable for about one-third to one-half the full output.

THE GAS ENGINE AND ITS ELECTRICAL APPLICATIONS.

IN the above entitled paper read by Mr. Charles Macdonald, M. E., before the Chicago Electrical Association, the gas engine of the future was defined as one so designed that its gases could be expanded down to atmospheric pressure. More of the heat that is lost through the walls of the cylinder and out through the exhaust port should be utilized. In governing the engine, the gas and air should be reduced in the proper proportion so as to make always a combustible mixture. The engine should be designed so that its motion can be reversed. It should also be made single and double acting. The gas producing apparatus should be developed so as to have a cheaper gas.

Mr. Macdonald showed that the further introduction of the gas engine depends very greatly on the development of the gas producing apparatus, which of late has made some advances. Heretofore illuminating gas has always been used. The vogue of producer gas has been retarded by its inferiority to illuminating gas in heating power, and its objectionable tendency to gum the cylinder. The single cycle gas engine is showing up, and has already come into public use. While it has many advantages, it has a very low economy. This is due to the charge being too greatly adulterated with burned and inert gases, or to the loss of gas by its following the burned gases out through the exhaust port when too much air and gas are allowed to enter the cylinder. This was well demonstrated in the motocycle tests recently made in Chicago.

Mr. Macdonald held that it was only a matter of time when the mechanical difficulties in the gas engine would be overcome, its efficiency greatly increased and its mechanism made as perfect as that of the steam engine. High smokestacks and boilers would then be relegated to the background, the firebox would be converted into a motor cylinder and the city population would no longer breathe air contaminated by smoke. The cost of production and transmission of power would be reduced to a minimum; the lower strata of society would participate more in the luxuries of life and civilization will have taken another gigantic stride.

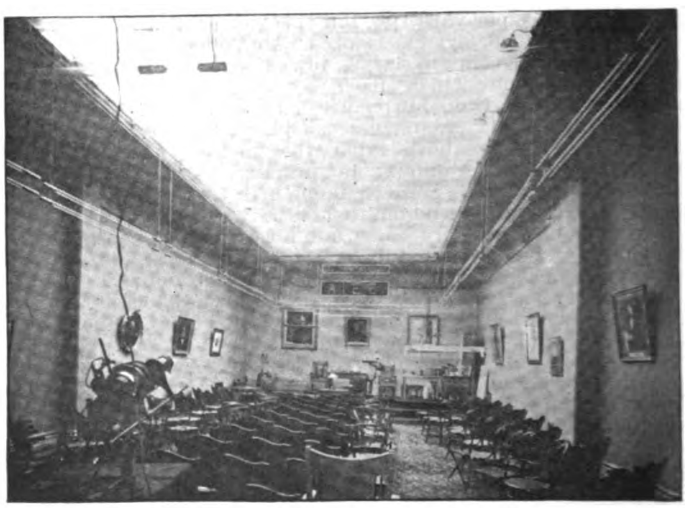
THE FIRST HALL LIGHTED BY VACUUM TUBES.

THE paper read by Mr. D. McFarlan Moore before the American Institute of Electrical Engineers has attracted general attention and the figures as to the economy of the lighting, which we published in our last issue, have come as a revelation to electrical engineers, who were hardly prepared for the statement that a vacuum tube giving light enough to read by required no more energy than a 4-watt sixteen candle power incandescent lamp.

D. McFARLAN MOORE.

It is difficult, of course, to convey to those who were not fortunate enough to be present, an idea of the volume of illumination produced by Mr. Moore's twenty-seven vacuum tubes on the evening of his paper, but perhaps the best evidence we could offer is the photograph of the institute meeting hall, which we reproduce on the opposite page, and which was taken with an exposure of only five minutes by the light of the Moore vacuum tubes. A good photograph was also obtained by a 30-second exposure, while a three-minute exposure gave quite as good a result as the one we illustrate. The sign A. I. E. E., suspended above the platform, was illuminated during only one minute of the five-minute exposure.

The detail and even tone of the photograph leave nothing to



THE A. I. E. E. MEETING HALL WITH MOORE'S VACUUM TUBES. DAYLIGHT PICTURE, SHOWING ARRANGEMENT OF TUBES.

be desired, and no better evidence could be submitted as to the volume of light present. The photograph, it need scarcely be said, has not been retouched in the slightest degree.

In order to indicate the exact arrangement of the tubes, we reproduce on this page a daylight picture of the meeting hall.

CONTENTS.

CONVENTION TOPICS.

THE Convention of the National Electric Light Association, assembling as we go to press, will probably be the largest in point of numbers and the most representative in character thus far brought together in the history of the association. The exposition will, of course, do much to attract the members of the association, but we hope that they may find time to devote adequate attention to the papers which are to be read at the convention, some of which merit the most earnest consideration of all interested in the distribution of electricity. The continuance of the exposition for an extended period after the convention is an improvement, of course, over the temporary exhibits which have for a long time formed a feature of these gatherings, and ought to afford members no excuse for neglecting the convention in order to inspect the latest novelties which are usually spread before them by enterprising manufacturers.

The papers of the convention will well bear discussion, but there are other things which the members will probably find it advantageous to dwell upon as topical subjects. To begin with, we believe that an interchange of opinion on the inclosed arc lamp would be eminently timely. This type of lamp, which was first practically shown in operation at the Washington Convention two years ago, is gradually but surely gaining its way in public favor, and those who have not already looked into its workings with a view to its adoption ought to be able to gather valuable information from those who have already taken it up commercially. That the inclosed lamp has come to stay there cannot be the slightest doubt, and in Brooklyn, for instance, where 350 such lamps have been employed in street lighting service, a saving of $15 per lamp per year is reported, while in Boston, where 200 inclosed arc lamps have been in use, burning on an average of 3.64 hours per lamp a day, the Boston Edison Company figure out a saving of from $11 to $12 per lamp per year. In these days of close competition and so-called anti-monopolistic city councils, $15 per lamp per year may mean a difference between a profit and dead loss. To be sure there are still some difficulties in the way of the application of the inclosed arc lamp to series arc circuits, but we believe that even these in time will be removed, so that they will largely replace the open arc, now universally employed.

Perhaps of equal, if not greater, interest to the members as the inclosed arc lamp as a topic of discussion will be the Moore vacuum tube light, which will be practically demonstrated by Mr. Moore in an evening lecture. That the incandescent lamp is not the ultima Thule of illuminants for interior lighting has been admitted by even its staunchest advocates, and it would be strange indeed, if a device of such low efficiency as the present type of even the best incandescent lamps would satisfy the ambition of the inventive and resourceful electrician. The vacuum tube light has long been looked forward to as a solution of the efficiency problem, and Mr. Moore has, without doubt, carried it to a point far beyond that reached by any other worker in this field. If, after but a few months of experimentation, Mr. Moore has succeeded in bringing his lamps up to an efficiency close within the range of that of incandescent lighting, what may we not expect in the next few months? That Mr. Moore's tubes give light, will, we think, no longer be denied after an inspection of the photograph which

we reproduce on another page. It will bear comparison with the best interior, artificially illuminated, which has yet come under our notice. No member of the association can afford to ignore this latest advance in the art, which he may be called upon to apply to his circuits at no very distant day.

At several previous conventions members have given their experiences as to outlets of various kinds for station current. It would be more than rash to say that even the regular applications of heat, light and power had by any means been exhausted as long as the load diagrams of most stations still exhibit the undeniable indications of light load. How to even the load, therefore, may well occupy the convention for a brief space of time. Of course the storage battery is, par excellence, the leveler of load diagrams, and will doubtless find more willing patrons among American central station managers as time passes. But what the live manager is after is some paying load to fill the present gap. We know of no better outlet in this direction for spare current than in the generation of electrical disinfectants on a large scale for the purification of city water supply, or the disinfection of sewerage. Enough has been done to demonstrate the thorough practicability of this method of treatment for these sanitary purposes and the members present at the convention may convince themselves of the efficacy of the plan by a visit to the Woolf live exhibit at the exposition.

We might continue in the same strain, but enough has been said, we believe, to indicate that the attendant at the convention who does not get his money's worth out of it will have only himself to blame.

THE STORAGE BATTERY.

ONE of the features of the electrical exposition will be the operation during a certain brief period each evening of a model of the great Niagara power house and hydraulic tunnel, with current energy derived by wire from the Niagara power house. During the periods when the wires are not available, storage batteries charged at Niagara, will furnish the necessary current. Some may regard these demonstrations as frivolous or spectacular, but granted that they are they still serve to emphasize the means which the electrical engineer has at his command for carrying out a given problem. It will serve to bring prominently before the public the fact, first, that power can be distributed by electricity with a facility and flexibilitynot approached by any other form of energy, while it will help to impress upon central station managers the fact that the storage battery is a large and growing factor in their field of work, and that sooner or later it will have to be given serious consideration, whether the station operate continuous or alternating current. In either case the load is a variable one and if we are to be at all guided by foreign experience, the storage battery is the immediately available means for securing the highest economy in operation. In a paper read by Mr. Charles Blizard, before the Henry Electrical Club, New York, that gentleman quoted one of the officers of the Tudor Company as the authority for the statement that that company's eight years' experience in German central station practice indicated that the use of storage batteries insured a reduction of 33⅓ per cent. in the engine and boiler capacity and a saving of from 20 to 50 per cent. in the coal consumption of a station. Making all due allowances for this statement as coming from an interested party, the fact remains that in October, 1895, there were 139 central stations in Germany delivering continuous current only, of which 101, or 73 per cent., were equipped with storage batteries. Throughout the continent of Europe and in England the storage battery has been applied with good effect, supplementing the judgment of German electrical engineers. We are glad to believe that our own central station men are evincing an increasing desire to know more about this type of station equipment. The Boston Edison Company was the first to take up the subject on a large scale, and now with the New York, the Brooklyn and the Hartford companies equipping in rapid succession, it seems that it cannot be long before a wave will pass over the country, the crest of which will land a storage battery in nearly every central station in its path.

LIFE IN THE OLD DOG YET.

IT is certain that the electrical exposition will demonstrate one thing, namely, the extreme liveliness of electrical industries after a prolonged period of dullness, deadness and disaster. Few branches of business suffered more cruelly than did the electrical in the grim panic of 1893, and what with low prices, failures and attempts at monopoly since then, it would seem that very little might have been left as a basis for hope and further endeavor. Yet no one can look around the exposition and fail to realize that the whole industry is full of briskness and brightness, fuller than ever of variety and new departures. It is surprising that doubt as to recovery should have been entertained, but when the road of recuperation is so long to travel, even the more sanguine grow weary.

We do not hesitate to say that the older arts are more solid and stable than ever, while new arts and wider developments are cropping up with a celerity and vigor equaling those of any other period electricity has ever seen.

Above all, it is interesting to look around and see how numerous are the young men who have faith in the future of electricity and crowd its ranks. We believe they will find plenty of room, with golden opportunities for work and reputation as well as for solid financial results. Moreover, the public, as it crowds into the exposition hall, will discover a miscellaneity of invention and application that it probably never dreamed of, and it will see that the end in electricity has not been reached.

NIAGARA IN NEW YORK.

CERTAINLY not the least interesting feature of a remarkably fine show will be the vivid presentation here of Niagara, in the manner that has already been noted in advance in these columns. Around the little model of the power plant of the Niagara Falls Power Company and of the city of Niagara Falls, have been massed a variety of methods, all of which must impress people with the resources of the electrical age we live in. The roar of the Falls is brought to the spot by the long distance wires of the American Tel. and Tel. Company. During most hours of the day the model is run by batteries stored at the Falls plant, and at night live current is delivered by two ordinary Western Union wires, whose run is not less than 465 miles. The tests of this, made successfully on Sunday night, show that some interesting facts will be reached by this demonstration, intended though it be merely as a pretty "tour de force." As a transmission to drive motors it most assuredly distances by far all previous records, and it is not the least striking detail that it is being done, up to the present time, with circuits having iron wire as well as copper in them protected only by telegraph insulation and running through offices and underground cables miles long.

Power Transmission.

TYLER'S SINGLE PHASE ALTERNATING MOTORS AND UNDERGROUND ELECTRIC RAILWAY SYSTEM.

A CONTINUOUS current motor may by alternating current start a single-phase alternating motor to synchronism, but it is quite a different matter to subsequently provide exciting-current for the alternating-motor field during synchronism. In order to accomplish this by the same auxiliary motor which is used for starting, as has heretofore been proposed, it is necessary to place two coils upon the fields of the starting-motor because the coils wound to suitable resistance for the starting alternating current will not be of proper length or cross-section for the succeeding continuous current

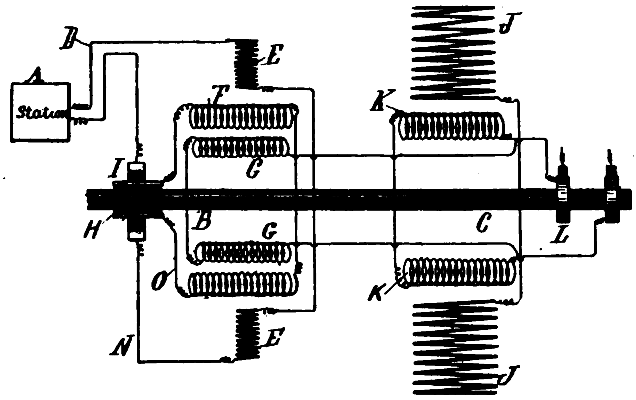

FIG. 1.—THE TYLER ALMERNATING MOTOR.

which must surround the same fields when the auxiliary motor is, as a dynamo, furnishing continuous exciting-current for the synchronous alternating motor. But this method is not practicable , as the two coils on the same field will be in inductive relation, and the transformer action occurring while the starting-coils are used is sufficient to generate a current in the idle coils of such high tension as to destroy them if open-circuited, while it is not allowable to short-circuit them, as they then impair the starting powers to such an extent that synchronism is too difficult to attain.

A novel feature of a motor constructed without this defect is that devised by Mr. Harry L. Tyler, of Corning, N. Y. This consists in employing for starting and for subsequent field excitation a motor which acts first as a starter and secondly as a revolving transformer. The accompanying Fig. 1 represents, diagrammatically, the relation of the circuits during the start-

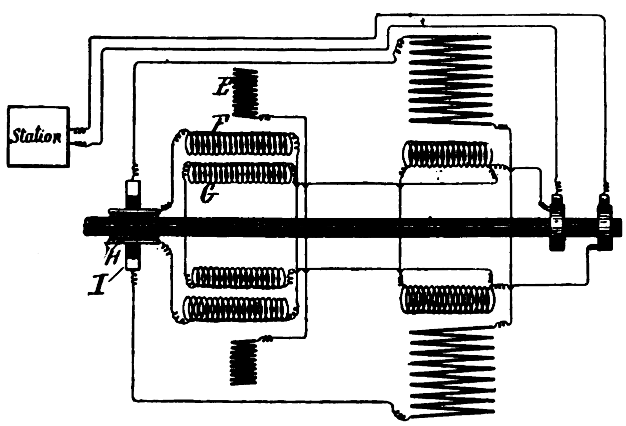

FIG. 2.—THE TYLER ALTERNATING MOTOR.

ing operation, and Fig. 2 represents a like view after synchronism is attained.

The revolving transformer and starting device are shown at B; C is the synchronous motor, and D the main line between motor and source. The revolving transformer and starting device is provided with the field coils E, armature coils F, and coils G. The coils F and G are supported and held in inductive proximity upon a core mounted on the armature shaft of the synchronous motor. On one end of the armature shaft is a commutator, H, provided with brushes. The synchronous motor C is arranged alongside of the revolving transformer on the same shaft, and is provided with the field coils J and armature coils K, the latter being in circuit with collector-rings L and M on the shaft.

The connections being established as shown in Fig. 1, the starting is effected in the usual way, the field coils E and armature coils F co-operating as in any motor until synchronism is reached. The coils G remain, of course, idle, until synchronism is reached, but when the revolving parts attain synchronism and the connections are changed, as shown in Fig. 2, the starting-motor becomes a revolving transformer, the coils G being the primaries and receiving alternating current from the line, while the coils F are secondaries and have induced in themselves alternating current of the same frequency as the line. The alternating current in coils F, as generated, is unavailable for the desired continuous excitation of the field of the synchronous motor, but as they are connected to the commutator H, and as the whole is revolving synchronously, it necessarily follows that the transformed current of coils F is delivered by brushes I as continuous, which is what is desired for the motor field excitation.

Mr. Tyler has also been devoting attention for some time to the development of an underground railway system. The system of distribution consisting of a single-phase underground circuit connected in multiple to primaries of transformers whose secondaries are in multiple with the track rails at intervals of 500 feet. Circuit-breaking apparatus is boldly discarded, the transformer primaries all being continuously connected to the underground mains while the secondaries remain constantly attached to the track.

Of course the entire track is thus constantly charged and it would seem that with the available potential the ground leakage as well as liability to personal shock would be prohibitive, but if we may believe reports, a mile of flooded uninsulated track with a voltage of 70 at a frequency of 300 per second shows a leakage of only 1,100 watts, while it is claimed to have been amply demonstrated that no perceptible shock is obtainable even with a hand held in contact with each rail. With a 1,000-volt Westinghouse alternator feeding the primary line at a frequency of 300 per second, a 7½ ton caboose has been propelled at a speed of fifteen miles per hour over the tracks of the Fall Brook Railway Company in the Corning yard, the single-phase motor on the caboose receiving power through the wheels at 70 volts.

A NEW SYSTEM OF SINGLE PHASE ALTERNATING CURRENT TRANSMISSION AND PERFECT ROTARY FIELD SINGLE PHASE POWER MOTOR.

BY J. G. J. SCOTT.

IT has been the endeavor of alternating current engineers for years to utilize single-phase currents for transmission of power to long distances and to apply such currents to long distance railway service. The transmission to distances has been accomplished with synchronous motors of different phases, some with fields excited separately by direct currents, and others being induction motors, or having the field and armature coils in series. All of these transmissions, however, have had faults that rendered them useless or inefficient except at full load, due to almost no regulation, in some cases between no load and full load, and in others the very large lagging current, and in all, the inability to start the loads they worked against. While the last fault was or is not fatal where motors are installed for power work where it is possible to use clutches, loose pulleys, and to start the machine with no load and then gradually put the load on after synchronism has been reached, the regulation factor has to be considered, and is in all single-phase systems very small when compared with direct current systems operating the same number of horse-power.

There are many places where it is necessary to vary the speed of a motor from its synchronous speed, and operate it for days at a time at these slower speeds. Again, it becomes necessary where a certain motor runs day after day at 6 or 8 horse-power, for it to develop 2 or 3 horse-power efficiently. With present types of single-phase motors it is impossible to change their speeds and have them do any efficient work if they are separately excited or induction motors.

Owing to the delay in getting into their new factory, the Scott & Janney Electric and Manufacturing Company, of Philadelphia, will be unable to get an exhibit of their new single-phase motors finished in time to show in operation in New York at the Exposition. They had hoped to be in a position to show their new single-phase rotary field street car motor, and the method of control. But it will be interesting for railway engineers to know that it is at last possible to operate single-phase motors for the propulsion of railway cars.

This new company have started into the field with a practical device, and have invented means of utilizing alternating

currents having a two-wire system. This is done by means of a device which they have termed an "induction director," by means of which, with ordinary single-phase currents, a great advantage is obtained over both direct current and polyphase systems, on account of the following facts: 1. The motors are non-synchronous. 2. They are differential in point of speed and torque to a very large degree. 3. They will be uncommonly light in weight for their output. 4. A perfect rotary field and magnetic poles of constant strength are obtained. 5. There are no dead points throughout a complete revolution of 360 deg. 6. The armature speed and the speed of poles traveling in field magnets are always identical; no matter what the mechanical speed of armature or the vibration of magnetism, the poles in both armatures and field magnets are synchronous. This is a most important feature. 7. The frequency is constant throughout the system, and is important. 8. The regulation is perfect, and on large loads at slow speeds there is great economy on account of the differential virtue possessed by these machines. 9. It is not as difficult to start a dead load with these motors as with direct current motors or with polyphase systems, and not near as much energy required from line. 10. The mechanical speed is independent of frequency. 11. There are no commutators and absolutely no sparking.

TELEPHONY AND TELEGRAPHY.

PROF. DOLBEAR'S AIR SPACE CABLE IN ENGLAND.

In 1882 Prof. A. G. Dolbear was in London, and there invented what he called an "air-space" cable for telephonic work. The conductor was to be inclosed in a paper tube, larger than the wire itself, so as to have air as an insulator and dielectric where rubber had been used before. He described three ways of making such a cable: one having the conductor lying on the bottom of the tube; the second having the conductor kept concentric with the tube by winding it with twine, and the third by winding the conductor with loose fibrous material. The paper tube inclosing the conductor was to be afterwards covered with waterproofing material and a shield when needful. Such a cable, he claimed, would have a much higher working rate on account of its low capacity. This patent was issued in England in March, 1882. Prof. Dolbear could find no one who would undertake to build such a cable although it was recognized to have superior qualities. He went to Mr. Latimer Clark, who was then making cables, also to the Silvertown Cable Company and to others, but none would touch it. It was not until laws were passed making it obligatory for telephone companies to bury their wires that such a cable became a necessity. Then such cables began to be made in great quantity both in England and America. For ten years nothing could be done with the patent, for there was no demand. Meanwhile the telephone interests of Dolbear had involved extensive and costly litigation, ending, as all know, in a decision adverse to him and leaving him hors de combat, unable to cope with infringers either at home or abroad. In 1892 Dolbear sold to the British Insulated Wire Company his English patent for £10, as there seemed no hope of getting more for it, and that company went extensively into the manufacture of the Dolbear cables, so that in three or four years there were laid some thousands of miles of it. Other companies also were manufacturing it without any acknowledgment.

The patent was to expire in March, 1896, and it was thought by the British Insulated Wire Company that as the inventor had not profited in proportion to the merit of the invention possibly the British government might grant an extension of the patent for a small term of years and an application for such extension was made. Some of the most eminent patent attorneys in England were employed, with Mr. Fletcher Moulton as chief. For electrical experts there were engaged Dr. John Hopkinson, Prof. S. P. Thompson, Mr. W. H. Preece, Mr. S. Z. Ferranti, Mr. G. H. Nisbett, with Prof. Dolbear. The hearing was before the Judicial Committee of the Privy Council, a body of Lords.

There was a little effort made by the opposition to show that the cables made by other companies were not the Dolbear cable, but Ferranti, Hopkinson and Nisbett testified that they were all the same thing and that there were no anticipations of the Dolbear cable. The applicant was not able to show that he had done anything with his cable patent during the ten years from 1882 to 1892 and the decision of their lordships was that this lack of activity was fatal to the application and it could not be granted. The witnesses, Mr. Preece and Prof. Thompson, who were present in order to testify why nothing could have been done were not allowed a hearing. The British Insulated Wire Company spent about $20,000 in this attempt, which shows how valuable they held the patent to be.

The American patent for the same invention was not taken out for three or four years after the English one, and by limitation of course, expired with the English patent. If the English patent had been extended as had been hoped, it might have had an important bearing on cable business in this country, for the British company proposed to establish a cable industry here, and with the American patent collect the royalties due for the millions of feet of the Dolbear cable in use in this country.

THE STROWGER TELEPHONE SYSTEM FOR NEW YORK STATE.

A CONTRACT has been closed, says the New York Journal, between the Automatic Telephone Company, of No. 35 Wall street, and a syndicate composed of some of the prominent capitalists of this city, Buffalo and Rochester, which will give to the persons interested the right to construct telephone lines and establish a long distance telephone service between all sections of New York State outside of that portion comprised in Greater New York. The system which will be used will be the one controlled by, and known as, the Automatic Telephone Company.

The syndicate has no corporate existence, and its representatives in making the contract act by private agreement with the men who are to furnish the money. It is believed that the money involved in this deal will be considerably more than $3,000,000. A charter will be applied for within a very short time, after all the necessary details have been decided upon.

Several thousand automatic telephones have been contracted for, and the agreement requires that not less than 1,500 shall be installed each year, during the life of the patents.

J. Wesley Allison, president of the Automatic Telephone Company, and W. Seward Webb, one of the persons interested in the syndicate, left New York last night for Buffalo, where many of the details connected with the sale of the rights in New York State will be further decided upon in connection with the Buffalo capitalists who are interested in the transaction. Among those who are in the syndicate are Tracy C. Becker, president of the State Bar Association, of Buffalo; William B. Rankine, vice-president of the Cataract Electric Company; Edward Mickel, a capitalist of Buffalo; John Jacob Astor, C. F. Cox, vice-president of the Canada Southern Railroad; William C. Whitney, Smith M. Weed, Silas B. Dutcher, of the Hamilton Trust Company, of Brooklyn; William L. Trenholm, president of the American Surety Company; John C. Maguire, Surveyor of the Port of New York; George S. Hart, president of the Second Avenue Railroad, and the banking firm of I. & S. Wormser.

It is expected that the first exchange to be constructed by this syndicate will be at Rochester, N. Y. Work will probably be begun there within the next two or three weeks. Buffalo will next be supplied with the automatic telephone, and then in turn the principal cities in the interior of the State through to Albany.

While this work is being done the consummation of a scheme for the construction of the same system in this city will be pushed. Already the agents for the telephone company have begun operations here, and the statement was made yesterday that over nine thousand contracts have been signed by subscribers. No franchise has been obtained by the company as yet, but those who are interested in the company feel confident that some means will be obtained within a very short time for either obtaining a new one or purchasing a franchise which is already in existence.

The Automatic Telephone Company was incorporated a year ago, with a capital of $6,000,000. It controls 160 patents and has thirty exchanges, the most important being Colorado Springs, Col.; Michigan City, Ind.; La Porte, Ind., and Trinidad, Col. The officers of the company are J. Wesley Allison, president; H. N. Whitney, of Kissam, Whitney & Co., treasurer, and A. B. Macklin, Secretary. The main feature of the system is that the switchboard operates automatically, and the familiar "Hello; What Number?" from the telephone girl, who frequently has not time even to say that much, will be done away with. As far as experiments go, the system has given satisfaction, and it is claimed that it can be operated on a much more economical basis than the Bell. The syndicate is negotiating for the control of the New England States, and it is not unlikely that within a few weeks additional contracts will be given them for this territory, which they will merge in one extensive system.

Exhibition Notes.

OPENING OF THE ELECTRICAL EXPOSITION.

BETWEEN 6,000 and 7,000 persons assembled in the main hall and galleries of the Industrial Palace on Monday night to witness the ceremonies attending the opening of the Electrical Exposition.

Shortly after 8 o'clock Governor Morton entered the space reserved for him in the gallery, accompanied by his private secretary, Colonel A. W. Cole, and by the reception committee, including Messrs. C. H. Wilmerding, president of the N. E. L. A., Mayor Wurster, of Brooklyn, Mr. F. W. Hawley, Mr. H. H. Vreeland and Mr. T. Commerford Martin.

After a brief introduction by Mr. Wilmerding, Mayor Wurster, in the absence of Mayor Strong, assumed the chairmanship of the meeting and in a few well chosen remarks introduced Commodore Perry Vedder, who delivered an address on "The Electric Era." The speaker dwelt at length on the great progress made in the electric arts in a comparatively brief period of time and concluded by stating his belief that "the greatest living traveler in electricity was as a child on the seashore of knowledge."

At the conclusion of Commodore Vedder's address, Governor Morton arose, and after expressing his thanks for the honor conferred upon him, declared the Exposition open. At the same instant he pressed a golden key—the same that had been used by President Cleveland in opening the World's Fair at Chicago—and thereby closed postal-telegraph circuits which fired cannon simultaneously in San Francisco, New Orleans, St. Paul, and Augusta, Me.

During the address of the Governor the Moore vacuum tubes, arranged as a frame around the speaker, were lighted as well as an emblem, "Let there be Light," and below it the initials "N. E. L. A."

Letters of congratulations were received from the mayors of Augusta and New Orleans, and from Mr. W. H. Preece, Engineer-in-Chief of the British postal-telegraphs.

After the ceremonies the thousands of visitors scattered throughout the building to inspect the exhibits, nearly all of which were in order. The crush was so great that at times locomotion was almost impossible. If the opening night is any indication for the future, the success of the Exposition is assured.

THE EXHIBIT OF THE NEW YORK EDISON COMPANY.

The exhibit of the Edison Electric Illuminating Company, of New York, is situated directly under the overhanging extension of the first gallery along the south side of the main hall, the space occupied being 84 ft. long by 10 ft. wide. As the visitor enters the main hall from the stairway, he will see a pictured representation of the great operating room of the Duane street central station, in front of which will be shown actual sections of the electrical controlling apparatus constructed on the Van Vleck edgewise system, similar to that in use at the Duane and Twelfth street stations. The apparatus in the center consists of a dynamo controlling section complete with edgewise ampere meters for regulating two large-size multipolar dynamos; while at the side, near the column, is shown the feeder controlling apparatus, having a capacity sufficient to control both poles of four feeders each of 1,000 amperes capacity. Current for this exhibit is supplied to this feeder switchboard from the Edison street mains, and from a storage battery, to be seen behind the exhibit, similar to the batteries in use in the Edison stations. From this switchboard, the current passes through an Edison feeder-tube, such as is used in the city street, after which it passes into a feederbox, thence to a distributing box, and thence through a street main to a service-end box, such as is placed on a consumer's premises. Alongside the feeder box is one of the new controllable junction boxes, as developed by the company, by which a tie-feeder between two stations can be divided from the station into individual service feeders. From the service-end box, current is carried through an Edison chemical meter, such as is usually placed in a customer's premises, and also through a Thomson wattmeter; after which it is distributed for its varied applications in lighting (incandescent and arc), power, cooking, heating, etc. Two arc light posts, constructed on the Edison-Bowker system of street lighting, and similar to those in use on Fifth avenue, are placed at the front of the exhibit.

In the center of the main exhibit is seen an illuminated representation of the upper field frame of the huge 800 kilowatt dynamos now in use at the Duane street station, the largest lighting generators in the world, capable of supplying current for more than 12,000 16 c. p. lamps.

In the next space beyond is shown an interesting collection of various electro surgical and dental apparatus, together with electric fans and an electrically driven sewing machine. Electric cooking is also shown in practical operation, with electric ironing, and electric heating; an "electrotherm" for bedwarming, poulticing, etc., will be of interest, as well as many other applications. The power exhibit at the extreme end includes a modern printing press run by electricity without belt or shafting. Elevators run by electric current are shown elsewhere in the building.

Directly behind the large dynamo field frame is an interesting collection of photographs of the principal stations, supplying more than 6,000 customers, with over 300,000 incandescent and 3,700 arc lamps, and about 15,000 horse-power for power and miscellaneous purposes, forming the largest installation of any electric supply company in the world. In addition to this exhibit in the main hall, there is an electrical dark room, in which is a joint exhibit of electric lamps manufactured by the General Electric Company, and supplied by the Edison Company. This room illustrates various methods of lighting, including the latest plans for using reflected light from concealed lamps. Electric signs and advertising specialties are also here exhibited.

THE MEDBERY INSULATION AT THE EXPOSITION.

The Fiberite Company, of Mechanicsville, N. Y., display a full and complete line of their insulating materials for overhead trolley equipment and Medbery insulation, which is so generally used on the leading electric railways of the country.

They also display a very handsome line of switches of every kind as well as a very substantial switchboard for lighting and power purposes.

This display is in charge of Wendell & MacDuffie and Mr. H. J. Medbery.

THE WARREN ALTERNATOR AT THE EXPOSITION.

The Warren Electric Company, of Chicago and New York, display on the first floor, one 60 kilowatt Warren alternator, alternations 9,000 per minute, connected for 110 volts, of their latest induction type, stationary armature and stationary field coil machine; also one 45 kilowatt Warren alternator of the same general style.

This machine is having a very large sale, having only recently been put on the market. These machines have been in use about a year and not a single dollar has been spent upon one of them for repairs.

These machines are in charge of Wendell & MacDuffie and Mr. H. P. Hill.

APPARATUS FOR THE PRACTICAL LABORATORY.

In addition to the historical apparatus to be loaned the Exposition by Dr. R. Ogden Doremus, the following pieces of the laboratory type have also been placed at the disposal of the management: From Bellevue Hospital, Medical College, egg shaped globe for exhibition of the electric arc in vacuo; same for exhibition of electric arc in water; Hoffman apparatus for decomposition of water. From the College of the City of New York, models showing beautifully the operation of the telephone; Erdmann galvanometer; ampere table; apparatus for development of heat by current and quantitative estimation of same; revolving Geissler tubes; Hertz mirrors; photophone; exhibition of diamagnetism. This will all be in more or less continuous operation.

LOAN OF HISTORICAL TELEPHONE APPARATUS.

Mr. E. J. Hall, Jr., vice-president and general manager of the American (Long Distance) Telephone and Telegraph Company, has very kindly loaned to the Exposition the original long distance telephone set with which some years ago Prof. Alexander Graham Bell opened the line between New York and Chicago. It has since that time been jealously guarded, and has had a silver plate put upon it with the inscription as to date, etc. Mr. Hall accompanies this with a large picture, illustrative of the event, and with other material bearing upon the occasion.

Mr. C. R. Truex has been entrusted with the care and arrangement of this interesting exhibit, which goes in the collection of the Historical and Loan Exhibit Committee.

MISCELLANEOUS.

THE RELATION BETWEEN THE ELECTRICAL TRADE AND THE HARDWARE BUISNESS.[1]

BY JULIUS M. AFF.

THE question naturally arises, is it advantageous to a retail hardware dealer to sell electrical supplies? Above everything else, does it pay to keep them, to advertise, and to install them if necessary? In fact, is the hardware store a proper place for the sale of electrical goods?

In my opinion a hundred dollars judiciously invested in first-class electrical goods will pay as well as anything that you may have in your store, providing your salesmen know their business, know how to satisfactorily explain to your customers the working of all appliances, and can make suggestions as to possible ways and means to accomplish a desired result, and as to remedies for existing faults. Such a stock of goods need not extend beyond what is known as household electric supplies, covering such appliances as are now to be found in most all well appointed modern houses.

Customers' Inclinations.—What is more natural for any one who may want to purchase an electric bell than to go to the nearest hardware store for it? Are electric bells any less in our line of goods than the old-fashioned jingle bells, or push buttons less so than bell pulls? Does the fact that copper wire is covered with some insulating material exclude it from the hardware store? If there is any place on earth suitable for the sale of electrical supplies it is a hardware store.

Installing Electrical Appliances.—As to doing electrical work, putting in electric bells, etc., it would be advisable for the hardware merchant to keep a competent electrician at his store at all times, one who can turn a hand to most any kind of work when not very busy in his own line; and when Dr. Smith's or Dentist Jones' front door bell is out of order they could be accommodated at once, which fact they would very much appreciate. Insist upon having your workman do all work to the best of his ability, and if by reducing the profit on the job by a few cents you can give your customer better work, it will pay you very much better to do it than to send again in a short time, and spend hours in locating faults in material or workmanship. Many installations are unsatisfactory through insufficiency of battery power since the efficiency of batteries decreases as they become older. One or two cells over and above what is absolutely necessary represent a small item of expense, tend to make everything work more positively, and the whole battery will not require recharging so often, as it does in cases where the battery is just sufficient to do the work while the whole installation is new.

Again, I say let your material be of the very best that can be procured, since the best is none too good for a first-class job, and no other kind of work should be done by any one who expects to make his work pay.

Unsatisfactory Work.—Any one desirous of having a good and lasting job of electric work done would prefer going to a reliable hardware merchant who has a reputation to uphold, one who would rather lose money on the job than give his customers just cause for complaint, than to employ some person unknown to him or to any one else who may be here to-day and somewhere else to-morrow, either measuring ribbon or selling stove polish, but who knows all about electrical work when he sees a chance to make a few dollars. To an individual of this type the question of cost, of time and of material is only a secondary consideration. He does the job at cut-rate prices, with the result that the trusting victim comes to your store about one month after that asking the price of putting in an old-fashioned jingle bell, and at the same time condemning electric bells and everything connected with them. Then is your chance to rectify the trouble and gain the custom of this man and of many others through his influence.

Adaptability of Electrical Appliances.—The range of usefulness and the conveniences which a few cells of battery in your house or place of business can afford you is almost beyond enumeration. The slightest pressure of a finger will ring any number of electric bells, irrespective of size or distance, from one single push button. One single bell may be rung from any number of pushes or other contact devices. Simply pulling a chain will light or put out the gas. Automatic gas lighting burners can be lighted or put out at any distance by simply pushing a button, opening or closing a door or window, entering or leaving a room, and in various other ways. An ordinary electric alarm clock in connection with other electric appliances can, while you are absent or asleep, light your gas or electric light; light your gas stove, and have the water boiling by the time you are ready to use it; feed your horse or cattle; awake you or your servants, and afterward keep on ringing until you get up and turn off the current. The electric burglar alarm informs us that some unwelcome visitor is trying to force an entrance, and at the same time designates the place where he is at work.

In burglar alarm work we recognize three distinct systems: The first is the open circuit system, which is the one mostly used for interior house work, where all wires can be concealed, since the cutting of one single wire may disable the whole installation. The second is the closed circuit system, which is more adapted to outside work, such as protecting a barn or warehouse, or anything where connecting wires to the owner's house are visible and accessible to most any one. In this case the cutting of wires would result in ringing the alarm, whereas simply short circuiting would disable the system. The third is a combination of both the open and closed circuit systems, and neither cutting of the wires nor short circuiting them will affect its working.

Additional Applications.—The electric thermostat or heat controller regulates the temperature automatically in our homes, greenhouses, incubators, etc., or at the very least notifies us when it is getting too warm or too cold for any particular purpose. The electric automatic fire alarm is just such a thermostat. The telephone would be almost useless without its battery. Electric door openers will open our doors at a distance and save us many a tiresome walk up or down stairs. Electric matting, laid under carpet, will inform us of the presence of some one at that place. High and low water alarms and regulators in boilers or tanks can automatically control the flow of water. In the sick room electricity adds materially to the comforts and even health of the patient by running fans to cool the fever-parched body, indicating the proper time for taking medicines, and in the hands of the skillful surgeon electricity is of untold value in the saving of human lives. Mining and blasting accidents are less frequent since we employ electricity to ignite the most powerful explosives.

Permanency.—The mechanically inclined boy who formerly aimed to be the happy posssor of a tool chest, fret saw, lathe or steam engine, now includes in his outfit electric batteries, bells, toy motors and magnets of all shapes, and delights in making movable toys of all descriptions, since he has found in electricity the only convenient motive power for them.

You as a possible buyer might say: "Will a system do all this work after it is put in and paid for; and, if so, how long will it last?" I will here say that there is no reason why the installation should not last as long as the very building where it is put in, if the job is properly done and correspondingly paid for. When architects become more explicit in their specifications, and invite only responsible bidders, then we shall have better work and a general stimulation of the electrical trade.

[1] A paper read before the Philadelphia Hardware Association. Mr. Aff is with the hardware firm of J. Jacob Shannon & Co., of Philadelphia.

MOTOR REGULATION BY FIELD VARIATION.

BY PROF. W. A. ANTHONY.

IN The Electrical Engineer of April 15 I find a description of Burke's "Method of Regulating Motors." The writer of the article omits to mention one method of varying the speed, namely, varying the field of the motor, and, furthermore, it seems to me his way of stating the case is likely to lead to a misapprehension as to the size of the machines that will be required.

As he states the problem, it is "to deliver 10 horse-power at any speed between 100 and 500 revolutions * * *" But the cases are extremely rare where such a condition will exist. Usually the condition to be satisfied is more nearly that of constant torque than of constant power. In running a printing press, or an elevator, in every case where the work to be done can be likened to friction overcome or a weight lifted more or less rapidly, the power increases at least as rapidly as the speed.

Assume that the motor is used to run an elevator and that at a speed of 100 the power required is 10 horse-power. At 200 revolutions the power required would be 20 horse-power, and at 500 revolutions 50 horse-power. But at a speed of 200 revolutions one motor must do all the work, and it must therefore be a 20 horse-power motor at that speed. The speed of 500 revolutions is obtained by making one of the motors act as a generator, and, assuming the voltage of the line to be 100, the generator must add 150 volts. Now the one machine must furnish 50 horse-power to run the elevator and 75 horse-power to run the generator coupled to it, or 125 horse-power in all, and this assuming the efficiency of the combination to be 100 per cent.

But to assume the conditions of the article, that 10 horse-power is to be delivered at all speeds. At 500 revolutions the motor must deliver 10 horse-power to the work and 15 horse-power to drive the generator, which must add to the voltage of the circuit the 150 volts necessary to obtain the speed of 500 revolutions. The motor must, therefore, deliver 25 horse-power when running at 500 revolutions, but if it can deliver 25 horse-power with full strength of field it can deliver the 10 horse-power of useful work with the field reduced to two-fifths its normal strength, and with that strength of field it would run at 500 revolutions on a 100 volt circuit. By making one machine capable of delivering 10 horse-power at 100 revolutions—a machine that would be less costly than two machines of 5 horse-power each—the regulation of speed could be obtained by varying the strength of its own field, with the same facility as by the method described by Mr. Burke.

In short, the method described by Mr. Burke will require, to deliver 10 horse-power at all speeds, from 100 to 500 revolutions, two machines of such size that they would, if properly wound, give 25 horse-power each, or 50 horse-power total at 500 revolutions, and at the normal voltage of the line.

If the power is to increase with the speed, as in running a printing press, or a street car, or an elevator, with 10 horse-power as the minimum, then the two motors would need to be of such size that if properly wound they would deliver at least 125 horse-power each at 500 revolutions, or a total of 250 horse-power.

In the system which supplies a varying voltage to the armature of the motor by means of a rotary transformer this last result may be accomplished by means of three machines of 50 horse-power each, or 150 horse-power in all.

THE BREVOORT METHOD OF WATERPROOFING FABRICS.

A PATENT has just been issued to the executors of the late Henry L. Brevoort in which that inventor describes a novel process for waterproofing textile fabrics.

In carrying out the process, the fabric to be treated is wetted with water and placed between sheets or rollers. One of these sheets or rollers, which is preferably of tin or aluminum, is connected to the positive pole of an electric generator and the other sheet or roller to the negative pole. By employing such a dissolving positive electrode and passing current through the wet fabric the fibers are made water repellent.

The inventor states that the waterproofing is due to the formation on the positive conductor of a metallic oxide of some kind produced by the liberation of nascent oxygen on the positive conductor due to the electrolytic action of the current on the water with which the goods are saturated, and which oxide enters into the fibers of the goods aided by the current, and probably is combined partly chemically and partly mechanically with the fibers, making the same waterproof by the presence of the oxide in or on the fiber.

The strength of the current applied depends upon the character of the goods submitted to treatment, but care must be taken not to carry the process too far. The nascent hydrogen on the negative side will, if the time of treatment is too long, accumulate and then begin to act as a reducing agent, and in case the period of treatment is prolonged beyond the proper time then the nascent hydrogen will reduce the oxide of the metal in the goods to the metallic state and the combination or union of the oxide with the fibers will be destroyed by the reduction of the oxide to a metallic state.

This process is said to have the great merit of making the individual fibers and threads water-repellent, while the pores of the goods are in no way stopped up or closed. Consequently, if used on clothing, it would not prevent evaporation taking place through the interstices between the threads.

CINCINNATI ELECTRICAL NOTES.

MR. JOHN CABOT, city electrician of Cincinnati, has instituted a novel experiment in the electrical equipment of a house.

The "sensitive room" properly speaking, is a room fitted up with electrical apparatus, and so contrived as to transmit any conversation occurring between persons confined therein. Mr. Cabot fitted up such a room in the Central Police Station, with invisible electrical appliances, so as to make every word uttered in the cell audible to the listeners stationed in the connected room on the top floor

The cell is slightly larger than that of the average police station cell, with a partition running through the center, in which the prisoners expected to converse with each other are placed. There is nothing unusual about the rooms, all the appliances being concealed from view, excepting one or two small copper tubes, which would attract no attention.

On the front of the cell, midway between the two iron doors, is attached a simple wire screen, ordinarily used to cover and protect fumigating boxes, being modeled after the system now in vogue throughout the cell rooms in the Cincinnati Police Station. Just beneath this is a novel arrangement, through which the sounds are transmitted to the "watch room" above. To this contrivance, wires and tubes are attached, which are arranged in a deceptive manner, so as to make it appear that the wires and tubes join those leading to the hydrant. This is done in order that the suspicion of the inmates may not be aroused.

Any conversation occurring in this room passes through the wire screen and into the transmitter, and thence into the ear of the authorized eavesdropper in the receiving room above.

This device was suggested by the necessity for some such contrivance on account of the inability to procure incriminating evidence against George H. Jackson and Alonzo Walling, the medical students, who are supposed to have murdered Pearl Bryan, who was found dead near Cincinnati in February.

It was impossible to obtain incriminating evidence against either prisoner, but when placed in these cells, they seized the opportunity to converse with each other, having been separated previously; the device above referred to then came into play, and by that means a lengthy conversation was transmitted and overheard, which will doubtless convict them both.

The Cincinnati Street Railway Company has applied to the Legislature, through what is known as the Rogers bill, for a fifty years' extension of its franchise, which would expire under the present franchise in sixteen years. The company, of which Mr. John Kilgour is president, and James A. Collins secretary and treasurer, is meeting strenuous opposition from the press and people, who seem inclined to give the measure the "marble heart," claiming that the street railway already pays a high interest on an inflated capital, and should be allowed no further advantages.

If the bill passes the company will remove the somewhat antiquated cable car, and run all lines by electricity.

THE PHILOSOPHER'S STONE AT LAST.

A special dispatch from Cedar Rapids, Ia., of April 20 says: George Johnson, a young farmer residing in Jefferson County, a graduate of Columbia College, who has been experimenting with the X-rays, thinks he has made a discovery that will startle the world. By means of what he called the X-rays he is enabled to change in three hours' time a cheap piece of metal worth about 13 cents to $153 worth of gold. The metal so transformed has been tested and is pronounced pure gold.

A BOOK ON ROENTGEN RAYS.

A book that ought to be very successful is announced on "Röntgen Rays," and all the experiments concerning them. The author is Mr. E. P. Thompson, and his collaborators are Prof. W. A. Anthony, L. M. Pinolet and Ludwig Gutmann. The work will be very comprehensive. It is to be brought out by the firm of D. Van Nostrand Company. It cannot appear too soon.

SOCIETY AND CLUB NOTES.

TRIP TO THE CROCKER-WHEELER FACTORY.

On Thursday evening, by special invitation, the National Electric Light Association and its friends will make a trip by special train to the factory of the Crocker-Wheeler Electric Company, at Ampere, N. J. Special tickets have been issued for this very interesting trip. The special train leaves Christopher and Barclay street ferries at 8.10, and provision has also been made on other trains. The big new factory is an ideal exemplification of what is being done in the construction of motors and dynamos and the interior transmission of power. Dr. S. S. Wheeler, president; Prof. Crocker, Mr. Lufkin, Mr. Dunn and others will receive the guests.

THE HENRY ELECTRICAL CLUB.

Prof. F. B. Crocker will deliver a lecture before the Henry Electrical Club on "Troubles in Dynamos and Motors," on May 8.

THE A. I. E. E. AT THE KELVIN CELEBRATION.

The American Institute of Electrical Engineers has been invited to send a representative to take part in celebrating the jubilee of the professorship of the Right Honorable Lord Kelvin, which will take place in Glasgow, June 15 and 16.

President Duncan has appointed Past-President Martin to represent the Institute on this interesting occasion. Mr. Martin will sail on June 6, and while absent will lecture before the Royal Institution on the subject of the Niagara Power Plant.

ELECTRIC TRANSPORTATION.

THE K. A. K. SURFACE AND SUB-SURFACE ELECTRIC RAILWAY SYSTEM.

WHILE the trolley electric railway has had a deserved success, indications point strongly to large application in the future of the conduit system. Enough has been demonstrated to prove the practicability of placing railway wires below the surface of the ground, and it is probably only a question of time when, in our larger cities at least, the trolley will give place to the conduit. At the same time inventors are looking forward to the time when steam roads will be forced to employ electricity, and a step in that direction has been made by Messrs. Knotz, Allen & Kelly, of Springfield, Ohio, in their so-called K. A. K. electric system. The conduit employed in this system for steam roads is shown in cross-section in Fig. 1. It is composed principally of steel casings, with substantial cast iron yokes or frames, about six feet apart, making a very substantial conduit, the yokes forming the supports for the pipes and lids also shown.

Referring to Figs. 1 and 2, A A is the supporting yoke, D^3 ordinary gas pipe 1½ to 3 inches diameter, supported by insulators D^1. In this gas pipe are placed the feeders E, which extend the entire length of the track, and connected to these at suitable distances of 500 to 700 feet, by means of switches and fuses inclosed in water-tight boxes, are auxiliary feeders E^1, each of sufficient size to carry the current and for feeding independent sections of the rails, C, of the same length, or the distance between the switch boxes. This admits the cutting out of any section of rails, C, either automatically for cause or when necessary for inspection, without interfering with the operation of the line. Contact between supplementary feeders E^1 and rails, C, is made every twenty-four feet by the bolts D^5 which passes through the insulators D^4, which enters the pipe through the T-couplings D^2.

The insulators for supporting the pipe and the rails on the pipe are large, and especially designed for this purpose. The contact rail C is of steel, presenting a wide surface for contact with the trolley shoe. It will be seen that for any of the current to escape it must pass through a quadruple insulation; that is, the insulation inclosing the feeders, and the insulators supporting the gas pipe, which inclose the feeders on the positive side, also through a like insulation on the negative side.

Inasmuch as the insulated feeders are inclosed in the airtight tubes or gas pipes, and free from all atmospheric conditions, and the tubes also exceedingly well insulated, it reduces the possibility of the current breaking through this insulation, to a minimum.

In the form of conduit designed for street railway purposes the insulators are supported on a frame upon which the lead-covered feeders are supported. There is no supplementary wire, but a direct connection from the switch to the contact rails, which are banded together in lengths corresponding with the distances between the switches.

A line equipped on the K. A. K. system is now in operation in the streets of Springfield, Ohio.

STANDARD UNDERGROUND.—Mr. P. H. W. Smith has been appointed assistant general manager of the company, and Mr. F. S. Viele has been made manager of the conduit and general construction departments at Pittsburg.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—XI.

BY

Wm. Baxter, Jr.

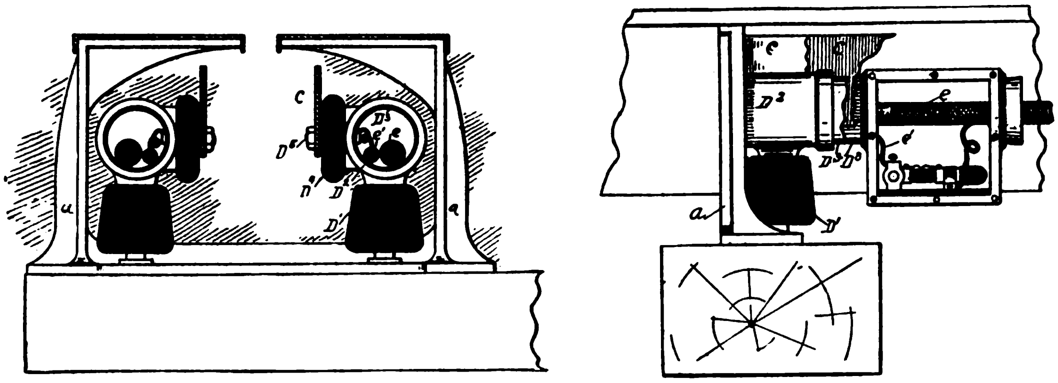
WE have seen from what has preceded that we can cut off seventy per cent. of the cost of repairs to locomotives because these repairs are made on parts of the machine that have no counterpart in the electric system. There then remains thirty per cent., which covers the cost of repairs to the machinery proper of the locomotive, that is, the cylinders, pistons, crossheads, connecting rods, valve rods, link motions, etc. Now, it is evident at a glance that the cost of keeping up these parts must be very much greater than the cost of repairs to motors. The wearing parts in a motor mounted on the axle would be the two journals and the commutator.

When the great difference in the number of wearing parts is taken into consideration it must be conceded at once that at the most the cost of repairing the motors could not be more than one-half of what would be required to keep up the machinery proper of a steam locomotive. This being the case, the repairs of motors would amount to only fifteen per cent. of the repairs of locomotives.

It may be said by those who are familiar with the history of electric street railways that this assumption as to the small cost of maintenance of motors is not justified, in view of the fact that the actual operations of such roads do not show such results; but it must be remembered that the difference between the cost of repairs on modern equipments and those made several years ago is very great. The principal causes of deterioration in early machines were that they were made of too small capacity to do the work required of them, and also that the insulation was not as perfect as it might be. The gears were not encased and consequently soon wore out under the action of grit and mud. The journals were not dustproof, and therefore the brasses had to be frequently renewed. Lightning did a great deal of damage, owing to the imperfect protection of arresters and the defective insulation of motors. Motors made to replace locomotives would be free from the defects of the earlier machines used on trolley roads; in fact, they would be far more substantial than the motors of small size now being turned out by the best makers. The designers of such machines would not be hampered by any restrictions as to size or weight, therefore every part could be made of ample size to allow for the most substantial insulation, liberal cross section of wire, and large wearing surfaces. Machines so constructed would be almost everlasting.

The assumption that the cost of repairs to motors would be fifteen per cent. of the amount expended on locomotives is really unfair to the electric motor. This relation would hold good for an equal number of locomotives and motors, but as a motor car could easily make fifty per cent. more mileage, the number of motors required to do the work would only be two-thirds, so that, as a matter of fact, the cost of maintaining the electric equipment of a road would be nearer ten than fifteen per cent. of the cost with locomotives.

The next item to be considered is that of repairs to shop machinery and tools. We will pass over this lightly because the amount is small and it would make but little difference in our



FIGS. 1 AND 2.—THE K. A. K. ELECTRIC RAILWAY CONDUIT SYSTEM.

calculations whether we include it or not. But it is evident that a reduction can be made, because as the repairs to roadway, bridges and motive power are greatly reduced, fewer men would be required in the shops for this part of the repair work, therefore the cost of keeping up the machinery and tools would be less. As this expenditure in maintenance of machinery and tools no doubt covers those used for car repairs as well as for the purposes here enumerated, it is probable that not over one-half of the amount would be affected by the reduction. We might justly assume that this half could be reduced twenty-five per cent., which would equal about twelve per cent. of the whole bill, but in order to be well within safe limits, we will call the saving only five per cent.

We now come to a charge that is of very decided importance, that of wages of engineers, firemen and round-house men. We see from Table 13 that this item amounts to $3,222,974.47. From Table 14 we find that the total of engineers and firemen amounts to $3,169,465.05, from which we can conclude that the wages of round-housemen amount to $53,509.42. As has already been shown, the wages of firemen can be saved by using motor cars, because in passenger service the baggage car could be used for this purpose, and on freight trains the caboose; and in either case the other men in the car could be required to remain in the motorman's compartment while on the road, so as to be ready to take the lever in case of emergency. The round-housemen could be reduced fully one-half, if under this head are included the men who clean up the engines, as with motors there would be practically no cleaning to be done. Making this assumption, we would find that we could reduce this item by $1,147,103.51, an amount which is about 36 per cent. of the entire charge for this service and constitutes nearly 2.8 per cent. of the total expenses of operating the road. We will next take up the cost of fuel for locomotives. To determine accurately the saving we would have to know the amount of coal consumed and the relative proportion allotted to passenger and freight service and also to switching engines. The report only gives the total cost, and therefore the weight must be estimated as well as the cost per ton. In previous paragraphs an estimate was made of the total power required to draw freight trains on the Pennsylvania road, and this was carried out far enough to show the number of tons used per year. If the calculation is correct this number would be 1,183,220 tons.

In making this calculation we were assisted by the fact that the report gives the average amount of freight per train and the average speed. Having this data, it is possible to calculate with a fair degree of accuracy the power required to draw the average train, and thus to obtain the average coal consumption. As the number of freight train miles is also given, the simple multiplication of the coal consumed per mile by the train miles gives the total consumption for the year. If we could obtain the same data for passenger trains on the Pennsylvania road as for freight, a similar calculation could be made, but unfortunately there are no data in the report from which any accurate estimate of the average number of cars in a passenger train can be made; therefore no calculation as to average power and coal consumption can be given, as it would have to be based wholly on assumptions; but it is generally conceded that a coal consumption of 65 pounds per train mile for passenger work is about as good a result as can be obtained on an average. Estimating the coal consumption of passenger trains on this basis, we would have:

$$\frac{14,908,880 \text{ (train miles)} \times 65 \text{ (lbs.)}}{2,000} = 484,538 \text{ tons (approx.)}$$

Assuming the coal consumed by switching engines to be at the rate of 100 pounds per mile, we would have:

$$\frac{10,298,317 \text{ (miles)} \times 100 \text{ (lbs.)}}{2,000} = 514,966 \text{ tons.}$$

This number of pounds of coal per mile for switching engines must certainly be under, rather than over, the actual amount, as will be evident when we consider that such engines cannot average as many miles per hour as freight trains, owing to the fact that they only make short runs, and then wait a considerable length of time before making another run, so that although they may be in service all day long with a full head of steam on, the actual number of miles run would not be very great.

From the foregoing estimates we would get the total number of tons of coal consumed per year as follows:

For passenger engines	484,538 tons
For switching engines	514,966 tons
For freight engines	1,183,220 tons
Total	2,182,724 tons

The cost of this amount of coal as per the report of the road is $3,724,481.14, therefore the cost per ton is nearly $1.71.

If these calculations are correct, then the average cost of coal per ton as given above is not far from the actual figures, and by taking the number of tons used in each branch of the service and multiplying by this price, we can get at least an approximate apportionment of the fuel bill to the different classes of work. Doing this we get the following results:

Passenger service	484,538 tons @ $1.71 =	$826,800 approx.
Freight service	1,183,220 tons @ $1.71 =	2,018,900 approx.
Switching service	514,966 tons @ $1.71 =	878,781 approx.

In calculations already made we have shown that the cost of coal per unit of work done by electricity would be about 31 per cent. for freight and 37 per cent. for passenger work of the cost of the same service by steam. Reducing the above amounts by these percentages, we would have the following figures as representing the cost of coal consumed for passenger and freight service by electric motor:

Passenger service	$826,800 × .37 =	$305,916
Freight service	$2,018,900 × .31 =	625,859
		$931,775

As already pointed out the coal consumption of switching engines per horse-power hour must be very high on account of the intermittent character of the work, but the efficiency of electric motors in this service would be just as high as in any other, as no current would be used while not in motion; while in a locomotive the coal is burning up all the time, whether in motion or not. Now, if a saving of 69 per cent. can be made in doing the freight work, it is undoubtedly reasonable to assume that the work of switching engines could be performed at a saving of from 80 to 85 per cent. Taking the lowest figure we would have:

Cost of coal for switching engines, 514,966 × .20 = $102,993.

The total cost of coal for all services would be:

For freight and passenger	$931,775
For switching engines	102,993
Total	$1,034,768

Total saving in fuel item, $2,689,713.14.

Percentage of fuel bill saved (about) 72 per cent.

Percentage of the total operating expenses, that the saving in fuel would amount to, (about) 6.5 per cent.

THE "STANDARD" AIRBRAKE APPARATUS.

THE tendency of electric railroading is towards constantly higher speed, and all the electric equipment of street railway cars has gradually been brought to a condition with this end kept steadily in mind. But while high speed is desireable in many ways, it introduces danger from accidents to persons and damage to property which statistics have shown to have multiplied enormously since the adoption of electricity as a substitute for the horse. The reason for this will be readily seen by a glance at the following table, showing the distance in feet traveled by a car at various rates of speeds. A fraction of a second lost in the application of the brakes may thus mean life or death:

Miles per hour.	Feet per second.
6	8.8
8	11.7
10	14.6
15	22.0
20	29.3

When it is considered that in addition to the higher speed at which they are run, electric cars frequently weigh three to four times as much as the old horse car, and that the latter had the advantage of ten feet, occupied by the horses, it is not surprising that the hand brake has been found entirely inadequate to cope with the new order of affairs, and that some form of mechanical brake must inevitably be used to secure that reasonable safety which the public has a right to demand.

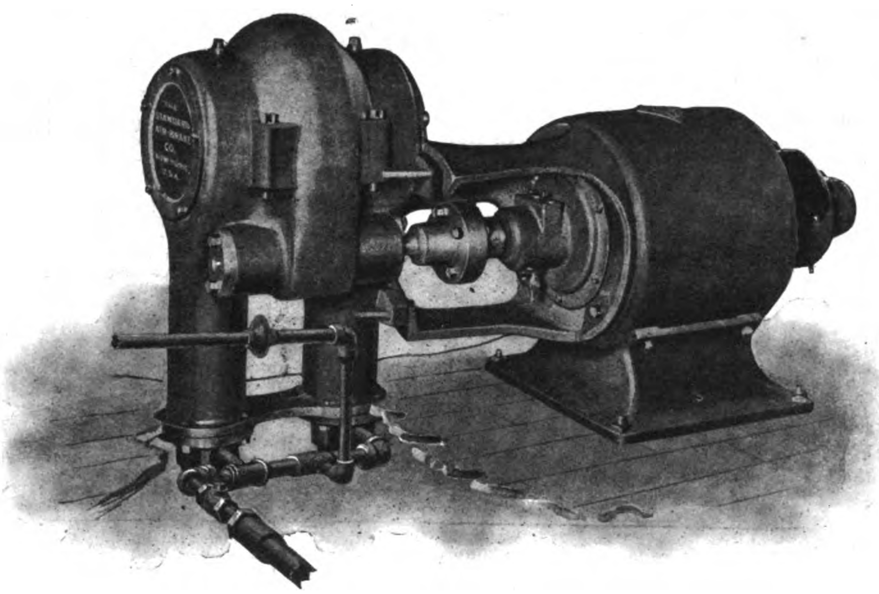
Theoretically, of course, there is a minimum limit within which cars of a given weight and velocity can be brought to a standstill, even with the most efficient brakes that can be devised. This limit is determined by the adhesion between the wheels and the rails, which at its maximum is about one-quarter of the weight resting on the wheels.

A still more important factor in braking is the manner in which the brakes are applied, due to the fact that with a given brake pressure, the braking effect is less at high speeds than at lower speeds; consequently a much higher pressure may then be applied without danger of skidding.

The airbrake is acknowledged to be the best adapted of all forms of brakes, in the application of the above facts, and among the first, if not the very first, to undertake the solution of the problem of street car braking was the Standard Air Brake Company, and in their catalogue, about to be issued, they describe in an admirable manner the latest improvements

in their system. These embrace nearly every detail of the braking apparatus, the latest arrangement of which for city street railway traffic is well shown in the insert in our advertising pages.

One of the most important details of the braking apparatus is the air compressor. The great desideratum in its working is that the power expended should cease the moment the desired pressure is attained in the reservoir. This is accomplished in the Standard brake, as follows: As long as the air has not reached the set pressure to be carried, the compressor forces air through the discharge-valve direct to the reservoirs, and continues to do so until the desired pressure is reached. The pressure will then open the regulator-valve and admit air into the governing chest under the diaphragm, forcing upwards the governing-piston and lifting the suction-valve from its seat. This opens the air-cylinder and allows the compressor-piston to move in free air and do no work, until by application of air to the brake-cylinder, the pressure is reduced. This, acting upon the regulator, releases the air confined under the diaphragm, and allows the governing-piston to fall, reseats the valve, and the compressor resumes furnishing the pressure. In making a stop, only one or two pounds registered pressure is required, and this the compressor furnishes again before the car has traveled thirty feet, although the reservoirs hold in reserve ten times the amount of air required to stop the car, even without additional supply. The air-pressure is thus practically inexhaustible.



"Standard" Electric Air Compressor for Interurban Roads.

For city traffic the Standard Company has designed a geared axle type of compressor and the gearless electric compressor shown on the insert above referred to, which runs almost absolutely without noise. The accompanying engraving shows the motor-compressor design for interurban roads. As will be seen, all its parts are enclosed in dust-tight covers. In both the city and interurban types the motors driving the compressor are provided with automatic regulating apparatus, which throws the motor into action as soon as the pressure is reduced below its proper limit, and stops it as soon as the proper pressure is obtained. Thus the motor does no work except at times actually required.

Among other improvements made in the Standard system is that effected in the controlling apparatus. This now consists of a special interlocking handle, which, when withdrawn by the motorman, leaves the brake-valve closed, so that the apparatus cannot be tampered with by mischievous passengers.

We might enumerate many other details of like character, but the above will suffice to indicate the perfection to which electric car brakes have been brought in a comparatively short time. The Standard Air Brake Company's catalogue is a masterpiece in its way, not the least of its merits being its comprehensive index.

WHAT A BROKEN POLE DID.

A remarkable accident occurred recently to the Santa Fé train running from Santa Monica to Los Angeles. The locomotive struck a cow and the animal was thrown with great force against a telegraph pole a few feet from the track, breaking it. The broken pole fell toward the train, striking a car and crashing through the windows. Some of the passengers had a narrow escape from being cut by flying glass. The pole hit a brakeman, just missing his head. He escaped with ugly bruises.

A MOTOCYCLE FESTIVAL IN RHODE ISLAND.

Next September, at Narragansett Park, Providence, under the management of the Rhode Island State Fair Association, of which Mr. F. E. Perkins is President, a five days' motocycle exhibition will be given, with the accompaniment of races. No less than $5,000 is offered in prizes, and the conditions are to be drawn up very carefully so as to benefit the new art and industry as directly as possible. The races will take place on a track seventy-two feet wide, one mile in length, within grounds sixty-seven acres in extent. Last year the association spent $85,000, and its fair had an attendance of over 125,000 people.

MASSACHUSETTS TROLLEY SYSTEMS.

Robert H. Derrah, secretary to President Little, of the West End Street Railway Company, of Boston, has prepared an interesting map showing the extent of street railway in Massachusetts. Very few people understand that a continuous journey can be made from Gloucester, Mass., or Nashua, N. H., on street railway lines, not only to Boston, but through Boston to Brockton, and with the completion of lines proposed through Bridgewater to Taunton, to Fall River and Fairhaven upon the south shore of Massachusetts. The trolley lines also extend southwest to Milford, only a few miles from the eastern terminus of the Worcester street railway, now ending in Grafton, and with this gap filled a continuous trip can be made from Boston to Spencer.

Development on account of the electric road has been pretty extensive around Braintree and Brockton upon the south and Woburn, Wakefield and Beverly on the north. The valley of the Connecticut River has also developed a considerable trolley system of its own.

LITERATURE.

"SHOP KINKS AND MACHINE SHOP CHAT," by Robert Grimshaw, M. E. New York, 1896, N. W. Henley & Co. 393 pp., 5 x 8. Price $2.50.

This work, illustrated by over 222 engravings, is written in Dr. Grimshaw's best style. There is hardly any labor-saving "kink" which has escaped Dr. Grimshaw during his visits to the best machine shops in the country, and the work ought to be as valuable to the amateur as it must undoubtedly prove to the owner of a machine shop. We must commend the very full index which accompanies the work.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED APRIL 21, 1896.

Alarms and Signals:—

ELECTRIC GUEST CALL. S. K. Gimbel, Vincennes, Ind., 558,555. Filed Dec. 12, 1895.
Details of construction.

ELECTRIC ALARM SYSTEM. C. A. Rolfe, Chicago, Ill., 558,564. Filed Sept. 24, 1894.
Employs an auxiliary circuit for operating signal transmitting mechanism.

RAILWAY SIGNAL. W. G. Roome, Jersey City, N. J., 558,566. Filed Nov. 17, 1893.
Similar to above.

RAILWAY SIGNAL. W. G. Roome, Jersey City, N. J., 558,565. Filed Nov. 17, 1893.
Employs a main circuit comprising all the signals and a track circuit, in which the rails of one of the track sections is comprised.

ELECTRIC SIGNAL FOR RAILWAY TRAINS. E. J. Devine, Schreiber, Canada, 558,602. Filed July 25, 1895.
For description see The Electrical Engineer.

RAILWAY BLOCK SIGNAL. F. C. Stevens and J. Donovan, Lowell, Mass., 558,858. Filed Aug. 20, 1895.
Signal setting devices adapted to be actuated by the passing train, and an electric lock adapted to release said devices when the train passes from the block.

Storage Batteries:—

METHOD OF MANUFACTURING ELECTRODES FOR SECONDARY BATTERIES. I. Kitsée, Philadelphia, Pa., 558,692. Filed Nov. 8, 1894.
Consists in changing an electrolytically deposited lead surface through the action of heat in the presence of oxygen-containing material into a low oxide.

Conductors, Conduits and Insulators:—

WIRE CLAMP FOR TELEGRAPH OR SIMILAR WIRES. G. Middleton, Kirkwood, N. J., 558,509. Filed July 31, 1895.
Embodies a cam lever for tightening.

FASTENING INSULATOR BRACKETS. L. S. Beardsley, Naugatuck, Conn., 558,758. Filed Oct. 30, 1895.
A main portion, having its upper end screw-threaded for the reception of the insulator hood, and its lower end formed with lugs.

Dynamos and Motors:—

AUTOMATIC GOVERNING DEVICE FOR MOTORS. B. F. Merritt, Newark, N. J., and J. M. Joy, New York, 558,507. Filed June 29, 1895.
Provides means by which an electric motor may be started automatically and stopped by the depression and release of a key at a distance from the motor.

Electro-Metallurgy:—

APPARATUS FOR ELECTRICALLY WORKING AND WELDING COPPER. G. D. Burton, Boston, Mass., 558,480. Filed Aug. 11, 1893.
The conductors are connected to a converter and the electrodes are arranged to bear upon the bar to be treated.

Lamps and Appurtenances:—

APPARATUS FOR DETACHING ELECTRIC LAMP BULBS. O. Smith, Detroit, Mich., 558,573. Filed Oct. 7, 1895.
A flexible shaft provided with means for engaging the lamp, and means for rotating the shaft.

DROP LIGHT ELECTROLIER. G. Peeples, Philadelphia, Pa., 558,609. Filed Dec. 24, 1894.
An extensible bar or tube, adapted to slide within the central main tube of the electrolier.

ELECTRIC GLOW LAMP. E. A. Colby, Newark, N. J., 558,634. Filed May 21, 1894.
Obviates the use of supports for the inducing coil.

ELECTRIC STAND LAMP. R. Graves, Irvington, N. Y., 558,727. Filed Feb. 25, 1896.
Is intended to represent a candle or candelabra such as is usually employed on dining room tables.

ELECTROLIER. August Heck, Philadelphia, Pa., 558,904. Filed June 25, 1895.
Comprises a stand for table use.

Measurement:—

ELECTRIC METERING SYSTEM. J. W. Gibboney, Lynn, Mass., 558,585. Filed March 6, 1895.
A summation register adapted to separately add the units of meters after each unit is recorded.

Miscellaneous:—

CORE FOR ELECTROMAGNETS. A. G. Waterhouse, Hartford, Conn., 558,539. Filed Oct. 16, 1894.
Consists of a curved or annular magnet core, composed of ribbons or comparatively thin strips of iron rolled on one edge.

ELECTRIC HEATING. C. S. Bradley, Avon, N. Y., 558,714. Filed Aug. 22, 1891.
A conduit for leading the fresh air to the heater, a pipe for discharging it into an apartment, a pipe for discharging the air from the apartment over the walls of the conduit, by the means of two blowers.

PROCESS OF ELECTRICALLY TREATING FABRICS FOR WATERPROOFING OR OTHER PURPOSES. H. L. Brevoort, Brooklyn, N. Y., 558,717. Filed July 1, 1890.
Subjects the fibers to electrolytic action.

ART OF FIXING DYES IN FABRICS. H. L. Brevoort, Brooklyn, N. Y., 558,718. Filed July 25, 1890.
Consists in fixing dyes in fabrics by the use of metal oxides electrolytically deposited on the colored fibers.

ELECTRICALLY CONTROLLED GAS ENGINE OR MOTOR. G. L. Thomas, Montclair, N. J., 558,749. Filed Nov. 11, 1895.

Railways and Appliances:—

ELECTRIC STREET CAR MOTOR. S. Harris Cleveland, O., 558,491. Filed Feb. 10, 1896.
Each of the field coils is separately detachable with its core from the motor body and the body is separable in the plane of the armature shaft.

TROLLEY. J. H. Rabbitt, Wethersfield, Conn., 558,741. Filed Oct. 10, 1895.
A bar which is centrally pivoted to the free end of the trolley pole, and two contact wheels, which are respectively pivoted to the opposite ends of said bar.

MEANS FOR REVERSING TROLLEY POLE SUPPORTS. H. P. Wellman, Ashland, Ky., 558,868. Filed Sept. 17, 1895.
Employs pneumatic pressure.

TROLLEY FOR ELECTRIC RAILWAY CARS. H. P. Wellman, Ashland, Ky., 558,869. Filed Oct. 1, 1895.
Provides for the automatic lowering of the trolley pole immediately after the wheel jumps the wire.

ELECTRIC RAILWAY CAR. H. P. Wellman, Ashland, Ky., 558,870. Filed Nov. 5, 1895.
Similar to above.

Regulation:—

REGULATOR FOR ELECTRIC MOTORS. O. H. Pieper, Rochester, N. Y., 558,517. Filed Jan. 20, 1896.
The combination with a shunt wound motor, of a resistance in series with the field magnets, a resistance in series with the armature, and a branch containing a variable resistance between corresponding conductors of the field and armature.

ELECTRIC RHEOSTAT OR HEATER. H. W. Leonard, East Orange, N. J., 558,559. Filed Dec. 18, 1895.
Employs enamel for insulating the conductor and attaching it to the support.

MEANS FOR CONTROLLING ELECTRIC CURRENTS. P. Kennedy, Brooklyn, N. Y., 558,650. Filed June 27, 1895.
Especially designed for use in connection with dynamos employed to operate the lamps upon railroad trains.

Switches, Cut-Outs, etc.

HANDLE FOR CIRCUIT BREAKERS. W. B. Potter, Schenectady, N. Y., 558,518. Filed Jan. 15, 1896.
An interchangeable handle removable when the circuit is open.

APPARATUS FOR OPERATING ELECTRIC SWITCHES. D. Hinchliffe and A. D. Ades, Plymouth, Mass., 558,687. Filed May 15, 1895.
Means for operating a switch by push buttons placed in any part of a building.

MULTIPLE CONTACT SWITCH. E. H. Wright, Chicago, Ill., 558,750. Filed Nov. 28, 1894.
Adapted for use on three-wire systems.

Telegraphs:—

PRINTING TELEGRAPH. B. F. Merritt, Newark, N. J., and J. M. Joy, New York, 558,506. Filed June 29, 1895.
Consists in mounting the type wheel carriage on rollers and journaling the type wheel and the worm on this carriage.

TELEGRAPH KEY. W. E. Simons, Dublin, Canada, 558,617. Filed Sept. 12, 1895.
Means for insuring the closure of a telegraph key when the same is not in use.

RELAY. F. E. Chapman, Medford, Mass., 558,672. Filed Jan. 27, 1896.
Employs the current in one winding of an induction coil to magnetize the armature and the induced current of secondary winding of the coil to move the armature.

Telephones:—

TELEPHONE. S. D. Field, Stockbridge, Mass., 558,584. Filed Aug. 24, 1895.
For description see The Electrical Engineer, April 29.

TELEPHONE TRUNK CIRCUIT. W. H. Hennessey, Chicago, Ill., 558,686. Filed Feb. 7, 1896.
For long distance use.

TELEPHONE APPARATUS. A. Stromberg and A. Carlson, Chicago, Ill., 558,859. Filed Oct. 9, 1894.
Details of construction.

LEGAL NOTES.

OTTO GAS ENGINE PATENTS.

The Otto Gas Engine Works of Philadelphia have issued the following notice:

We think it fair to you, as well as to ourselves, to advise you that we are informed by our counsel, Messrs. Baldwin, Davidson & Wight, of Washington and New York, that the electrical igniter on the gas and gasoline engines of the New Era Iron Works Company is an infringement of Letters Patent of the United States, No. 525,828, granted September 11, 1894, to Mr. Paul A. N. Winand, and of which we are the owners. We have brought suit in the Southern District of Ohio against the New Era Iron Works Company and propose to protect our rights against all makers and sellers or users of engines having upon them igniters covered by such Letters Patent.

THE NATIONAL CONDUIT MANUFACTURING CO. SUSTAINS ITS PATENTS IN THE COURTS.

A decision was rendered recently by Judge Townsend, in the United States Court, District of Connecticut, sustaining the patents of the National Conduit Manufacturing Company in their suit against the Connecticut Pipe Manufacturing Company. The decision enjoined the Connecticut company from infringing the patents on the well-known cement-lined tubes, which patents are owned and controlled by the National Conduit Manufacturing Company.

Last week Judge Townsend, on the application of the Connecticut Pipe Manufacturing Company, decided to reopen the case, and we learn that, pending final decision, the latter company will continue the manufacture of cement-lined pipe as heretofore.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE MANHATTAN INCLOSED ARC LAMP.

THE Manhattan inclosed arc lamp has been commercially on the market for one year and a half, during which time the Manhattan General Construction Company gradually built up the reputation of inclosed arc lamps to such a degree that the principle of inclosed arc lamps is now acknowledged to be correct.

Since starting the company have placed in service up to the present time about 7,000 Manhattan lamps, and have had the lamp adopted by 100 direct current central stations. Of course, the adoption of the lamp by all of these companies was after thorough tests under every possible condition of service, and the growth of the business is extending month by month.

The main features of the Manhattan lamp—which is illustrated in the accompanying engraving—outside of saving in operating are, first, the possibility of drawing an arc at 80 volts, making it possible to burn lamps singly, instead of two in series, as was necessary with open air arc lamps. The advantage of each lamp being an independent unit, will, without doubt, do much toward extending the use of incandescent arc lamps in all kinds of service. The arc being inclosed within two practically air tight globes prevents the throwing out of sparks and carbon dust, and makes the lamp particularly desirable from the underwriter's standpoint.

THE MANHATTAN INCLOSED ARC LAMP.

Perhaps the most attractive feature of the inclosed arc lamp is the diffusion of light obtained by the use of the double opalescent globes. The inner globe diffuses the light on the outer globe and removes absolutely all shadow from the outer globe as well as beneath and above the lamp, and makes a space lit with Manhattan lamps a perfectly uniform light, and the long arc eliminates all the yellow rays, and produces an effect nearer to true daylight than any artificial light that has yet been offered.

The inclosed arc at once necessitated an entire new style of mechanism. The mechanism of the Manhattan lamp has done away with all clockwork, carbon rods, dash pots, and the like, and is nothing but a solenoid with an armature and simple ring clutch. The carbon feeds direct without the intervention of a carbon rod, which in addition to overcoming the difficulties incident to a carbon rod, allows of the shortest arc lamp that has ever been put on the market. The Manhattan "Standard" lamp, using 12-inch upper and 5-inch lower carbon is only 37 inches long, while their "Junior" type of lamp, using 12-inch upper and 5-inch lower carbon, is only 23 inches long over all.

In regard to the matter of saving of carbons; after burning for 150 hours there is sufficient left of the upper carbon to use for a lower carbon for the next run, so that on the basis of 10 hours per day the cost of carbons for one year with the Manhattan lamp (at $25 per 1,000 12-inch carbons) will not exceed 50 cents per lamp per year, whereas in commercial work where the average burning of lamps is less than 4 hours per day, the lamp will only require for 300 days service about 8 carbons per year or 16 cents per lamp per year for carbons.

In regard to saving in labor, it is, of course, governed by the service in which the lamps are used, and their distribution. Theoretically, there would be almost the same proportionate saving in labor as in carbons, but in practice it is found the saving on the average is about two-thirds, so that the saving on commercial and street lighting service might be given at from $10 to $15 per lamp per year as a minimum.

The best figures in the way of verification in the above deductions from the Manhattan Company's experience are as follows: The Brooklyn Edison Company have made up figures on the saving from 350 Manhattan lamps which they use in street lighting service, and they report a saving of about $15 per lamp per year, although this saving shows somewhat in the lamp's favor for the reason that 100 of the Manhattan lamps displaced twin street lamps, taking, of course, more carbons, although smaller than the single lamps.

The Boston Edison Company have 200 Manhattan lamps in commercial service. They report an average burning of 3.64 hours per lamp per day, and figure a saving from between $11 to $12 per lamp per year.

Profs. Houston and Kennelly have made a test on the candle power of the Manhattan lamp, and also examined the diffusion of light. These show that the long arc in the Manhattan lamp changes considerably the old formulas of taking all measurements at an angle of 40 deg. below the horizontal. In the column of luminous intensity, we note that the maximum angle of light is about 25 deg. and that it then drops off and rises again at about 45 deg. This was caused by the curve on the inner globe used at the time of this test, but the shape of the inner globe has since been changed so that the curve of the angle of light is now practically uniform from 25 to 60 deg., thus giving a diffusion of light over a very extensive radius.

It might be well to add a word in regard to the efficiency of the inclosed arc lamp, as many seem to not be able to figure correctly and comparatively between the inclosed arc lamp burning singly and the ordinary open arc lamp burning two in series, on account of the fact that the inclosed arc lamp takes only one half the current of the two in series lamp. With Manhattan lamp on a 110 volt circuit, there is a permanent resistance taking up from 28 to 30 volts, which at 5 amperes makes 140 to 150 watts consumed in the resistance. In open air arcs there is a permanent resistance absorbing 13 to 15 volts in each of the pair of lamps running at 10 amperes, or there is consumed in the resistance from 260 to 300 watts for the pair, or 130 to 150 watts to each lamp, so that it will be seen that the efficiency of inclosed and open air arc lamps is practically the same.

One of the main features of the Manhattan lamp is the fact that there are employed double globes, both of which are practically tight. The outer globe being entirely inclosed, of course, acts as a thorough protection against weather, but in addition the outer globe acts as a storage chamber for the inner globe or chamber of high rarefaction, and makes the egress of air containing oxygen into the inner globe and to the carbons, very slow.

THE ELECTROSE MANUFACTURING COMPANY, now situated at 216 William street, New York, are again compelled to seek larger quarters, owing to the constantly increasing demand for their wares, and will remove May 1 to 127-137 North Tenth street, Brooklyn, N. Y. They will have there some 13,000 square feet of floor space, and with a larger plant will be in position to meet promptly all calls for the substitute for hard rubber.

THE Government of Japan, Department of Communication, has written to the Standard Air Brake Company, requesting that company's literature.

FAN MOTORS are the subject of Catalogue No. 16, just issued by that brainy and pushing concern, the Central Electric Company, of Chicago. It is full of cuts and data.

THE AMERICAN ELECTRIC VULCANIZER.

THE bicycle has called into life a multitude of devices designed either for the ease and comfort of the rider or as auxiliaries in effecting repairs. The rubber tire is perhaps the most vulnerable part of the machine, and damage to it has in the past usually demanded a new tire. Thanks to the introduction of electrical heating devices this is no longer necessary. The electric vulcanizers which are shown in the

FIG. 1.—THE "AMERICAN" ELECTRIC VULCANIZER.

accompanying engravings, which are the latest designs of the American Electric Heating Corporation, of Boston, puts it within the power of any ordinary repair shop to put a punctured or ruptured bicycle tire in a condition practically as good as new.

As will be seen, the machine may be set up on any substantial table or work bench, and a space of two by three feet is ample. The tire is clamped to the plate of the vulcanizer under a pressure of about fifteen pounds, and the illustrations show the different methods by which this is accomplished. Several tires can be repaired at one time. The temperature of the plate is controlled by a rheostat or switchboard on the end of the machine, the heat being applied by turning the switch to the

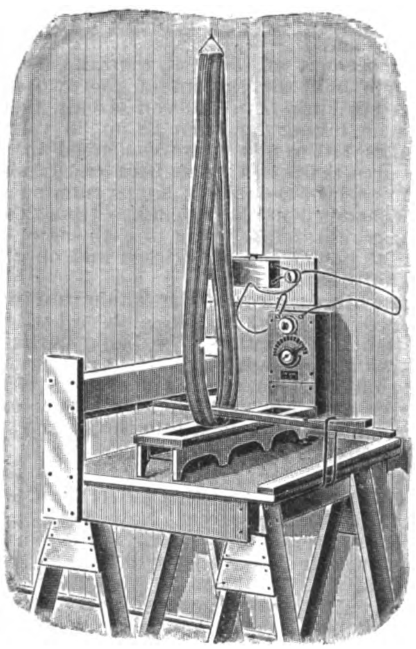


FIG. 2.—THE "AMERICAN" ELECTRIC VULCANIZER.

right, and each successive turn from left to right increases the amount of heat applied to the plate. The proper temperature can be determined accurately by curing a piece of uncured rubber.

These vulcanizers are made in two sizes, the smaller, type A, Fig. 1, suitable for the average repair shop, and type B, Fig. 2, with two plates, adapted specially for larger repair shops.

KENSINGTON FEED WATER HEATER AND PURIFIER AT THE PHILADELPHIA BOURSE.

IN the engravings on this page we present two views of a feed-water heater and purifier furnished by the Kensington Engine Works, Limited, Francis Brothers, Philadelphia,

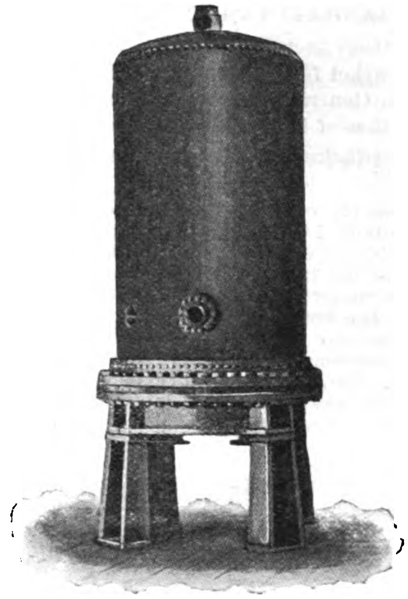

FIG. 1.—THE KENSINGTON FEED WATER HEATRER.

Pa., for the recently completed Philadelphia Bourse. It is attracting considerable attention from visitors viewing the mechanical exhibition in the Bourse as furnished by the machinery used in the building.

About 18,000 square feet of space is occupied in the basement by the machinery equipment, and the chief interest centers in the power and heating plants, of which this heater, probably one of the largest in diameter ever built, is an important factor. The heater is 60 inches in diameter, with shell 14 feet high over all, and has exhaust steam inlets and outlets 16 inches diameter. It is provided with 350 square feet of heating surface and heats the feed-water used in the boiler

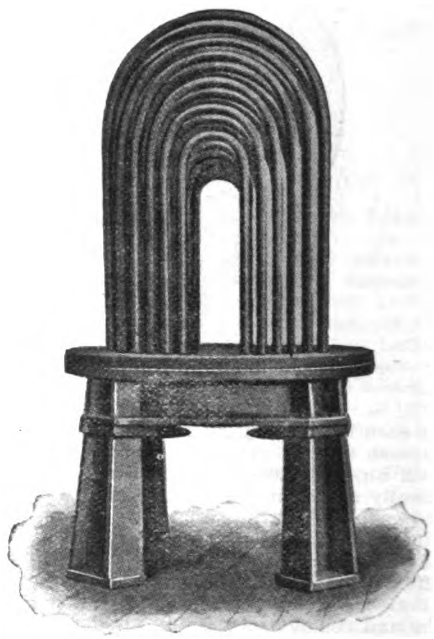

FIG. 2.—THE KENSINGTON FEED WATER HEATER.

supply to 206 deg. by the exhaust steam from the electric light engines and pumps, while also purifying it.

The heater is of the reservoir type, return tubular, and has a capacity of 1,250 gallons. The exhaust enters at the bottom, and, passing through the tubes on one side, returns through the tubes on the opposite side, while the feed-water

is in the shell surrounding the tubes, thus absorbing rapidly the heat in the exhaust steam.

While the general construction of this heater is largely explained by the engravings, a few words regarding the details are of interest. There is first a cast iron base with projecting flanges on the top and suitable flanged nozzles on the bottom for the ingress and egress of the steam, and projections properly ribbed and braced are also provided for the reception and bolting to of the four cast iron legs which support the heater at a suitable height from the floor.

Resting upon the top flange of the bottom casting is the tube head made of semi-steel, similar to that used by the Cramps in guns, which is made convex in order the better to withstand and resist the pressure required to force the water into the boiler, which is 125 pounds per square inch.

The tubes, which are of seamless brass and therefore free from corrosion and very durable, are securely expanded into this tube head, and when so done the tube and tube head becomes practically one piece or part of the apparatus.

The shell, which is of wrought steel ½ inch thick, is designed to inclose the tubes and at the bottom end has a strong cast ring securely riveted to it, with projecting flange corresponding in diameter to the flange of bottom casting and tube head. The bolt holes of all three being identical in the matter of spacing and pitch circle, one set of bolts, with proper gaskets intervening, the whole three parts of the heater are firmly bolted together.

Feed-water enters and leaves the heater by a 4½-inch pipe, and all impure deposit is blown out through a 3-inch mud blow at the bottom, while the impurities which float on the surface are removed through a 2½-inch surface blow. The connections provided are shown as located on the shell in Fig. 1.

A feed-water heater of the same diameter and general construction is installed by the Kensington Engine Works, Limited, in the power plant of the Broad street station, Philadelphia, where it has given most safisfactory results.

THE NORTHERN ELECTRICAL MFG. CO'S MOTORS.

AMONG the recent additions to the types of dynamo electric machinery are the motors of the Northern Electrical Manufacturing Company, of Madison, Wis. These machines are inclosed in very strong, steel spheres without joints so that attachment may be made of the motor to any other machine in almost any conceivable position and have as firm connection as though attachment were made from the base of the machine as is ordinarily done. The machines can be used with or without bases; they are so constructed in their bearings that they run as well upside down, fastened to the ceiling; or half inverted bolted to a post or side wall, thus saving the floor space which would ordinarily be occupied by the motor. It makes no difference what direction the draught of the belt is from, the bearings work equally as well.

That feature of the machine which enables it to be inverted renders it a very convenient machine for direct attachment to line shafts, the motor being inverted and bolted up to the ceiling in the same position as an ordinary hanger. A line shaft, or main shaft of any particular machine, may be directly connected to the motor shaft. The Northern Company also have a geared attachment to be used in some cases where the direct shaft attachment may not be practicable.

The company are making a specialty of motors, dynamos and electric hoists, to which they confine themselves exclusively.

STANDARD TELEPHONE CABLES.

The very satisfactory results which may be attained by earnest and systematic efforts to improve the quality of the manufactured article is strikingly illustrated by the character of the cables furnished by the Standard Underground Cable Company at the present time for telephone use.

A recent large order for the American Telephone and Telegraph Company, of Providence, was sold with a guarantee of 500 megohms per mile insulation resistance, and a capacity of .08 microfarad per mile. The tests of these cables by the electrician of the Providence company disclose the remarkably low average capacity of .0743 and .0749 microfarad per mile. The highest capacity of any wire in the cable was .0776, and the lowest .0716, showing a high degree of uniformity. The insulation resistance of the wires averaged 1,933 megohms and 3,300 megohms per mile, respectively.

The Standard Underground Cable Company, as well as the American Telephone and Telegraph Company, are certainly to be congratulated on this truly remarkable showing.

MESSRS. HERRICK & BURKE, consulting engineers, have removed their offices to the American Tract Society Building, No. 150 Nassau street, New York, where they will have increased facilities for carrying on their work.

THE HELIOS ALTERNATING LAMP WIRING TABLE.

WIRING tables for incandescent lamps have been current for years, but, strange to say, arc-lamp wiring seems to have been entirely neglected. It must be evident, however, that when it comes to installations of arc lamps on constant potential circuits involving anywhere from a dozen to one hundred or more arc lamps, some system is necessary to

obtain economy in wiring. The Helios Electric Company, of Philadelphia, have therefore done the electric fraternity a good service in compiling a table specially covering the wiring of alternating current arc lamps. The table which we reproduce herewith is calculated on a 30-volt basis, but can, of course, be readily converted to any other basis by introducing the proper multiplier.

NEW WESTERN ELECTRIC FACTORIES.

The Western Electric Company have just completed a new factory in Chicago at a cost of $125,000, and are preparing to build another to cost an equal amount.

The structure nearly completed extends from No. 242 to No. 248 Jefferson street, and is 180 feet front by 50 deep. It is regarded as one of the most completely fireproof manufacturing buildings in Chicago. With metal partitions and steel construction throughout it is practically beyond the reach of flames. Not a particle of wood his been used in the construction, excepting for finishing. The building is equipped with automatic sprinklers. A novel feature is the use of numerous bays on the west side, giving ample light for the workmen and following the lines of the most sanitary manufacturing buildings.

The proposed building, for which plans are being prepared, will correspond in its general construction with the building recently completed. It will take the place of a number of old buildings in the center of the company's plant, and will be 50 x 100 feet, with two wings 40 x 60 feet.

In this structure will be placed the boilers and engines, which will provide power for the entire plant. A new system of electrical power transmission with individual motors for the different rooms is being placed in all the buildings of the plant, and will save much of the energy wasted in the transmission of power by heavy shafting. Work on the building, for which Treat & Folz are making the plans, will be commenced in the summer.

CHANGES IN STANDARD UNDERGROUND PERSONNEL.

As stated in our former numbers, the Standard Underground Cable Company have been making a number of changes in the personnel of their home office, in order to handle the large increase in their business. Mr. Frank C. Cosby, formerly of the engineering staff of the Westinghouse Electric and Manufacturing Company, at Pittsburg, has taken the place left vacant by Mr. F. S. Viele's transference to Pittsburg, and goes to Chicago as superintendent of construction. Mr. Cosby graduated from Cornell University as an electrical engineer in 1893, and has since been actively employed in electrical work, and during the World's Fair was electrician to the U. S. naval exhibit on the model battleship "Illinois." He will prove an able assistant to Manager J. R. Wiley in taking care of the constantly increasing business of the Standard Underground Cable Company in this territory.

Mr. Cosby has just returned from Columbus, Ohio, where the Standard is installing the underground cable system for the Central Union Telephone Company.

MR. JAMES McLAUGHLIN, recently with the Philadelphia Engineering Works, Limited, has been elected secretary and treasurer of the Barr Pumping Engine Company, of Philadelphia. Mr. W. W. Lindsay is the General Manager of the latter concern.

FISHER AND CRAMPHORN.

This is the name of a new company who are going to manufacture electrical specialties at 355 Congress street, Boston, Mass., the old factory of the Consolidated Electric Manufacturing Company, which company was absorbed by the Walker Company, of Cleveland, a few weeks ago. Messrs. Fisher and Cramphorn are both well known to the electrical trade, Mr. Fisher having been connected with the Consolidated Electric Manufacturing Company for many years as their factory manager, and Mr. Cramphorn having been in charge of their business department for the past few years. This company will continue to manufacture the well-known "J. K." switches and switchboards, and have the sole right to manufacture the "Lyon" brake handles, which have established for themselves an excellent reputation among street railway men. Both Messrs. Fisher and Cramphorn are well posted as to the necessities for reliable apparatus in all electrical business, and their long experience in this trade should enable them to manufacture just the class of material required, and with the numerous friends which they have made in past years, success will undoubtedly crown their efforts.

SOMETHING NEW IN JACK-KNIFE SWITCHES.

The Electric Engineering and Supply Company, of Syracuse, N. Y., are again in the field with an improved jack-knife switch, of which some of the cuts herewith give an idea of the construction of the arm. It will be noticed by careful examination of the arm that it is made in sections by a principle which the company have had patented, being something entirely new applied to electric switches. The backbone of the arm is made of brass tube slotted to receive a copper blade, held in by patent process of plugs and nuts, making a secure and strong arm, as well as securing a good flexible contact to the contact clips.

A number of these switches are already in use on some of the principal switchboards in New York City, Buffalo and other cities. The company are now building some seventy-five of these new style switches to be placed on the switchboard in the new Siegel-Cooper Building in New York City. Notable among the boards in New York City on which these switches are used are the following: One installed by the St. Nicholas Skating and Ice Company, West Sixty-sixth street; the Vance Electric Company, 65 Murray street, and Edwards & Company, southeast corner Clinton and University place. The handsome appearance of these switches is what makes them a favorite with switchboard men, as well as their unusually good adaptabilities for switchboard use, as to bus-bar connections. They are made for either back or top connections, adapted for any voltage.

THE G. E. 150 HOUR ARC LAMP.

Arc lamps for constant potential continuous circuits, designed to burn 150 hours without retrimming, and a shorter lamp of similar design to burn 100 hours without retrimming have just been announced by the General Electric Company. These lamps require about 5 amperes at 80 volts, a resistance adjustable for voltages of 150 to 120 contained in the lamp, reducing the normal voltage of a lighting circuit to that required by the lamp. The lamps are sent out adjusted for 110 volts. By confining the arc in a sealed globe an inert gas is formed, reducing the consumption of carbon and securing longer life. The mechanism of the lamp is simple, requiring no adjustment.

The color, volume and character of the light are varied by using different inner and outer globes. A dense opal inner globe and opalescent or ground glass outer globe give the effect of the glow lamp, with less volume of light, while, where the appearance of the light is not objectionable, an opalescent inner globe and a clear outer globe may be used, securing a larger volume of light.

THE WALKER MANUFACTURING CO.

That many of the large companies that manufacture electrical goods have suffered severely during the recent general depression in trade is a matter of which there cannot be any doubt. Happily there is now a brighter outlook on the business horizon and it is to be expected that the important electrical industries will be early benefited by the revival. One sign of a healthy reaction in this direction is furnished by the following list of contracts for street railway apparatus, which the Walker Manufacturing Company of Cleveland have closed quite recently: Chicago City Railway Company, five 800 kilowatt belt driven generators; Metropolitan Railway Company, Kansas City, one 1,200 kilowatt direct connected generator; Englewood and Chicago Electric Railway Company, four 250 kilowatt direct connected generators, twenty-three car equipments which will comprise a 50 h. p. motor and a Walker controller to each car; Bluff City Railway Company, Waukeegan, Ill., three double 30 h. p. equipments. These contracts were secured through the Chicago office of the company, of which the Messrs. Koehler Brothers are managers. Naturally to be expected there was quite a sharp competition for these orders, as they represent in the aggregate over 9,000 h. p., and they were all closed inside of two weeks, which is an unusually short time when the magnitude of the business is taken into account.

GENERAL MANUFACTURERS' DISPLAY BUREAU.

Messrs. Edwards Bros. & Company, of 90 and 92 West Broadway, New York, have organized "The General Manufacturers' Display Bureau" for the purpose of interesting those manufacturers located outside of New York City who are desirous of having: 1. First class representation of their product in this city. 2. Facilities for having out-of-town buyers brought in contact with a personal inspection of their products. 3. The advantage of being able to show a complete line of samples to the trade of their manufacture or output.

The firm's offices and sample rooms have been selected with great care, and are located down town, in the center of the wholesale district, convenient to every class of buyers who visit New York regularly, and seldom, if ever, have the time to go to other cities.

Each member of the firm is a first class salesman, and their acquaintance amongst the buyers of the United States, together with the facilities they have at their command for reaching them as they come to town, are unlimited. They now have over 38,000 square feet of space, combining light, ventilation, and all modern conveniences, with the option of as much more room as may be required.

QUEEN & COMPANY.

A banquet was given recently at the Manufacturers' Club, Philadelphia, by the stockholders and creditors of the celebrated old house of Queen & Company, Incorporated, as a testimonial to Mr. John G. Gray, who at the time of the panic was appointed receiver of the concern. Mr. Gray has redeemed the company and re-assigned to it the property with a generous surplus of $200,000. In the reorganized firm the officers are: J. G. Gray, president; S. L. Fox, vice-president; and J. M. Hazel, secretary and treasurer.

ELECTRICAL AND SCIENTIFIC INSTRUMENTS.

Mr. James G. Biddle, No. 944 Drexel Building, Philadelphia, is quietly but surely building up an excellent business in scientific and electrical instruments. As sales agent for the Weston Electrical Instrument Company, Mr. Biddle makes a leading specialty of the voltmeters, ammeters, and wattmeters of this standard type, and is always ready to quote prices or furnish special information regarding them. His compact illustrated Catalogue X is much in demand—containing a complete price list of Weston apparatus, and also valuable data for resistance measurements.

Mr. Biddle is also distributing agent for Messrs. Elmer G. Willyoung & Co., of Philadelphia, manufacturers of electrical test instruments and scientific apparatus. To describe their various instruments Mr. Biddle has just issued circulars No. 135, 160 and 165, which should be written for at once by interested parties.

MESSRS. C. C. SIBLEY & COMPANY, selling agents for the General Electric Company for New York City, will remove their offices on May 1 from the Postal-Telegraph Building to their new store at No. 329 Fourth avenue, between Twenty-fourth and Twenty-fifth streets. This firm has decided that in order to better serve the trade they should keep pace with the northward march of business in New York. They will carry a full line of contractors' supplies, including interior conduit, bell and annunciator supplies. They are looking forward to a big sale of Lundell fans this season and will be prepared to fill promptly all orders for them.

THE ABENDROTH & ROOT MANUFACTURING COMPANY, 28 Cliff street, New York City, have closed contracts for their Root improved water tube boiler for the electric light and power plant of the East River Bridge, Munsey's new building and the Electrical Exposition, New York City.

THE BALL ENGINE COMPANY, Erie, Pa., have removed their Chicago office to the Monadnock Building, Room 1526.

Department News Items will be found in advertising pages.

Vol. XXI. MAY 13, 1896. No. 419.

ELECTRIC LIGHTING.

EQUALIZER SYSTEMS OF DISTRIBUTION.[1]

BY A. CHURCHWARD.

IN preparing the following paper, the limited scope of which is indicated by its title, I have assumed that a three-wire system is supposed to be the only safe and reliable system of direct current distribution for motors and lights in our cities. It is my intention to refer to the many methods that have been devised to accomplish the results obtained by the three-wire system, without the use of a divided source of electrical energy, and a compensating conductor

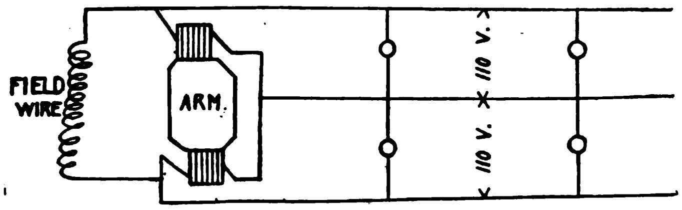

FIG. I.

connected to the point of division. I now lay before you an abbreviated list of such methods.

1. Using a single dynamo with two commutators: Very little would be gained by this even if it did not infringe the above system, as one commutator on a large machine is all most people can put up with. Fig.1.

2. I do not think that at this late day any one is likely to try the combination of a 220 volt dynamo and two sets of lamps connected in series by a third wire. Fig. 2.

3. This time we come to a true system of equalizer distribution. We have only one generator of, say, 220 volts, A, Fig. 3, and two small machines, C and D, capable of taking care of the unbalance due to turning off lights on either side of the circuit; and a motor, B, connected to the two outside mains and driving the two machines, C and D.

In this system our comparative loss is quite great at light loads, as we have a constant loss due to the friction field current, and Foucault currents of three machines. Another disadvantage is the difficulty in keeping the system properly balanced, owing to drop in speed of motor with increase of load, drop in voltage of one of the machines, C or D, when running as a dynamo (due to armature reaction and C^2R losses in the

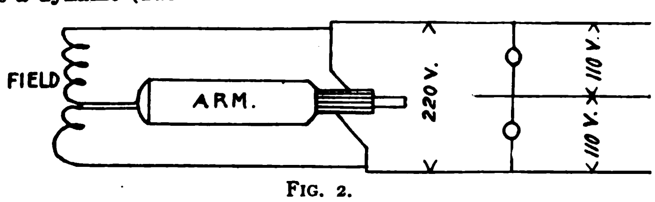

FIG. 2.

armatures); and, on the other hand, the load being taken off, the voltage will be taken off on the lightly loaded side.

The action that takes place is this, and will be found nearly the same in all equalizer systems.

When both sides of the circuits E and F are equally balanced, the motor B runs free, only taking enough current to keep C and D up to the proper e. m. f. Should the load be changed, however, so that F had 20 amperes and E 10, then there would be unbalance of 10 amperes.

An ammeter placed in the circuit at G would indicate 15 amperes plus the amount of current to run combination B, C and D. Fifteen amperes would flow from the main (F) M to N, and the machine D would act as a dynamo and supply the

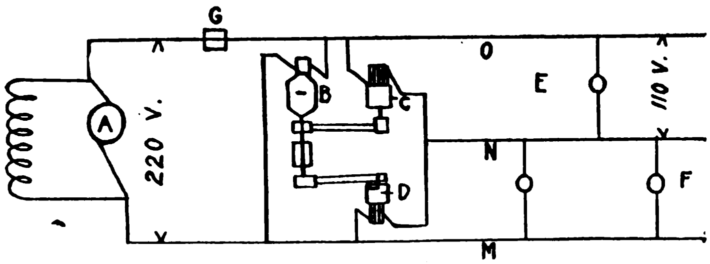

FIG. 3.

other five amperes. On the other hand, the machine C would take the five amperes from the neutral N, and run as a motor, helping to drive the motor B.

Thus it can be seen that under ordinary conditions we can dispense with the motor B and couple C and D together, as per diagram. But by using the motor B, a greater load on one side can be taken care of.

4. A single dynamo, 220 volts, A, Fig. 4, and a small machine of 110 volts, C, driven by a motor, B, connected across the 220 volt mains. The motor B drives the machine C so that the pressure across E and F are equal; should the load be

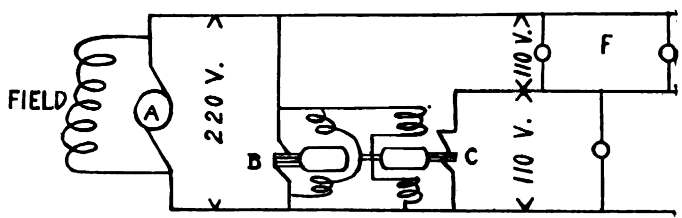

FIG. 4.

increased on E, the pressure will fall, and the machine C will supply the extra current needed to balance the pressure; if the load on E is less than on F, then C will run as a motor, driving B as a dynamo. In this case also there will be a slight unbalance of pressure, due to armature reaction, etc.

5. Still another method has been proposed. This employs a single dynamo of 220 volts. To the brushes of this machine are connected the two outside wires, the neutral wire is connected to the center of the armature coils, and this raises a potential midway between the two outside wires.

6. A system in use in central stations in Europe might

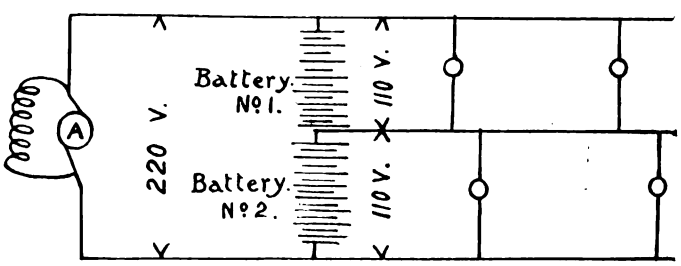

FIG. 5.

be mentioned here, but we can hardly call it an equalizer system. It consists of a 220 volt dynamo and two sets of batteries, Fig. 5. The accumulators here play the same part as their namesakes do in a system of hydraulic supply. The bat-

* Read before the N. E. L. A., New York, May 5, 6 and 7, 1896.

tery connected to the circuit that requires most current discharges into the circuit, and thus helps the dynamo; and the battery in which the demand is smaller is charged by the surplus current.

There is no economy in an installation by this method over

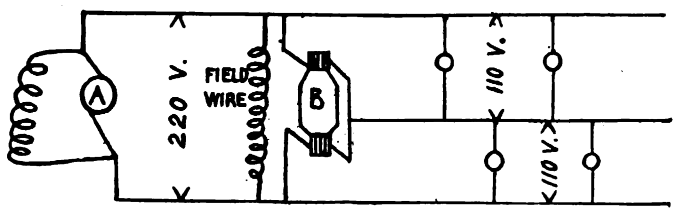

FIG. 6.

others, the accumulator costing much more than a rotary equalizer. We gain this much, however: during the hours of light load the batteries may supply all the current required, permitting the shutting down of the central station during those hours.

7. I intend now to bring to your notice an equalizer that has passed the experimental stage and has been in operation day and night for two and one-half years; no lamps have ever been lost owing to lack of balance of the system. Again, we only require one generator, A, 220 volts, and one small machine with two commutators, B, Fig 6. We have only two bearings to worry about. Only one field loss; one loss due to hysteresis and eddy currents; and absolutely no armature reaction. There being no armature reaction, there will be no drop in speed, no sparking at the brushes with a change of load, and the capacity of the equalizer will be the heat limit of the armature winding.

By using the equalizer system, we have one unit, or set of

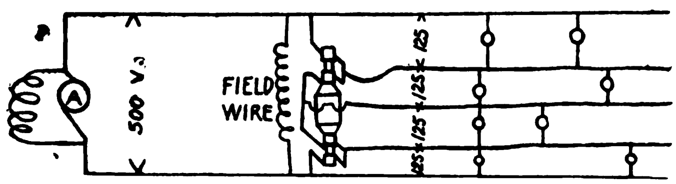

FIG. 7.

units, running at a high efficiency, and for a reserve we have only one machine. It is not limited to only 220 volts. Where a company has a motor trade much scattered, they can take, for instance, 500 volts and run a good distance with economy, then put an equalizer in a central location and supply your customers with lights at 110 to 125 volts, Fig. 7.

Or, again, we want light and power in one unit. We can take one generator, 50 kilowatts, 250 volts, and a motor of 50 horse-power, but with two commutators; or, in other words, on a 50 horse-power equalizer we can take either the full load in power off the pulley or the full number of lights off one side at 110-125 volts, or in any proportion we see fit.

Still another advantage of this system: we can always compensate for the drop in our line at any point independent of all others. This we might call a booster equalizer system. When the heaviest loads are on our system and the sides balanced, all the equalizer does is to run free as a motor. Now,

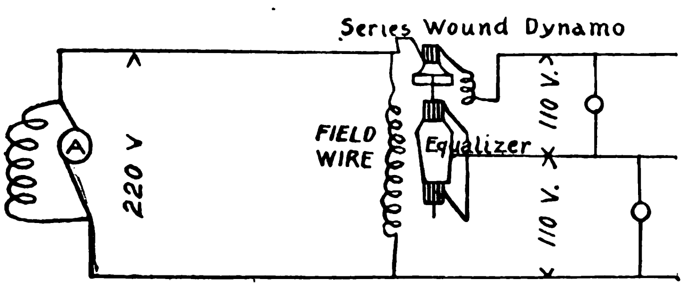

FIG. 8.

by attaching a small series wound dynamo to the end of the shaft of the equalizer, and adjusting it to the load and drop, we will first boost our pressure and then equalize it. So that, given a district with various points of distribution and various drops, we can run even the longest and heaviest loaded circuit at the same pressure as our station e. m. f., Fig. 8.

RESULTS ACCOMPLISHED IN DISTRIBUTION OF LIGHT AND POWER BY ALTERNATING CURRENTS.[1]

BY W. L. R. EMMET.

The introduction of successful polyphase motors has constituted a very radical and important step in the development of the electrical art. The number of persons who realize the importance of this step is as yet small, and, like other new things, it can not attain great successes until its merits and possibilities become more or less familiar to the public and to the practical business men on whom the responsibilities for new developments must largely rest. In the past, the use of alternating currents has been almost exclusively for incandescent lighting, and this narrow limitation has crippled the development of the art. While the applications of direct currents have called forth very large investments in plants and distributing systems, the uses of the alternating current have, as a rule, been on a much smaller scale, and the methods used have been developed rather with a view to reduction in first cost, than to the attainment of the most economical results in operation.

The reasons for this somewhat half-hearted development may be stated as follows: First—The average efficiencies attained in most alternating plants have been very low. Second—The distribution of potential obtainable with the ordinary methods has been imperfect. Third—No reliable alternating arc lamps have been available. Fourth—No practicable form of single-phase alternating current motor has, up to the present time, been introduced.

At no time have all these difficulties been entirely unavoidable in alternating current distribution; they have, however, been fixed features of the system as it has in the past been installed by our manufacturing companies and used by electric light companies in this country; the state of the art being such that improvements were beyond the reach of most central station managers.

In recent years great developments have been in progress in the branches of electrical science pertaining to alternating currents; much new apparatus has been developed, plants have been installed on new lines, and practical results are to-day being accomplished that show that it is possible to overcome all of the objections which have been mentioned.

We will briefly review in order some of the means by which the difficulties mentioned have been and can be avoided.

EFFICIENCY.—The greatest losses in the average alternating plant are due to the waste in iron cores of transformers, which goes on whether the transformers are loaded or not. This waste can be reduced, either by the use of transformers of high light load efficiency, or by arrangements for cutting out transformers at light load.

Where primary distribution is used with large numbers of independent transformers, the extent to which these remedies can be adopted is very limited, since reduction of core loss can be obtained only at the expense either of regulation or of first cost. If, however, secondary distribution is used, that is, low-tension mains with transformer sub-stations, it is often possible to arrange means of cutting out transformers at times of light loads. Furthermore, on such systems very accurate regulation in transformers is a matter of no importance, since all transformers divide the load more or less evenly between them, instead of operating from the same line at various conditions of load as in primary distribution. Thus, for this secondary work, we can built special transformers having very small core losses and thus obtain very high all-day efficiency without impairment of regulation.

I have in mind a large plant now being equipped with alternating apparatus for lighting and power distribution on thoroughly modern and improved lines. In this case a system of three-wire, low-tension mains is to be laid over a large area. These mains will be fed at street corners from specially designed transformers in ventilated manholes. These transformers are to be of 100 kilowatts each, and are to have a core loss of only 500 watts, or one-half of one per cent of the capacity. The efficiency of these transformers at one-quarter load will be higher than at full load, the principal loss being in the copper. Thus a transformer may be made to fill the same functions as a direct current feeder. If we are willing to introduce some drop between generator and main, we can get high light load efficiency with moderate cost, and we shall retain the important advantage that transmission is possible over long distances, with small losses, through the use of high voltage.

REGULATION.—The cause of bad regulation in most existing alternating plants is that each individaul installation is connected to a separate transformer, and that in these transformers, and the wiring connected to them, there are losses varying with

[1] Read before the N. E. L. A., New York, May 5, 6, 7. Abstract.

the load, which, of course, can not be controlled from the station. Since regulation is a matter of most vital importance, we see that with primary distribution good regulation in transformers is imperative. To make transformers of specially good regulation, something must be sacrificed, either in economy of first cost, or in light load efficiency, or in both. Thus there is always an appreciable drop through resistance of wire in transformers, and this, combined with the drop in primary and secondary wiring, gives rise to serious vibrations in pressure on lights at different points.

Another fruitful source of potential variations on alternating circuits is found in the self-induction of circuits and also in the self-induction of transformers. The electromotive forces introduced by self-induction being out of phase with the current, are variable in their effect, and give rise to troubles that sometimes seem erratic, although in reality they are governed by well defined laws, which, if properly observed, enable us to obtain accurate results.

MOTORS.—Until very recently the operation of motors from alternating systems has been practically out of the question, since no suitable motor has been obtainable. Thus alternating apparatus has been available only for lighting, while in direct current stations motor load during the day has been a most important source of profit. It may be mentioned here that while incandescent lighting is at the present time meeting sharp competition from other forms of illumination, the electric motor is growing very rapidly in popularity. It has taken the public a long time to gain confidence in electric power and to realize its usefulness. It is only within very recent years that large manufacturers have begun to use electrical power distribution to any extent. At present, the work is being carried on very actively, and highly successful and economical results are being obtained in many large mills. As a means of power distribution, even for short distances, electricity has no rival; while for lighting, its advantages, though great, are relatively much less positive.

Although for many years efficient electric motors have been in general use, there are many central stations in whose business power distribution has not been a very important factor. There are several causes which have tended to restrict the use of electric power, among which we may mention the following: Voltages that have been available for direct current work have not admitted of transmission to considerable distances. Motors have required a certain amount of attention, which users were sometimes unwilling to bestow. In certain classes of manufacture, the sparking of motors has been a source of danger. The most important cause, however, has been that, as a rule, the same apparatus has not been available for the operation of

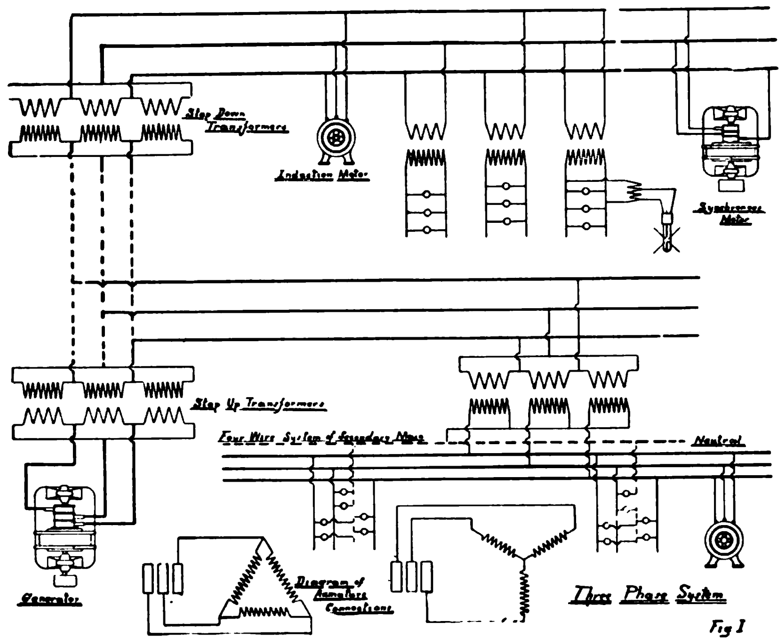

FIG. 1.

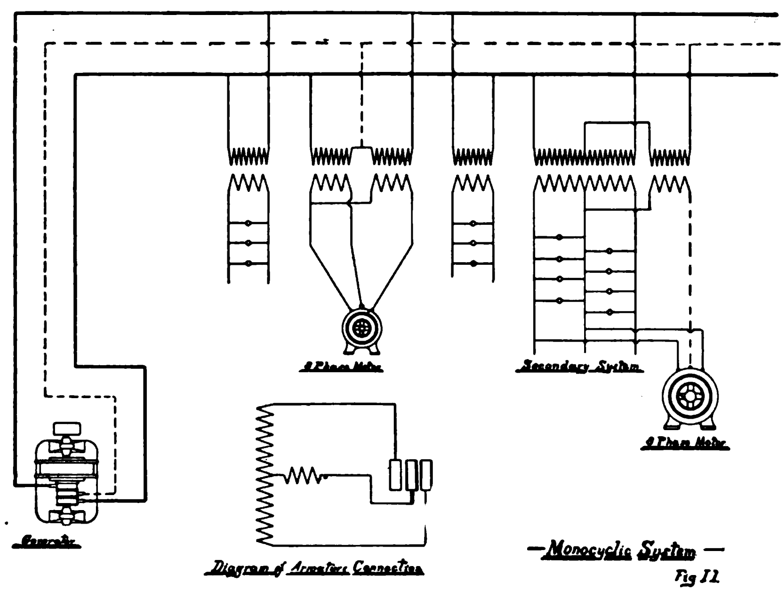

FIG. 2.

lights and motors; consequently, central stations have not been in a position to make attractive offers to large users of power.

With facilities for electric power transmission thus improved, we may look for great developments in the sale of power from central stations. When it is profitable for large manufacturing establishments to put in electric plants for the purpose of distributing power on their own premises, there should certainly be profit in the sale by electric companies of power to large as well as small manufacturers.

The actual saving in fuel effected in the operation of a large mill by electricity for power distribution is ordinarily very large; often as much as fifty per cent. With good equipment, this is, however, only a small part of the saving effected by electrical distribution. The cost of coal seldom amounts to more than half the expense incident to the production of power, and in most cases it is a much smaller proportion of the total. If the power is obtained from a central station, the coal is bought cheaper and used more economically, while the other items of expense will in many cases be almost a clear saving.

The introduction on any large scale of electrical power distribution, of course, requires the investment of a good deal of money in motors and alterations of plant. Power users are often slow to make these investments, because they are not familiar with electrical apparatus and do not realize the advantages to be gained. Repeated investigations have proved that users almost always far underestimate the cost of power. It is the business of the central manager to correct these misconceptions, and to awaken interest in electrical methods. Of course, many companies are working zealously just on these lines. There is no question, however, that there is in many of our large cities a large amount of undeveloped power business. If electrical manufacturers can induce large mill owners to put in plants for electrical power distribution, central stations should be able to sell power to similar concerns.

The following facts concerning sale of alternating power apparatus by one company alone will illustrate the hold which the modern improvements above mentioned have already taken upon the industry of the country:

The first three-phase apparatus made in this country was put in operation two and half years ago. Since then that company has put in operation 33,500 horse-power capacity in three-phase generators; 10,000 horse-power in three-phase induction motors; 14,800 horse-power in monocyclic generators; 6,000 horse-power in three-phase synchronous motors; 10,560 horse-power in rotary converters, and 42,000 horse-power in transformers used for power purposes; the average capacity of the latter being 16 horse-power and the largest having a capacity of 1,100 horse-power.

The production of this apparatus has involved the complete design and development of about thirty new forms of dynamos and thirty-three new forms of motors; each machine so developed involving the construction of new patterns and special tools, which, with drawings, etc., cost in the average about one thousand dollars for each new machine.

The different methods of distributing power and light by alternating currents can best be illustrated by diagrams showing the connections used with each. We briefly review some of the applications of the systems now in general use.

Fig. 1 shows the three-phase system as ordinarily applied to the transmission of power for lighting and other purposes over long distances. The generator may be of any convenient voltage, since step-up transformers are used. These transformers are in three units, or groups, any two of these units being available to transmit a large proportion of the power in case one is disabled. Two sets of step-down transformers are shown, one supplying 1,000-volt distributing lines, and the other supplying a system of four-wire secondary mains. With a given lamp voltage, such mains give a slightly better copper economy than the ordinary three-wire system, and afford an excellent means of secondary distribution.

Such a system as is illustrated in this figure, will give excellent service almost in any town, the low-tension mains taking care of the thickly built up portion and carrying the bulk of the lighting load, while the high tension distributing system covers all outlying portions and operates large power units. A number of large plants have been installed within the last two years, using the three-phase system, as here shown.

Fig. 2 shows the connections for distribution by the monocyclic system. Here all lights are connected single-phase between a single pair of conductors leading from the generator, the motors being operated from the same single-phase circuit in combination with a third conductor leading from what is known as the "teazer coil" on the generator. Here the simple three-wire system is used for secondary distribution, and if it is desired to connect motors to the low-tension mains, a supplementary transformer is used, which supplies a secondary teazer wire; to this and the outside wires of the three-wire system the motors are connected.

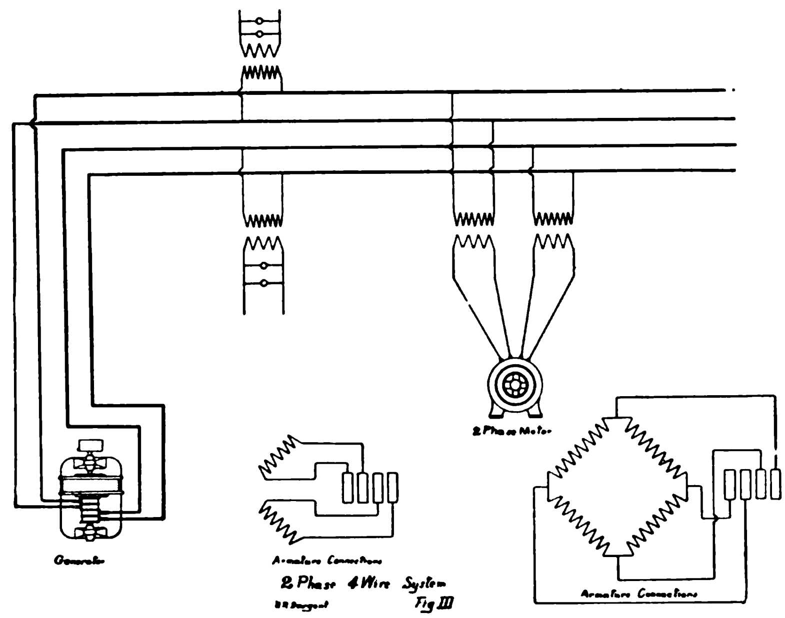

FIG. 3.

The great merits of the monocyclic system are that the number of conductors required for lighting and power distribution is reduced to a minimum, and that no unbalancing is possible. The operation of three-phase motors from this system is in all practical respects the same as when they are run from three-phase circuits.

Fig. 3 shows the connections of the two-phase system, with distribution by four conductors. Here the lighting is divided between two separate circuits, which must be kept balanced within certain limits, depending upon the regulation of the generator, or the amount of care that can be given to the adjustment of pressure on the different sides. Where motors are run, the two circuits must be brought together.

There is no economical and convenient way of operating secondary distribution from this system. Two independent three-wire systems could be operated, but these must be brought together when motors are run. The complication of balancing such a system would be prohibitory.

The two-phase, four-wire system can be operated either from a generator with two independent circuits, or all four conductors can lead from one armature winding. Certain advantages may be claimed for both methods, and both have disadvantages.

Fig. 4 shows a method of single-phase lighting distribution from a two-phase dynamo. Here the two single-phase leads are taken out at points 180 deg. apart on a progressive armature winding. At points ninety deg from those leads two other leads are brought out; each of the latter can be used with the pair of single-phase leads to run one-half the capacity of the machine in two-phase motors. These two power loads can not, however, be brought together.

The greatest disadvantage of this system is that, when carrying a single-phase load, a large proportion of the armature conductors are ineffective, and simply introduce useless resistance and self-induction in the circuit. Thus with the same loss the generator will deliver forty-two per cent. more power as a quarter-phase machine than it will as a single-phase machine.

Fig. 5 illustrates the two-phase, three-wire system, which has been used to some extent both for high tension distribution and for distribution by secondary mains. The principal advantage in this system is that it requires one less conductor than the four-wire, two-phase system. Its disadvantages are that the insulation of the apparatus is subjected to a voltage forty-two per cent. higher than that which is available in transmission, and that the self-induction in the lines and transformers causes an unbalancing of the voltages on the two sides of the system, accompanied by the distortion of the phase variation. The extent of this unbalancing depends upon existing conditions, and is very different in different cases.

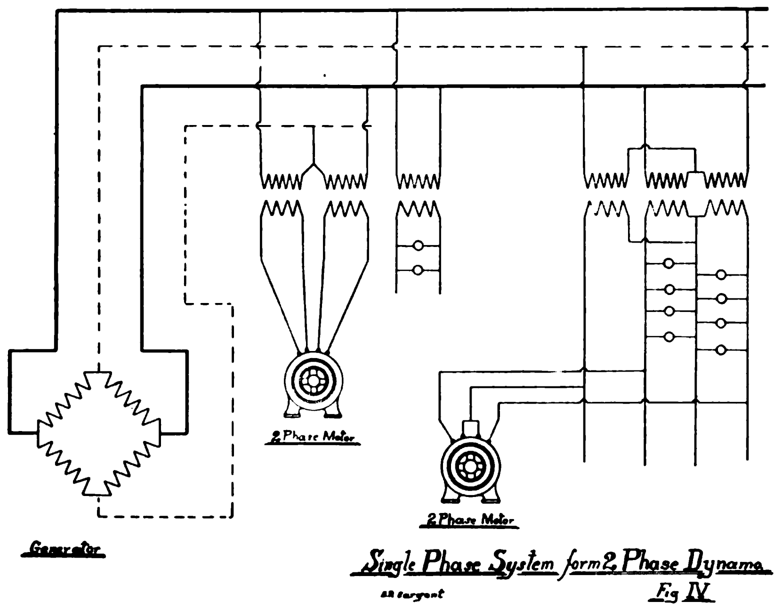

FIG. 4.

In addition to the systems above described for distributing power by induction motors, we have other means of power distribution by alternating currents. The synchronous motor, for certain classes of work, is highly efficient and reliable, and is extensively used, although it will not fill all the requirements of general power distribution. The rotary converter also fills a very important place in the engineering work of the day. A synchronous motor is simply an alternating dynamo whose functions are reversed. They may be used either on single-phase or polyphase circuits. In its simple form, a synchronous motor has no power of starting itself on a single-phase circuit. On a polyphase circuit it starts with more or less torque as an induction motor, and will come to synchronism. As a rule, however, the starting of synchronous motors is not vigorous, and is accomplished by a large draught of current; hence their applications are limited.

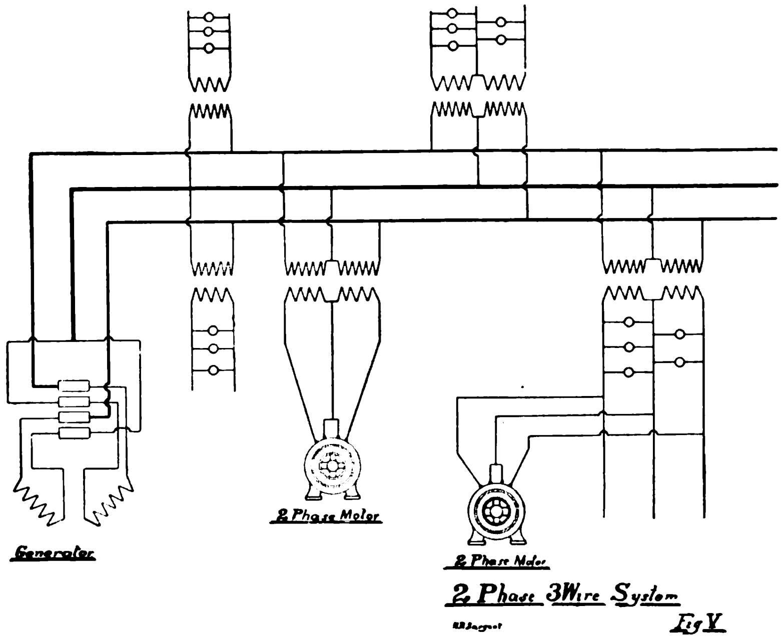

FIG. 5.

A rotary converter is a synchronous motor of suitable construction, whose armature windings, besides being connected to collector rings, are also connected to a commutator. As the machine revolves at synchronous speed, brushes collect direct

current from the commutator, this current being partly rectified and partly generated by the machine. This machine deals in direct and alternating currents and mechanical power; supply it with any one of the three, it will deliver either one or both of the others. It is most efficient when filling its functions as a converter from alternating to direct currents. Its capacity is then greater and its efficiency higher than when it runs as a generator or as a motor.

To illustrate the use of the rotary converter, I will describe an application now under consideration. The company in question is operating three stations; one of these is very large and centrally situated, with condensing water and every facility for the cheap generation of current. Each of the other stations is about two miles from the main stations; both work non-condensing. One of these stations delivers current only on the direct current, three-wire system, while the other, in addition to similar work, carries a considerable arc light load. In this case the following plan is considered:

At the two smaller stations rotary converters would be installed, and would deliver only direct current in one case, while in the other they would also act as motors to operate arc machines through a countershaft, to which they would be belted with clutch pulleys. Suitable step-down transformers would connect the rotary converters to a high tension line leading to the main station. At the same station three-phase generators of large capacity would be installed. These generators would be designed to deliver both three-phase alternating currents to step-up transformers, and also direct currents at about 250 volts to the outside conductors of the three-wire system. They would be directly coupled to engines. These machines would deliver current simultaneously, in any proportion, to the direct current, three-wire system, to the rotary converter, or to lines distributing three-phase power.

It is proposed to operate these machines at a frequency of twenty-five cycles per second, this being well adapted to the direct current work and also to three-phase power distribution.

In this plant an entirely independent control of direct current pressure within a wide range would be necessary at the main and sub-stations. This would be effected without the introduction of idle currents, by the use of a novel form of three-phase induction regulator connected to the alternating leads of each rotary converter. These regulators would give a wide range of adjustment without any moving connections. and would greatly simplify the operation of the plant, and also increase its economy, since the losses introduced by the regulators themselves are very small, and since conditions of general economy are always maintained. Thus a single engine could carry the whole load of the city at certain times.

Another interesting illustration of a combination of alternating and direct currents is found in a case now under consideration. A company controls about 3,000 horse power in water at a distance of eleven miles from a large town. It is proposed to install three-phase, sixty-cycle generators in 600 kilowatt units. The current from these generators will be transformed to 10,000 volts and carried over three wires to a city sub-station centrally placed. Here large step-down transformers will be installed, delivering current to 2,000 volt lines, which extend all over the city and carry motors and lights in outlying parts.

In the same station two large Corliss engines are now in operation, and are belted to clutch pulleys on a countershaft, which operates some arc machines and other load. To this same countershaft it is proposed to couple with a clutch a large synchronous motor which will be connected to the 2,000 volt lines. When the water supply is ample, the engines will be shut down and the motor will run the shaft. When the water is low, or more power is required, the engines will be run and the synchronous motor will then act as a generator, running in parallel with the transmission line.

In the central part of the town it is proposed to install a system of three-wire mains and a large storage battery. This battery would be installed in a second sub-station, conveniently placed. It would be charged from a pair of direct current machines, directly coupled to a synchronous motor operating from the 2,000 volt lines. The direct current machines would be used in connection with the batteries for supplying the three-wire system. The plan here outlined has many positive advantages.

The pressure on the 2,000 volt system can, within certain limits, be controlled at the sub-station by adjustments of the field of the synchronous motor. With telephone communication to the power house, the control will be perfectly easy. The peak of the lighting load being borne by the battery, the generators can be loaded nearly to their full capacity with motors during the day. At night they will charge batteries, using water which would otherwise run to waste.

In both the plants described, the cost of labor would be very small, one man being enough to operate each of the sub-stations mentioned. The saving of labor in operation should be kept constantly in view in all engineering plans. Some of the greatest advantages in modern apparatus lie in its adaptability to such saving.

EVOLUTION OF INTERIOR CONDUITS FROM THE ELECTRICAL STANDPOINT.[1]—I.

BY LUTHER STIERINGER, M. I. E. E.

THE fact that a conference, organized under the auspices of this Association, to secure better electrical construction, was held recently in this city, is in itself an evidence of the importance attaching to the general subject. But the national and influential character of the bodies represented is further proof of the anxiety felt in regard to the matter, and the desire for a higher grade of work. In particular does that feeling concern interior wiring for buildings of all kinds. There is a feeling that the future and prosperity of electricity depend on the methods by which current is introduced into and distributed through modern offices, modern houses, and modern halls. It is felt that, in many respects, electricity has reversed the methods of road-making. In almost every city the roads are fairly good; in most they are excellent. When you strike the country you are likely to find boggy, rocky, uneven tracks and paths, which cause disaster to the buggy and the bicycle. In electrical practice, we have got our main roads in pretty good shape; but when we come to the city line, or, in other words, to the confines of the building, there we begin to strike the wildest and strangest vagaries in the plan and construction of paths for the current that can possibly be conceived. Where the electrical road building, or, as the French say, "canalisation," should be best, it is worst. Let us examine the problem thus disclosed, with the object of finding a plan of improvement. Let us see where the art of interior wiring started, the point it has attained, and the end at which it should be aimed.

Webster defines a conduit as a pipe, canal, channel, or a passage for conveying water or fluid.

According to the standard rules (National Board of Fire Underwriters, 1896), the object of a tube or conduit is to facilitate the insertion or extraction of the conductors, to protect them from mechanical injury, and, as far as possible, from moisture. Tubes or conduits are to be considered merely as raceways, and are not to be relied on for insulation between wire and wire, or between the wire and the ground.

In the development of interior electrical distribution, it is necessary to briefly review the history of the use of the conduit for water, gas, and steam, especially, before the introduction of the powerful electric currents necessary to supply light and power.

GAS FITTING.—In the early gas installations in England, lead pipe was used quite extensively. The work was performed at that time by the plumber. The term "gas fitter" originated and became a special trade in the United States when iron fittings were introduced. Prior to that stage in the art, fittings were improvised by brazing a saddle of brass on a piece of iron pipe. This saddle had a protuberance threaded with a male thread, and after being brazed to the pipe was drilled for a gas way, thus forming an outlet to which a coupling could be attached. The present form of gas fitter's tee is an equivalent of what has just been described. Lead was never employed in the United States for gas piping, except for meter connections and temporary work.

In one of the earliest gas systems in Philadelphia, in 1835, iron mains were run on the outside of the houses, with stop-cocks arranged so that the gas might be turned off before the family retired for the night. This was thought necessary for security, on the supposition that otherwise some unknown cause might develop leaks or trouble. In France, at one period, all gas piping in interiors was left exposed for more ready inspection. The crude methods of installation in that day did not inspire confidence in concealed pipes. Service stop-cocks are still placed near the street curb, as a provision principally against fire, in case the meter or other connections in the interior of the buildings be melted or dislocated and the escaping gas continues to do damage.

On the Continent of Europe there is generally a main tap on the exteriors of premises attached to the service pipe, for the purpose of shutting off the gas when desirable. At the time of the famous Barnum Museum fire on Broadway and Prince street, New York, the inability of the firemen to get at such service cocks, owing to ice-covered débris, permitted the escape of gas inside of the building line to such an extent that the volume of flame rivaled a burning gas well. This continued for several days before it could be controlled.

[1]Read before the N. E. L. A., New York, May 5, 6 and 7, 1896.

Escaping gas is more dangerous than any other medium distributed in a building. Many years of experience have proved that the use of iron piping to convey gas has minimized all possible dangers from leaks or other causes. The early fitting art, by its use of split dies and poor material, was responsible for any lack of confidence as to the ability to confine water or gas to the conduits or pipes.

The reliability of gas, water, and steam conduits in interiors, and the general public confidence in them to-day, can be traced to the creation of the solid die for cutting threads to proper fittings, to superior pipes and to standard threads.

In the United States, prior to 1860, neither water nor gas distributions in buildings, especially in residences, were very extensive. The vitiating effects of gas on the atmosphere of a closed room prevented its use in Europe until a comparatively recent date, except in corridors, assembly rooms, factories and public places. Sleeping apartments are still rarely supplied in England. In this country, however, at the period mentioned, gas was much more extensively used both in residences and elsewhere.

At one period, when cast iron street mains were very expensive, and costly as compared to present prices, several attempts were made to substitute pipes of other material. In a city in the western part of England, an extensive trial was made of transmitting gas through brick conduits and earthenware pipes like the drain pipes of the present day. Pipes of earthenware were used on an extensive scale in some towns in France, the joints of which were made of Roman cement, and the services attached by punching a hole in the main and inserting the end of the leaden service pipe which was secured with cement. This method resulted in complete failure, and several gas companies were all but ruined by resorting to it. The excessive cost of cast iron retarded gas as well as water distribution, enforcing even the use of wood coated with asphaltum as conduits for street mains. During the infancy of street gas distribution, cast iron pipes were made with flanges and put together with bolts and cardboard washers. This practice had to be abandoned and lead joints were at length universally employed. The same method was adopted in water mains. The first street mains for gas, laid in 1807, in Pall Mall street, in London, were of lead. Tinned iron and copper were also used. Paper pipes were in use early in this century for water and gas mains. When used for the latter purpose, they were lined with lead to prevent the hydro-carbon in the bituminized paper from being acted on. Tile pipe as large as twelve inches in diameter was also used.

PLUMBING.—Early plumbing did not comprehend any installation beyond water required for culinary or other special purposes; the introduction of the bath and more lavish use of water only following the more plentiful supply from comprehensive "Central Station" water systems.

It is not many years ago that water had to be drawn from wells and other sources, and carried to receptacles for short storage. Where the luxury of a bath was introduced years ago, it was installed in an outhouse, or an extension to a dwelling or a building, to simplify and reduce the cost of installation. This generally required an extension of the pipes to serve points distant from the street service. For this purpose lead pipe only was used, which caused much annoyance and trouble. The settling of the soft, pliable pipe, if not thoroughly supported, prevented a thorough drainage; and in cold weather the pipes were constantly freezing and bursting. This was the origin of the plumber-millionaire joke.

The use of saws, chisels, and nails, by mechanics in the performance of their work, proved to be a constant source of injury to the pipes, and, as these injuries frequently occurred when the water was turned on, great damage was done to frescoings and furnishings before the source of leakage could be discovered and corrected. Rats and mice would also frequently gnaw into such conduits and cause the escape of the water.

One of the first deviations from the lead pipe practice on an extensive scale was in the latest Western Union Telegraph Building, in New York, on Broadway, in 1870. To avoid the difficulties before mentioned, this building was piped with tinlined brass pipes. From that time on, the practice became general of using in all concealed spaces galvanized iron or brass pipe that could be relied on as safeguard against any of the aforesaid difficulties so that damage might be avoided.

STEAM HEATING.—This is another form of distribution now in general use. It is effected with perfect safety when installed according to modern practices, with metal pipe of sufficient strength to withstand the pressure from within and injury from without.

In the three systems of distribution, which have been outlined as briefly as possible, viz., Gas, Water, and Steam, the following should be noted:

Water produces damage only when allowed to escape, and then only by flooding interiors. Steam is so well harnessed that its escape in a measure does not differ materially in the results developed by water, except that it may cause personal injury through scalding. Gas, however, unharnessed and not properly confined, is capable of twofold destruction: 1st. Its ignition may set fire to surroundings. 2d. Its explosiveness, when pocketed and under suitable conditions. It is also extremely poisonous when escaping and unlit.

It is very rare that dislocation or deterioration in gas piping results harmfully in properly installed systems of gas piping in interiors. The fixtures, of course, are more or less handled, and are liable to derangement, but as they are thoroughly accessible and in full sight, any leaks are easily discovered and corrected.

ELECTRICAL DISTRIBUTION.—In 1881, upon the introduction of the incandescent light, which was designed to supplant gas systems, the promoter's contention, outrunning the inventor's more modest claims, was that the new electrical illumination required the simplest kind of wiring at small cost. The purchaser's objections to duplicating a system of distribution in a building already containing gas piping, induced the promoter to make further statements in the direction of cheapness, which culminated in the claim that the gas pipes already in place could be utilized, and that the electrical conductors could be inserted within them. This was inexplicable to the purchaser, who was told—what at that time became a standing joke—that Mr. Edison had devised an electric bug, and all that was necessary was to attach a wire, insert the bug in the pipe and turn the current on, and it would crawl along and carry the wire with it to any required destination, thus enabling the wire to be placed without difficulty and at little cost. As a matter of fact, Mr. Edison was trying to get the "bugs" out of the system.

With the first installation this question of conductors and their location became one of very serious moment. The method employed was that of a distribution based on a circulation similar to the arteries of the human body, diminishing in size from the source of supply to the points of requirement. Fuses were only applied at the generator, or source of supply, and at the lamp holders, and were designed for this special protection only. Very few intermediates and cut-outs were used, and these were placed in the most inaccessible and unusual positions, and only on one side of the circuits.

Paraffin-covered wire, as employed in prior telegraph and annunciator installations, was adopted for electric light work. This often became heated to such an extent that it frequently set fire to the insulation, and produced burning wires for long stretches between floors and ceilings and under floors. When this came to the notice of the underwriters, they insisted on a non-inflammable wire, commonly known as the "Underwriters" wire, which had a coating of zinc on a cotton fiber braid. This covering, while not being combustible, permitted infiltration of moisture, which caused electroyltic action and the consequent rapid destruction of the wire. Some of the wire gave such bad results in moist places that a twin wire with bituminous covering was substituted. It was known as "Paragon" wire. Much of this for a time gave very good results. The material, however, deteriorated, principally on account of air checks and cracking insulation, and its use had to be discontinued.

About this time various grades of composite and rubber-covered wires of high insulation were introduced with satisfactory results. As in much of the early work done, the wire was supported on cleats and treated practically as if it were bare wire, and as concealed wiring was generally placed in dry structures, defects did not manifest themselves as rapidly as they would otherwise have done.

In the early history of electric lighting, an interior conduit system of wiring was employed. The importance of concealing the conductors in the fixtures necessitated considerable simplicity in wiring to make the same practicable. This was accomplished in the very first commercial fixture, and the general plan then evolved is now in universal use the world over, having completely displaced all attempts to introduce special electric structures.

The attempt of the electrician of that period was to create these special structures just alluded to, based on the lines of his prior practices in telegraphy and other feeble current-carrying arts, introducing contacts, binding posts and other paraphernalia, believing that in this way the whole fixture art would be overturned to make way for the new illuminant. Fixtures, however, are the same to-day as they were before the electric lighting art, except in the modifications of the internal portions so as to admit of inserting or withdrawing the conductors and in the angle at which the light can be directed or suspended.

Internally wired fixtures have been and are placed in all kinds of positions. Where the interior of the tubes has been

exposed to moisture, the inlets have been closed, thereby preventing air circulation and consequent precipitation of moisture. No appreciable deterioration resulted, even where poorer grades of wire were used.

Gas pipe or brass tubing, without any insulation, has been the form of conduit in which conductors were placed in fixtures, the only additional provision in a plain iron pipe that was used being in the case of combination fixtures, where the outside of the iron pipe was taped to prevent chafing of the wires. This was abandoned as soon as the manufacturers recognized the necessity of using properly insulated wire and of so constructing the metal covering of the iron pipe as to prevent chafing. In a paper read before the World's Fair Insurance Congress at the World's Columbian Exposition in 1893, the value of iron conduits was fully recognized, an extract from which is given in the Appendix.

So far as interior electric conduits are concerned, it may be said that they were in use with the first installation, and have been continued, representing the most advanced form of the art, in the large number of fixtures that have been installed. Many of the early plants, such as in mill work, and some of the early expositions have almost as many feet of conductors in the long pipes pendent from the ceilings as there is wiring in the branch circuits.

When it became necessary to conceal wiring, it was common practice to insert moldings (a legacy of the telegraph installations) in floor beams and put the conductors into the grooves provided. There were also many instances at that time of the separation of gas pipe lines and of their utilization for the purpose of inserting conductors, rather than mar the walls or surroundings by external placement. In the fire-room of the steamer "Pilgrim" in 1883, several hundred feet of brass tube were placed without any insulation other than on the conductors. Several other steamships about that time had galvanized iron pipe as conduits without any insulation. It gave good service.

The use of speaking tubes to serve as conduits was quite frequent in early electric light work. A notable installation of this sort was in a large residence at Greenwich, Conn., in 1887. Although the best electrical talent was employed, the mechanical work did not permit of inserting or withdrawing the conductors freely, and they became more or less fixed in position, with the result that the installation had to be overhauled. In fitting up a cottage on the same premises with electric light, small brass-pipe tubing was used. The runs were not long, and the bends, or sweeps, were, therefore, easily placed, and could be concealed without difficulty. Ordinary flexible cords were inserted as conductors, giving satisfactory results. This tube not having been closed at its terminals, permitted circulation of air and developed moisture, which, however, did no harm.

About this time a twin conductor was evolved, based on comparatively no insulation. This twin conductor was patented. The copper conductors were separately covered with a thin cotton covering, without any high insulation. These were laid side by side, and both were covered with additional insulation. The object in closely associating these two conductors in this way was to assure the blowing of a fuse in case of a leak or short circuit. The proximity of the conductors would produce a low resistance arc, the rush of current at that point resulting in the rupture of the fuse. This method was subsequently put into commercial practice, but had to be abandoned, as it developed more faults than the evil it sought to correct, and largely assisted in establishing the use of highly insulated conductors in conduits and raceways in interior installations.

Shortly after the Greenwich installation, a paper tube, impregnated with bituminous compound, was produced. A considerable quantity of this tube was marketed before it was found that, if concealed in plaster or cement, it failed to resist chemical action that ultimately destroyed it. To overcome this, the paper tube was covered with a thin brass sheathing or covering. This, while to some extent resisting chemical action arising from proximity to plaster or cement, was, nevertheless, susceptible to mechanical injury.

During the time that this brass tube was being developed and marketed, the value of an interior conduit system as a means of readily inserting and withdrawing a conductor, was fully recognized by engineers and constructors. A paper was read before the meeting of the National Electric Light Association at Detroit, in September, 1886, entitled "Some Features of Incandescent Lighting and Wiring." In this paper the advantages of a system of distribution and control versus circulation, were fully recognized. Distribution of current in buildings became more systematized through the adoption of a system of distribution and control. (See Appendix.)

The distribution and control system was first brought into comprehensive use in the St. Louis Exposition Building, in 1885, in a permanent plant of over 5,000 lights, in which all the circuits were derived from points of distribution, there being some twenty or more distributing points arranged in the building, with over 400 or 500 local circuits. Had the system thus introduced at that exposition been in general use, as it is now in the best practice conduits would long ago have been extended in the iron, steel or other metal form, from the fixture back to the source of supply, thus filling the gap between the two points, and preventing any disturbance or injury to conductors placed within them.

In the construction of buildings, various artisans must in turn complete their work. The gas piper, the plumber and steam fitter, each has his operations so arranged that he can practically complete the work before the plastering, woodwork and general finish have even been commenced. The use of the conduit likewise permits in branch lines, such as are confined to rooms, the placing of the electrical material in advance of the plasterer or trimmer, if such conduiting be properly arranged between distributing points to which the mains are brought.

At the World's Fair, in 1892, the question came up as to the protection of the conductors, some of which were carrying 2,000 volts alternating current within the buildings. As these conductors in many cases had to be placed under the floors, it became a very important matter to secure them against injury. In considering various methods of protection, all forms of manufactured insulated tubes then on the market, including various kinds of moldings, were rejected, as not affording that freedom from the damage that nails, chisels and other casual or malicious interference might cause. As a result, the Chief of Construction authorized the use of plain iron pipe, relying entirely on the sufficiency of the insulation of the conductors therein placed. The large amount of bare iron pipe so used gave absolutely satisfactory service. The results of this experiment proved conclusively to the various engineers and constructors attached to the electrical work of the Columbian World's Fair the value and sufficiency of the protection afforded by bare iron pipe, since which time they have one and all been firm advocates of its use for conduit purposes.

In 1889, at the retail store of A. T. Stewart, Broadway and Tenth street, New York City, there were installed over 3,000 lamps. All the primary feeders connecting the various converters were placed in gas pipes. The pipes were laid on the iron ledges of the building. Although these pipes and wires of a total length of about two miles were placed by inexperienced men, they were in constant and successful use for over five years, conveying satisfactorily a current of 15 amperes and 1,000 volts, or 200 horse-power, although constantly exposed to the weather. In the subsequent installation of an isolated plant, the above mentioned conductors were again used. In New York and elsewhere, thousands and thousands of feet of plain iron pipe have been in use for many years with high pressure currents operated in them; and there is probably more non-insulated iron pipe in use to-day, much of which was installed many years ago, than in all other forms of insulated conduits so far placed.

To further illustrate the foregoing facts, it may be said that there are about 30,000,000 incandescent lamps in use to-day. Assuming that there are but six inches of pipe to each lamp fixture, we have a total of 15,000,000 feet, or several thousand miles of non-insulated iron or brass pipe in use in fixtures alone; no insulation of the same, other than that furnished with the conductors, having been found necessary.

The best experience of the past 15 years in interior wiring has demonstrated the following facts: 1st. Indiscriminate wiring with staples is universally condemned. 2d. Cleat wiring is admissible in exposed work where the circumstances admit, but not in any concealed work. 3d. Wires imbedded in plaster, depending on the insulation only for protection, are condemned. 4th. Lead-covered wires are also condemned, except where protected in a conduit. 5th. Wires in moldings do not afford mechanical or chemical protection, and are only admissible in surface work. 6th. Wires carried in plaster and covered with split or zinc tubes to prevent injury by trowels, are condemned. 7th. Glass or porcelain insulators can only be utilized in special cases of exposed work. 8th. Paper tubes do not afford absolute mechanical and chemical protection. 9th. Insulated tubes covered with a thin coating of brass or other metals, do not afford absolute mechanical and chemical protection, but, in exposed work, they are, to a certain extent, admissible. 10th. Woven fabric conduit does not afford absolute chemical and mechanical protection. 11th. Heavy insulating covering, integral with the insulation, offers no absolute protection against mechanical and chemical injury, and is analogous to rubber tubing for gas distribution installed throughout a building. 12th. Concentric wiring is practiced in England with satisfactory results, but is not in use in the United States. It offers many possibilities in the direction of

a solid and fixed system. 13th. Paper-lined iron or steel pipes, known as "Iron-Armored Conduit," "Builders' Tube," "Armorite," "Clifton," and plain iron or steel pipe, are the only conduits that can afford absolute security against mechanical and chemical injury and assure permanence.

THE COMMERCIAL VALUE OF ACETYLENE GAS AS AN ILLUMINANT.[1]

BY LOUIS A. FERGUSON.

IT is my intention in presenting this paper to treat of acetylene in its commercial aspect as related to the illuminating industry, and to attempt no description of its value in the chemical world, as the latter is a field entirely apart from that invaded by this Association and one so comprehensive that it might well be made the subject of another discourse.

The first step in the process of manufacture of acetylene gas is the production of calcium carbide, which is accomplished by the reduction of lime by carbon with the intense heat of the arc in an electric furnace. The chemical equation representing the action is $CaO + 3C = CaC_2 + CO$, the CaO representing the lime, 3C the carbon, CaC_2 being the symbol of calcium carbide, and CO carbonic monoxide. Although several experimenters produced carbide of calcium and carbide of sodium and from these acetylene gas many years ago, the first production of carbide of calcium on anything like a commercial scale was made by Mr. T. L. Willson at Spray, North Carolina, while endeavoring to produce the metal calcium in the electric furnace. It was my good fortune to have visited with Mr. Willson his plant at Spray and there carried on experiments in the manufacture of the carbide of calcium and the production therefrom of acetylene gas.

The carbon used in the process at Spray is Pocahontas coke, having a 9 per cent. ash. The coke is conveyed to a hurricane mill, where it is ground to a fine powder and then put with the lime into a revolving mixer by which it is thoroughly mixed and prepared for the electric furnace. Theoretically the proportions of lime and carbon necessary for the production of 100 pounds of calcium carbide are 87½ pounds of lime and 56¼ pounds of carbon. These combine according to the formula before mentioned$CaO + 3C = CoO_2 + CO$, 37½ pounds of carbon combining directly with the metal calcium forming calcium carbide, and 18¾ pounds combine with the oxygen of the lime, forming carbon monoxide gas which passes off from the furnace.

Nearly twelve months ago, on May 15, 1895, at Spray, N. C., the writer, together with Mr. George O. Knapp, of Chicago, Mr. T. L. Willson, and Major Morehead, of Spray, N. C., carried on a test to show the actual production of calcium carbide per horse-power per day and the volume of acetylene obtainable per pound of carbide. The coke and lime were prepared in the manner described, the mixture containing 800 pounds of air slaked lime and 390 pounds of powdered coke, making the total weight of mixture 1,190 pounds. Of this mixture 180 pounds were unused, leaving 1,010 pounds, which were delivered to the furnace. The test run was for a period of three hours, during which the mixture was fed into the furnace by shovel, as required, and the material stocked regularly. The current used varied from 900 amperes to 1,200 amperes as extreme limits, but being kept very regularly at about 1,000 amperes, the voltage varying from 90 to 104 at the extreme and being kept fairly constant at 100 volts. Readings were taken approximately every ten minutes during the test and from twenty-three readings the average showed 1,000 amperes and 100 volts, or an average consumption of energy at the terminals of the furnace of 100 kilowatts during the entire run of three hours.

After the current is turned on and the arc made, the carbide begins to form on the bottom of the furnace under the upper carbons in the shape of a block, and as it forms it is necessary to raise the upper carbons to maintain the proper arc, the current passing from the carbons in the form of the arc to the carbide below, the latter now constituting the other pole of the arc and conducting the current to the plate in the bottom of the furnace. The production of the calcium carbide is by the heat of the electric arc alone and not by electrolysis, the temperature of the arc being in the neighborhood of 3,500 deg. to 4,000 deg. C., while that of the ordinary smelting furnaces ranges from 1,200 deg. to 1,500 deg.

At the end of the run the current was cut off, the furnace was allowed to cool down and the product and unused material removed and carefully weighed. During the production of the carbide some of the mixture is lost by passing up the chimney with the gases of reduction, which burn with wild sheets of flame, increasing with their hissing the already deafening roar of the immense alternating current arc. The weight of the calcium carbide actually produced in this test was 139 pounds, the unused material amounting to 607 pounds, to which must be added the water contained in the lime, 165 pounds, making the total unused material 772 pounds. The weight of the mixture delivered to the furnace was, as stated before, 1,010 pounds, so that the actual weight of mixture consumed and lost in the process of manufacture of 139 pounds of calcium carbide was 238 pounds. The efficiency of production therefore would be the weight of carbide produced divided by the weight of mixture used up, or 139 divided by 238, which gives 58.4 per cent. as the efficiency of production.

The next step is to calculate from the results of the tests the amount of carbide produced per kilowatt hour. We have seen that the average value of the energy expended in the production of the carbide was 100 kilowatts and that we produced 139 pounds of carbide in three hours, or at the rate of 46⅓ pounds divided by 100, which is $^{46}/_{100}$ pound, or at the rate of 11.12 pounds of carbide per kilowatt per 24 hour day, or 8.3 pounds per horse-power per day of 24 hours. A sample of this carbide produced, weighing 34.1 grammes, was then taken and the acetylene gas formed by adding water, and the gas evolved, measured by means of special apparatus, showed a result of 5.24 cubic feet of acetylene gas per pound of carbide after making the proper temperature and barometric corrections.

Having thus seen the quantity of calcium carbide produced for each kilowatt hour of energy consumed, and the value of the carbide as a producer of acetylene, we will now take up the method of production of acetylene from the carbide and consider some of its properties before determining the cost of production of the carbide.

Acetylene is produced from the calcium carbide merely by the application of water, the action being shown by the equation: $CaC_2 + 2H_2O = CaOH_2 + C_2H_2$. When the carbide is thus brought in contact with the water the acetylene gas is given off rapidly and its presence is distinguished by its very pungent odor somewhat resembling phosphorus. When lighted, it burns with a deep yellow flame and is extremely sooty, but when generated at an even pressure, and burned with proper burners designed for the use of acetylene, it gives a beautiful white light. The acetylene flame so used is exceedingly tenacious and it is almost impossible to blow it out, which may be considered as an advantage in hotels and other places where rural gentlemen occasionally take up their abode.

A simple method of generating acetylene from the carbide is to use the apparatus described in brief, as follows: Take an ordinary chlorine generator and place within some lumps of the carbide, arrange a glass funnel so that water may be admitted to the interior of the generator, connect the generator by means of a rubber tube to a gasometer, the outer tank being partially filled with water; from the gasometer above the water line another tube connects to a gas pipe with a set of burners attached. Water is then poured gradually in small quantities through the funnel into the generator and upon the carbide. The acetylene gas thus generated passes through the tube to the inside of the gasometer and lifts the gasholder, the position of the latter changing with the quantity of gas generated. The gas is then delivered from the holder by means of the rubber tube to the piping and burners. As the gas is consumed the holder lowers and a fresh supply is generated by admitting more water through the funnel upon the carbide in the generator.

Another method, which is automatic in its action, is to partially submerge a vessel in water, the vessel being open at the bottom and containing the carbide suspended on a screen in the upper part of the vessel. The gas is then drawn from above the carbide, and as long as it is being used, the water remains more or less in contact with the carbide; but as soon as the consumption of gas ceases or diminishes, the pressure of the gas forces the water downward into the lower part of the vessel and away from the carbide, thus causing the generation of the gas to cease. An arrangement similar to this is one proposed for country residences.

Acetylene gas may also be used in its liquid form and is prepared by decomposing the calcium carbide with water in a closed vessel and conducting the generated gas under pressure to a condenser where it liquefies and is then drawn off in tanks for shipment and distribution.

Compared with other gases acetylene has a very high candle-power. Water gas, which is used in nearly all the large cities of the United States for illuminating gas, when burned at the rate of five cubic feet per hour gives from 20 to 25 candle-power, while acetylene when burned at the rate of five cubic feet per hour gives, according to most observers, 240 candle-power, or approximately ten times the illumination of water gas.

---

[1]Read before the N. E. L. A., New York, May 5, 6 and 7, 1896. Abstract.

The temperature of the acetylene flame is low as compared with that of water and coal gas, Prof. Lewes placing the temperature of the acetylene flame at 1,000 deg. C. and the coal gas flame at 1,360 deg. C. It has been stated by Prof. Crafts, of the Massachusetts Institute of Technology, that the true relation of the temperature of the present commercial illuminants when giving the same candle-power is: Incandescent light, 1; acetylene, 3; and the water gas, 9; showing that the incandescent lamp gives off the least amount of heat per candle-power, while acetylene gives three times that of the incandescent lamp and one-third that of water gas.

Many experiments have been made by noted scientists and investigators to determine the poisonous qualities of acetylene gas. Guinea-pigs, dogs and other small animals have been made martyrs to science and subjected to mixtures containing carbonic oxide, which is the poisonous constituent of ordinary illuminating gas, and after their death their blood has been examined and the amount of carbonic oxide absorbed by the blood determined. Grehant made comparisons of carbonic oxide and acetylene, to determine their relative poisonous qualities, upon dogs. In his experiments he used 20 per cent. of oxygen in mixtures, so as to prevent the animal's death by suffocation. He added enough Paris illuminating gas, which contains 7 per cent. carbonic oxide, so as to give 1 per cent. carbonic oxide in the mixture. The dog showed signs of suffering after three minutes and in ten minutes the dog was very sick, and his blood showed 27 volumes in 100 of carbonic oxide. Another dog was subjected to a mixture containing 20 per cent. oxygen and 20 per cent. acetylene, and the dog breathed without inconvenience for 35 minutes. Upon examination his blood showed 10 per cent. acetylene, less than 1/2, the rate of absorption of carbonic oxide. The mixture contained much more acetylene than that to which a person could be subjected in the use of acetylene as an illuminant, since a leak of the gas would produce an explosion in the room of a dwelling house before the percentage of acetylene mentioned were attained in the atmosphere. Similar experiments were carried on by Brociner, Berthelot, and Claude Bernard, and the conclusion of the best authorities indicate that acetylene when pure is not poisonous. Berthelot has pointed out that the old method of preparation of acetylene by means of acetylide of copper may contaminate the gas with hydrocyanic acid, and thus render it poisonous.

Having seen how the calcium carbide and acetylene are made and having considered their properties, the question now before us is the cost of producing them. The results of the tests made at Spray, and before described, show that 8.3 pounds of carbide is produced by each electrical horse-power in one day, or .433 pounds per kilowatt hour; also that the efficiency of production was 58.4 per cent. Experience at Spray shows that the carbons used as electrodes last about seventy hours with the same amount of energy as used in this test. The cost of these carbons is $2 each, which approximates six cents per pound, or 18 cents per kilowatt hour. The cost of lime I have put at $5 per ton and coke at $2.50 per ton, these figures being about the average prices for these materials of good quality, and considerably less than the actual cost of them at Spray. The question of the cost of electrical energy is the all important one, so that I have taken the Niagara price of $20 per electrical horse-power per year of 8,760 hours, considering this to be the lowest commercial price obtainable at the present time, and one which offers no question as to its accuracy, it being one which is absolutely tangible. The estimate is further based on the assumption that the carbide plant is to be operated at full load 24 hours per day and 365 days each year, so that the actual cost per electrical horse-power hour of energy consumed may not exceed $20 divided by 8,760, which is .238 cent, or .317 cent per kilowatt hour. With this data as a basis the cost of producing one ton of calcium carbide at Niagara Falls, in a plant having ten 200 kilowatt furnaces producing ten tons of carbide per day, would be as above.

The estimate of cost per ton of calcium carbide is intended to represent the cost of manufacture to a large gas company operating in New York, Boston, Philadelphia or Chicago with its calcium carbide works at Niagara, and whose business would be to produce acetylene from the carbide in the city where the gas is to be used and to distribute it to its customers through its existing mains. It is not intended to represent the cost cleared off its books of any corporation or firm whose sole business would be the manufacture of calcium carbide for the market, for to cover that case we must add to the above estimate the cost of general expense, including administration, royalties, and selling expenses which of necessity would be equal to a large percentage of the factory cost as given.

Let us then consider the value of acetylene to the gas companies in large cities. In many articles and circulars treating of this question, it has been customary to place the actual cost of acetylene as produced from the carbide, taking the factory cost of the carbide as a basis, against the selling price of illuminating gas at $1 per 1,000 cubic feet. This, of course, is not a fair comparison and is very misleading. Believing that the only fair way to consider the relative value of acetylene and water gas is to compare them upon the basis of cost per candle-power hour in the holder, and assuming that the cost of distribution is the same in each case, I will treat the question on that basis.

We have seen from the results of the tests at Spray that for each pound of carbide we obtained 5.24 cubic feet of acetylene, or 10,500 cubic feet per ton; therefore, the cost per 1,000 cubic feet of acetylene would be one-tenth the cost of one ton of calcium carbide. The candle-power of acetylene being placed at 240 for each 5 cubic feet of gas, and the candle-power of water gas in the large cities at 25 for each 5 cubic feet of gas, it will be seen that the candle-power of acetylene is ten times that of water gas per 1,000 cubic feet, and, therefore, the cost of acetylene giving the same candle-power as water gas would be equivalent to water gas at a cost per 1,000 cubic feet equal to one hundred of the cost per ton of the calcium carbide. For example, if the calcium carbide costs the gas company $100 per ton then the cost of acetylene gas in the holder will be equivalent to 25 candle-power water gas costing $1 per 1,000 in the holder.

The present average cost of illuminating gas in the holders of the large gas companies approximates 30 cents per 1,000 cubic feet, while the cost of acetylene gas in the holder with calcium carbide at $37.69 per ton would be equivalent light for light to illuminating gas at 37 7/10 cents per 1,000 cubic feet, making the cost per candle-power hour of pure acetylene approximately 20 per cent. higher than that of ordinary illuminating gas. If acetylene were mixed with air and distributed, the cost would be less. This has been done in an experimental way, using 60 per cent acetylene, and 40 per cent. air, but the advisability of attempting to distribute such a mixture through a system of mains in a city for commercial use is exceedingly questionable, owing to the risk of the mixing being improperly done and the quantity of acetylene falling to such a percentage as to form an explosive mixture.

It has been suggested that the cost of distribution, as well as the cost of mains and maintenance, which constitute a large portion of the cost in the lighting industry, might be saved by the use of liquid acetylene, put up in cylinders and delivered to the stores, and residences, and offices so that the consumer might generate his own gas as required. It appears to the writer that this method is an entirely impracticable and uncommercial one, as there are almost insurmountable objections to be overcome. Neither the average business man nor the

occupants of a residence wish to be bothered with the care necessarily attendant upon the use of the cylinder of acetylene. It would be necessary either to have two cylinders ready for service or to have a second one placed in service before the first one were exhausted, and in all probability the busy man would find himself in darkness at the time when he most needed the light, owing to the fact that he had neglected to renew his cylinder. The pressure of the gas in these cylinders is from 600 to 700 pounds, so that it is necessary to use a reducing valve which will give a presssure of one ounce. The same valve which is used with the Pintsch system of railway lighting is employed, but this in all probability would not be kept in condition by the ordinary householder or storekeeper, and the consequence would be that the full pressure might be impressed upon the pipes, and in case this were prevented by the use of an auxiliary safety valve, then every failure of the reducing valve would allow all the gas to escape and be lost. The use of acetylene cylinders would increase the danger in case of fire, since the gas would escape should the cylinders become heated and explosions of the mixture of acetylene gas and air would possibly follow. After considering the many inconveniences and dangers in the use of liquid acetylene in the business and residence district of the large cities, it leads the writer to believe that acetylene to be commercially successful must be delivered to the customers in the form of gas through a system of mains, as is done now with ordinary illuminating gas. Liquid acetylene should find a field in the lighting of country estates, railway trains, and for use in carriage, bicycle, and locomotive head lamps, and in isolated places where distribution by mains is not possible.

When acetylene was first brought forward to be used commercially, it was expected that the gas companies might still maintain their existing gas works and use acetylene to enrich their gas and furnish a 25 candle-power flame as formerly, but at a much less cost. Experiments have shown, however, that although coal gas may be enriched by acetylene, water gas is not susceptible to enrichment by it. Water gas, which is furnished in nearly all the large cities, has little illuminating power of its own, is now treated with petroleum, and it is only when enriched to a certain candle-power that acetylene may be mixed with it without losing its candle-power, so that we cannot, as at first supposed, substitute acetylene for petroleum and use it economically as an enricher of low candle-power water gas.

It has been suggested that the manufacture of calcium carbide might be carried on by central station electric lighting companies as a by-product, furnishing the energy necessary for its production during hours of light load upon the lighting system, thus bringing the load curve of the station nearer to a straight line and thereby improving the economy of the station operation. It will be readily seen from the figures given in the estimate of the cost of producing the carbide, that the cost of power is a very important factor, and if we increase the cost given, of $20 per horse-power per year, we will correspondingly increase the cost of the carbide. From experience with the cost of operation of the largest central lighting stations in this country, the writer can safely state that the absolute cost of fuel alone in the most economically operated lighting station of the most modern type of multiple expansion condensing plant averages .3 of one cent per kilowatt hour, or approximately $20 per horse-power per year continuous service, while the total cost of generation in the station would average over double that amount.

In the average of the large central stations the generating cost at the switchboard, without distribution and general expenses, approximates one cent per kilowatt hour, which is about $65 per horse-power per year, and in the smaller stations using steam, double that amount. It is obvious then that we may not hope to use our present central stations during minimum hours for the manufacture of calcium carbide as a by-product while the cost of power in our stations remains as it is at present, and the amount of power required for the production of carbide is so excessive that the cost of its production by the central station would be prohibitive. It would be much better and more economical for the central station manager to sell his electrical energy through the incandescent or arc lamp at the same price per kilowatt hour than to use the energy for the production of carbide, since the cost per candle-power hour would be less when the electrical energy is converted into light directly through the incandescent and arc lamps than through calcium carbide and pure acetylene, assuming the cost of distribution and general expense to be the same in each case.

Take, for example, carbide at $40 per ton, which means 40 cents cost per 5,000 candle-power hours of acetylene gas in the holder, or 125 candle-power hours for one cent. Compare this with electrical energy at the switchboard at two cents per kilowatt hour. For each kilowatt hour generated we obtain twenty 50 watt incandescent lamps, each giving 16 candle-power, making a total of 320 candle-power hours per kilowatt hour, or 160 candle-power hours for one cent, which is 28 per cent. more candle-power for the same expenditure of money by the use of the incandescent lamp directly as a converter of electrical energy into light as against the conversion by means of carbide of calcium and acetylene.

If we take the case of the arc lamp and add to the cost of the electrical energy 1.5 cent per kilowatt hour for carbons, trimming and lamp repairs, making the total cost 3.5 cents per kilowatt hour, we find it still more advantageous. Assuming a 500 watt arc lamp gives 1,000 candle-power, we have 2,000 candle-power hours per kilowatt hour, or 575 candle-power hours for one cent, which is 4.6 times the illumination for the same money as compared with pure acetylene gas.

Taking the cost per kilowatt hour at the switchboard in the large central stations, we obtain 320 candle-power hours for one cent, which is 156 per cent. more candle-power for the same expenditure of money by the use of the incandescent lamp directly as a converter of electrical energy into light as against the conversion by means of carbide of calcium and acetylene.

By means of the arc lamp on the basis of cost of one cent per kilowatt hour for electrical energy and 1.5 cents per kilowatt hour for carbons, trimmings and lamp repairs, we obtain 800 candle-power hours for one cent, or 6.4 times the illumination for the same money as compared with pure acetylene gas.

From these deductions and considerations, it may be concluded in the light of our present knowledge and upon the basis of the estimated cost of production of the calcium carbide, acetylene gas should not drive the incandescent and arc lamp from the lighting field; neither should it make such inroads on the electric lighting business as to materially affect the earnings of existing central station companies, for after all, acetylene is a gas and burns with a naked flame, and the use of incandescent and arc lamps has steadily increased year by year, not because of their cheapness, but because of their infinite superiority as illuminants over any gas flame yet developed.

SINGLE-PHASE SELF-STARTING SYNCHRONOUS MOTORS.[1]

BY F. H. LEONARD, JR.

EVERY central station manager who operates an alternating plant has to grapple with the question of power distribution. Applications for power service come in from every direction, and in many cases, properly worked up, would make a more remunerative business than that of furnishing current for lighting purposes. It is, perhaps, unnecessary to point out that the bulk of the lighting service averages but a few hours per day, whereas the motor service covers a much longer period with a corresponding reduction in cost of the current output. The difference is so great that many stations are furnishing current for motor service at 50 per cent. of the price for lighting service, and, even then, figure that the motor business is the more profitable.

The drawback to the single-phase synchronous motor has heretofore been that it could not be started without some other source of power, and would not carry its load up to speed. Motors are now made in which this is entirely overcome. They start up under load, and can be specially wound to give much greater torque in starting than when running in synchronism.

Two simple, well known principles are combined in this motor: The principle of the ordinary alternating current synchronous motor with that of the direct current motor or generator. The armature has two distinct windings; one, a distributed winding connected to a commutator, similar to that of a direct current motor or dynamo, which in this motor is used for starting and afterwards for exciting the field. The other winding is of the shuttle type, wound so as to concentrate distinct and regularly alternating poles in the armature, and performs the regular work of rotating the motor armature, advancing it from one pole to the next, with each impulse of the generator.

An ordinary double-throw switch on top of the motor is used in starting, there being no resistance or other complicated device, as the self-induction of the windings is sufficient to choke back any abnormal flow of current. In starting, the switch-handle is depressed so that the lead wires which conduct the alternating current from the transformers are connected through the switch blades to the contacts which lead the current first to one of the commutator brushes, thence through the

[1]Read before the N. E. L. A., New York, May 5, 6 and 7. Abstract.

distributed armature windings and out through the opposite brushes to a coarse wire winding on the field poles and back again to the switch contacts and binding posts, these connections being identical with those of a direct current series motor. As soon as the current is turned on, the motor commences to rotate at a constantly accelerating speed until synchronism is reached, which is indicated by the lighting of a lamp located on the switch at a dull red. This is the signal for the reversal of the double-throw switch, which then changes the complexion so that the leads from the transformer are cut off from the commutator and connected to the collector rings and concentrated armature windings, while at the same instant the commutator brushes are connected to the shunt field windings, magnetizing the field with direct current, the only office of the commutator after the motor is started and up to speed being to supply the small direct current necessary to magnetize the field.

In starting without load, the motors will run up to synchronous speed in from five to fifteen seconds, depending upon size, windings, etc., and when loaded in from fifteen to thirty seconds, taking about the same current in either case, the time factor making the difference in the power consumed; the current taken under these conditions amounting to from 25 to 50 per cent. in excess of what the motor will require when running in synchronism. But when only required to start itself or light counter shafting, this current may be greatly reduced by special windings.

The direct current winding delivers a perfectly smooth current, and is not at all pulsating in character. In circuit with the field winding is a rheostat to control the extent of field excitation. This rheostat is located in a recess in the base of the motor, the handle for its regulation being accessible through the oval opening at the commutator end pedestal. The motor, starting switch and field rheostat are in one piece, making a most simple and compact combination. All that is necessary to install the motor is to connect the secondary wiring of the transformer to two binding posts on the motor, and it is ready for operation.

The field crown is of the multipolar type, with field cores pointing inwardly; the magnetic circuit is composed of sectional sheet iron punchings, each section including two poles, stacked so as to break joints. These punchings interlock and are clamped between two cast iron rings with bolts passing through from side to side, which serve to clamp the whole together solidly, at the same time holding each punching in its proper place and tying them like links in an endless chain. The bottoms of the cast iron rings are milled to fit the base of the motor, to which they are firmly bolted.

On top of the field crown is placed a starting switch, and all the electrical connections from fields, commutator and collector brushes are brought around the outside of the field punchings to the top, concealed from view, however, by the perforated steel jacket, which is held in place by grooves in the cast iron clamping rings, forming an ornamental finish and greatly increasing the radiating surface.

As this motor runs at a constant speed, it has been necessary to devise several arrangements to accomplish what might be done by variable speed motor. Motors are made for blowing church organs, in connection with which it has usually been customary to provide complicated automatic speed regulating devices. With this motor no attempt has been made to vary the speed. The organist closes his circuit and starts his motor by means of a pedal. A blower, driven by the motor, fills the bellows and maintains a constant pressure, usually about four ounces per square inch. If no air is used, the blower spills the wind out of its fan and requires only enough power to overcome the friction and maintain the pressure. As fast as the air is used the blower takes a corresponding amount of power, the motor absorbing the current accordingly.

An arrangement for elevator service which is extremely simple has been devised. The constant speed alternating motor, cable drum and gearing are all mounted on a single base casting, in which the respective parts are bolted. There is a pinion on the shaft of the motor which engages two bevel gears, each mounted on a sleeve, which also carries one part of a friction clutch, the two sleeves rotating in opposite directions, and the whole being supported by and turning freely on the worm shaft which engages the worm-wheel that turns the cable drum. The other part of each clutch is keyed to the worm shaft. The controller wheel is mounted on an extension which is cast on the case that entirely incloses the bevel gears and pinion, permitting them to run constantly in oil. This controller wheel is connected to the controller cables or hand ropes which serve to operate the elevator. A pull on the hand rope turns the controller wheel, rotating it through an arc of 60 deg. This rotation serves, first, to release the brake on the worm shaft, by means of the adjustable link and lever, by depressing the roller which travels over the cam in the controller wheel; at the same time, one shipper fork is moved by the connecting rod at its upper end, which is pivoted near the upper rim of the controller wheel, far enough to cause one of its clutches to engage its other part on the sleeve attachment to the bevel gear, so as to drive the worm shaft and rotate the cable drum. At the same time, the connecting rod attachment to the shipper fork opposite moves across the center of the controller wheel without producing more than enough movement to take up the lost motion in the clutch parts to which it is attached. Pulling the hand rope in the opposite direction brings the parts back to their original position, disengages the clutch, and sets the brake on the worm shaft. Pulling still further in this direction, the opposite connecting rod travels so as to move the shipper forks and engage its clutch, turning the hoisting drum in the opposite direction, while the first mentioned connecting rod moves across the center without causing any appreciable movement of the shipper fork. The motor runs continuously in one direction during working hours, and there is no heavy rush of current in starting as with a direct current series motor, with its tendency to drop the brilliancy of the incandescent lights on the same circuit.

These motors are suited to any frequency in general use in this country, and are wound for from 140 to 60 complete periods per second, the speed being fixed by the frequency of the generator or circuit to which it is connected.

While this motor was designed for single-phase circuits, yet it is obvious that it will work quite as satisfactorily when connected to either leg of a two or three-phase circuit, and where such circuits are loaded with induction motors, a few synchronous motors properly distributed and somewhat over-excited would serve to allay the pernicious effects of the inherent lag or idle current which goes with induction motors, at the same time raising the e. m. f. at the extremities of the line, reducing the drop in the conductors and allowing the generators to do more work, inasmuch they would not be required to deliver so large a wattless current.

This synchronous motor is also a good rotary transformer, and lends itself very conveniently for charging storage batteries and electrolytic work, the alternating current entering at collector rings, while direct currents are delivered from the commutator brushes. For laboratory work and as a piece of apparatus in colleges that teach electric engineering it is invaluable; for, besides the previously mentioned uses, it may be driven by direct currents as a series motor; further, it may be run at a constant speed as a direct current shunt motor, while from the collector rings alternating currents may be taken at any frequency, dependent upon the speed, which can be regulated by resistance in the field or armature circuits; or belt driven, it may be used as a self-inciting alternator.

THE EVOLUTION OF THE ARC LAMP.[1]

BY L. H. ROGERS.

THE author first drew a rapid sketch of the early history of the arc light, beginning with the discovery of Sir Humphry Davy, tracing the successive steps of inventors to make arc lamps which would operate independently of one another when connected to the same machines, and the failures that were encountered down to the time of Brush, in 1875. He drew attention also to the fact that the lamp had not kept pace with the dynamo in the march of progress; and continued, as follows:

The Arc Lamp Must Meet the Demand.—Remember that the title of this paper is "The Evolution of the Arc Lamp," and that evolution denotes a continuous development. Since Brush perfected the fundamental principles of the commercial arc lamp, what has been done? In 1875 the arc lamp was a great ball of wonderment. In 1878 to 1880, a few were induced to really try them practically. During the next decade, the mad lighting fever was in full sway, and 250,000 arc lamps had been hung up in the United States by 1890. The manufacturing companies were too busy shipping and collecting to thing of anything but of something which would burn. The lighting companies were too busy making contracts with municipalities and supplying the demand for light to ever look to see what was inside the lamp.

But this is the age of close inspection. Municipalities are not paying $350 per year for a 2,000 candle-power arc lamp in 1896. They encourage other companies entering their city limits, and this brings keen and active competition. If competition is not encouraged, or if prices for lighting are not reduced, the taxpayer—that tireless individual who never dies—is heard from, and starts the agitation for a municipal plant on the theory of his new discovery that electricity costs nothing to "make."

[1]Read before the N. E. L. A., New York, May 5-7. Abstract.

It is not the purpose here to discuss this swing of the pendulum from too high prices—it has, indeed, swung too far already in the other direction—but it does behoove us to examine closely into the daily expenses and annoyances to which the electric lighting plant is subjected.

There is no business which has developed so rapidly and so radically as that of electric lighting. The frame building, 20 feet square, has been replaced by a handsome brick and iron-roofed structure, 150 x 300 feet, and three stories high. The deliberate saw mill engine, at 90 revolutions, has been replaced, first by the diminutive busy little high-speed engine at 350 revolutions, then by a larger type of the slow speed engine, and later by a compound condensing engine at a piston speed of 800 feet per minute. The transmitting devices have been changed from belt to rope, and rope to direct. The boilers have undergone a radical change, and the manufacturer must now guarantee the pounds of water evaporated per pound of coal by his make. Remarkable and needed improvements have been made in the dynamo, as we have mentioned. The efficiency has been raised from 50 to 85 or 90 per cent. A 125-light machine is less trouble and care to run than an old 10-lighter.

In all this development; this search for high efficiencies; in this attempt to get running expenses down to the minimum, the arc lamp has been overlooked. The most important single piece of mechanism in the entire system, it has been the last to receive serious attention.

There are 2,711 central lighting stations in the United States, with $320,000,000 invested. The sole and only object of this outlay is to get light. The engines, dynamos, belting, conduits, buildings, are all secondary to the arc lamp. It is the exponent of the entire problem. It is literally in the "eye of the public" day and night. Its lines of—I was about to say beauty, but who ever heard of a beautiful arc lamp? At any rate it stands against the morning sky, or the evening sunset, and in truth, I hear the public say, "It must be the best the electricians can do, for I have watched for fifteen years, but have seen no change; they are all alike in their hideousness."

And now, let us look at the subject squarely. Let us hold the arc lamp up between the fluorescent screen and the Crookes tube, and in the light of X-ray, '96 knowledge, examine the arc lamp hanging in our streets.

We find a device 50 to 60 inches long, made of long tubes, or chimneys, a sheet iron drum, long side rods, and at the bottom a globe-holder. We can see Davy's two pieces of charcoal—one is 12 inches long, and the other six, the rate of consumption has not changed. We realize that the useful length of this lamp is the vertical length of the carbons. Dividing 18 inches by 50 inches we find that the useful length of this device is only 36 per cent. of its total length. The statement may be made by some enthusiastic observer that there are two pairs of carbons, one pair alongside the other, but he must not forget that with our improved eyesight in '96, we can look clear through the device, and see not only the skeleton, but the marrow in the bones.

These carbons are fastened firmly in their respective holders, and the holders are rigid. The burning of the arc causes the carbons to point up quite decidedly. When the current is shut off momentarily, these points fall together, and it very often happens slip by each other and wedge. When the current is again sent through the coil, its lifting power is not sufficient to pull the carbons apart, the lamp is rendered utterly useless—the policeman reports it out, and a deduction is made from the bill of the lighting company to the city. To prevent these deductions, amounting to more than the original bill, a corps of patrolmen are engaged, whose business it is to watch the lamps all night long, to prevent them going out, as a nurse would watch a sick child.

We find the interior of the device full of springs—some of them with ratchets and cog wheels, some with six magnets or coils, all with three or more; springs without number, and of every size, regulating devices, auxiliary levers, light and flimsy pieces of every shape and size, the device for gripping the rod in most cases an annular ring gripping the carbon rod by tilting so that its knife edge holds on the side of the rod, the current being conducted to the carbon rod by means of a sliding contact, delicate brushes against which the carbon rod rubs as it feeds the carbons downwards, cut-out spools which have little shows of their own with independent armatures, and additional coils of wire, carbon rods sticking away up into the dark recesses of the chimneys, rods which must be carefully housed and carefully cleaned with crocus cloth each day. We notice also that for three or four inches above the casing the rod cannot be cleaned by the trimmer; it therefore becomes spotted; a bit of weather or a bit of dust changes the nature of the brass, and the current carrying brush when it reaches this spot does not make a good connection, a little blister is formed, which in turn blisters the surface of the brush, and this in turn blisters the rod the entire length until crocus cloth is powerless to smooth it. The lamp then must come in, for in the mean time many other little things have happened, and nothing but a thorough overhauling will put the lamp in good condition again.

It would require a volume to recount the details of the troubles that are occurring every hour, in every lighting plant on the face of the globe. You, who are within reach of my voice, know too well that your arc lamps give you more trouble than all the rest of your apparatus combined. These troubles have come upon you so gradually, however, that you have become accustomed to them. It seems that some station men actually delight in keeping a force of men repairing old lamps, and a horse and wagon busy hauling them in and taking them out again.

Alexander Dow, electrician for the city of Detroit, connects four 100-light dynamos to one engine, for the reason, as he states, that the ratio of troubles is 4 to 1. I wonder how many dynamos would be connected to each arc lamp, or arc lamps to dynamos, provided the number were dependent on the ratio of troubles?

And now, we have reached the year 1896; we have given the arc lamp a 20 years' tussle, and our troubles are increasing rather than diminishing. The lamp cuts the same kind of a figure against the sky, as it did in the year 1875. Many details have been added in the interior construction—more magnets and more springs and more cut-outs and more chimneys, and less glycerine, but I do not think the statement can be denied that not one single idea of great merit has been added to the arc lamp between 1875 and 1895.

If this be true, is it not time to consider the question seriously? Are we to give up the question, and acknowledge that, hanging on our streets, is the world's best effort for the distribution of light through the medium of the arc lamp? Is evolution to be the password to progression in all the arts, in fact, in everything except the arc lamp?

To return to the opening sentence of this paper, "For the purpose for which it is intended to be used, the arc lamp as we commonly know it, is, mechanically and electrically, the poorest designed and constructed piece of mechanism on earth."

I am not here to decry the lamp of any manufacturer. It is, however, pertinent to say that any lamp which will allow the carbons to slip by or wedge, under any circumstances, is mechanically imperfect. It is an inherent defect in the lamp, and the damages or outrages should be charged to the manufacturer of the lamp. What mechanism has determined that the proper way to hold two slim, sharp-pointed pencils in a coaxial position is to fasten them rigidly at their extremities, 18 inches distant, and then depend on their sharpened points nosing each other correctly? A very much better way would be to leave the carbon holder loose and free, centering by guiding the carbons near the arc. This would make trimming a very easy matter, and admit of cross-eyed men being employed. On second thought, however, we run immediately into difficulties, for, as we cannot change the rate of consumption of the positive carbons, the arc would soon reach one of the guides and burn it away. This would then require a lamp with stationary arc, and that would require carbons of different diameters—upper and lower—and that would mean a great deal of thinking for the inventor and manufacturer, and so the lamps go out, and the station manager, believing that the arc lamp has been fully evoluted, keeps sending his orders to the manufacturer, and the manufacturer will never improve as long as he can fill his orders with old-style apparatus.

A sliding contact is a poor arrangement in an arc lamp. It has been tried as thoroughly as any idea ever could be tried. It is the direct cause of the roughness of the rod. The resistance of the contact is too easily increased by the presence of a little dust. The sliding contact in the arc lamp must go.

The carbon rod itself is a troublesome institution. With an annular ring for a clutch, it must be kept in a uniform polished condition, or it will give trouble. It is responsible for the unsightly, hideous chimneys, which ought not to be in sight, and yet which cannot be draped. As we are building a new lamp let us dispense with the carbon rod altogether. We can then cut off the chimneys, and shorten up the lamp. Then we can, without much trouble, parallel the carbons with the operating mechanism, and increase the percentage of useful length to total length to at least 80 percentage. With a short lamp we can make a casing of light cast iron in such shape as to avoid the necessity of a hood. We can also increase the carbon length, and if we do this, we can choose our own size of carbons—that size for upper which will produce the largest crater, and that size for lower which will best let the light out.

Thus we come back and meet, but overcome, our first difficulty. We construct a focusing lamp, and this leads us to the thought that there is only one correct position for the arc

inside the globe, anyway, and that the arc should be stationary. If we hang the upper carbon on a chain suspended over a sheave, and attach the lower carbon to the lower end of the chain, we can, with proper adjustment, accomplish many things. As the upper carbon feeds downwards as it is being consumed, the chain can be of equal weight—inch for inch therewith. Therefore, when an inch of upper carbon has been consumed, and its weight taken from the cross head, an inch of chain has been added, and the armature remains in the same plane between the pole pieces of the magnet as before. This is an absolute necessity where the same difference of potential is required throughout the entire range of burning.

Thus, we are not restricted by the weight of the carbon, and can use whatever size is most suitable. It having been demonstrated that with 8, 9, or 10 amperes, two ⅝-inch carbons will produce a larger crater and give more initial light than any other size, it remains only to determine the length necessary for burning 14 to 16 hours. This length has been found to be 14 inches. With an upper carbon of ⅝ inch x 14 inches, we find that ½-inch x 12-inch negative plain will burn an equal length of time, leaving an equal stub and keep the arc practically in the same position during the entire run. This small lower carbon will let out the intense light in the crater of the upper—the increase of light at 45 degrees being something which would astonish most experimenters.

We must not forget that 320 millions of money is invested in the central stations alone in the United States, simply to get light and more light with the same expenditure of energy should be a welcome statement by those interested.

By quotations from all leading carbon manufacturing companies of the country, the point is discovered that a pair of ⅝-inch x 14-inch and ½-inch x 12-inch carbons is the cheapest possible combination for 14 to 16 hours' burning. Any one can test this point. It is simply the price of one ⅝-inch x 14-inch plain and one ½-inch x 12-inch plain carbon against three ½-inch x 12-inch plain or 7-16-inch x 12-inch copper-coated carbons. I have quotations in my pocket which will make a difference of $2.50 per lamp per year, assuming the full number of burning hours nightly, in favor of the ⅝-inch x 14-inch and ½-inch x 12-inch carbons.

Again, a ⅝-inch upper and ½-inch lower, loose at the joints and guided near the arc, will absolutely prevent wedging or slipping by, whether the lamp be shunt or differential.

I quote from a recent article by Alex. Dow, of Detroit: "In the plant I operate, analysis of the 'outs' for two months showed that lapping was responsible for too much of the total trouble. We were running with 7-16-inch carbons in both holders. We changed to ⅝-inch uppers, retaining the 7-16-inch lowers. Results for four winter months' operation of 1,480 street arcs, is just one 'out' by lapping." Mr. Dow is ahead of the lamp he tried to fix. He neglected to state that he was compelled to break his ⅝-inch carbons off so that the weight would be more than a 7-16-inch x 12-inch. This lamp was not designed on evolution ideas. A heavier weight in the upper carbon holder would position the armature in a different plane as regards the operating magnet.

The double carbon lamp has outlived its usefulness. It filled a gap for a few years. Its only recommendation is that it will burn all night long. Its drawbacks are numerous. More mechanism is required: Two carbon rods with two sliding contacts. The arc is struck well up near the top of the globe at one side—not in the center—and travels downwards. This causes an uneven heating of the glass, which results in globe breakage, especially in severe climates. I have known a number of superintendents who always took the precaution to crack their globes with a soldering iron before putting on, then by putting on a net, the unequal expansion and contraction were overcome.

Never losing sight of the fact that the function of an arc lamp is to diffuse light—as much light as possible, and in every direction possible—any unnecessary opaque substance which is interposed between the arc and the surrounding space to be illuminated, shows a defect which is simply monstrous. With one pair of carbons burning 16 hours, we need have only one single arm of small cross section reaching down to sustain the globe holder. The shadow from this arm can be thrown directly against the pole or building, leaving absolutely unobstructed light for the street. We can arrange the trimming to be done quickly and without touching the globe. The globe can be cleaned without removing.

It is a very noticeable fact that those who have had the most intimate acquaintance with arc lamps and have operated practically the largest lighting stations for the longest time are the men who are the most eager to hear of a lamp constructed on new principles.

The West Side Park, Chicago, is about purchasing a large arc lighting plant—one of the largest ever installed at one time. They want 750 arc lamps. The specifications drawn by their engineer, Mr. Forée Bain, reached me a few days since. They are sufficiently unique to be preserved. His idea, I think, is new. He asks a number of questions. The bidder is to answer these questions on blanks furnished, said answers to form the guarantees of the bidders.

These specifications read, as follows:

Single or double carbon? Size of carbons? Upper, ...? Lower, ...? Cross section? Market price of such carbons per 1,000? Length of time the lamp will burn with one trimming, in circuit of 9.6 to 10 amperes and a difference of potential of 45 or 50 volts at terminals of lamps? With 6½ amperes and 45 volts? Will the lamp burn at a practically constant voltage of 45 to 50 volts while the current may be changed from 9.6 amperes to 6½ amperes? If not, what range do you guarantee? In stating guarantees above, do you refer to the use of plain or plated carbons? State make of carbons referred to. If such carbons are covered by patents, making them a monopoly, state price per 1,000 you hereby guarantee they will not exceed for a period of five years from date hereof? By what means are the carbons adjusted to a coaxial position? By what means are they maintained in a position coaxial with regard to each other? What is the extreme length of lamp? What is the weight of lamp with globe, trimmed and hung ready for operation, with hood and hanger board, if such be necessary? How many side rods for supporting the globes and negative carbons? Diameter of each intercepting the rays from the arc? Length? Is it necessary to remove or disturb the globe when trimming the lamp? Does your lamp require a special globe? If so, what price do you guarantee they will not exceed for a term of five years from date? Of what material is the jacket or case composed? How removed for inspecting the operating mechanism? Is the lamp shunt or differential? After the arc is struck, is the series coil retained in circuit? Is its responsive mechanism in continuous active motion? What is the electrical resistance of the series coil and its connection? what is the resistance of the shunt coil? Of what size wire is it composed in decimals of an inch? How many active pivotal joints in operative mechanism? How many springs in the lamp? How many variable adjusting devices are there in the lamp? Are they sliding or pressure? Of what metal composed? Maximum current carried? Can they be readily replaced? Will the automatic cut-out re-establish the arc when the carbons come together? Within the limit of what number of volts can the cut-out be adjusted to positively operate? If a double lamp, what is the difference of voltage between two pairs of carbons when in normal operation? Is any resistance cut into the main circuit when the lamp automatically cuts off? How many ohms? What is the form of cross section of the carbon feeding rod? How is the circuit through the rod? What is the area of surface contact of the clutch with the rod in decimal of square inch? What are the voltage and current at which the lamp is best adapted to operate? State the maximum voltage between which the lamp will operate and feed in practical service, during a period of six months? Mention any special features of your lamp?

The man who could ask those questions is hunting for an arc lamp different from the ordinary. They show that he has fought and bled with a multiplicity of spools, springs, rods, sliding contacts, lapping carbons, broken globes, and rusty sheet iron cases, and that he has lived within the dark shadows thrown by the old style lamps, and gazed for years upon landscapes marred by the contours of the arc lamps of the period of 1875 to 1895.

REPORT OF THE COMMITTEE ON STANDARD RULES FOR ELECTRICAL CONSTRUCTION AND OPERATION OF THE N. E. L. A.[1]

THE report drew attention first to the preamble and resolution adopted by the committee under which the various electrical, insurance, architectural and kindred interested bodies were invited to a joint meeting to discuss the subject, which is already familiar to our readers, and which led up to the conference held in New York, March 18 and 19, of this year. The report continues as follows:

Captain Brophy, by the request of your committee, had prepared and read a paper on the history of attempts at formulating standard rules by the National Electric Light Association and others, and your committee respectfully suggest that this paper be printed as accompanying this report, believing a record should be thus made of the important part played in the past by this association.

Your committee also submitted to the conference, as a basis for the discussion, a pamphlet containing the codes of rules which are largely in vogue in this country and abroad, emanat-

[1]Presented at the convention of the N. E. L. A., New York, May 5 and 7, 1896. Abstract.

ing from the following organizations: National Electric Light Association, National Board of Fire Underwriters, Associated Factory Mutual Insurance Companies, Phœnix Fire Insurance Company (English), and Board of Trade (English). Various other matters relative to American and foreign practice were presented at the conference, and after a most earnest consideration of the various codes and much valuable discussion covering a period of two days the whole matter was referred to the code committee of seven to prepare a final draft for submission to the next meeting of this conference, which was then adjourned to meet June 25 and 26, or subject to call of the chair.

Your committee feel that there is every reason to believe that the long sought for and much to be desired end is near at hand, and that the formation of the national conference upon standard of electrical rules will result in the near future in the adoption, promulgation and enforcement of one single recognized standard for electrical construction and operation; a standard code meeting fully the requirements and wishes of the electrical, insurance and allied interests of the country. Believing the interests of the National Electric Light Association will be conserved by the national conference, in which the association will doubtless continue its representation by an official delegate, your committee present herewith its final report and beg to be discharged.

Accompanying the report will be presented the voluminous correspondence of your committee and various other papers, three of the official code for the conference, full minutes of the conference held March 18 and 19, 1896, covering 179 pages of typewritten matter, and including Captain Brophy's paper, various committees' reports, etc., and thirty copies of the standard codes forming the basis of discussion at the conference.

In conclusion, your committee most strongly urge the association to continue its representation in the national conference, by the appointment at this meeting of an official delegate and the appropriation of a sum of money not to exceed $25 for carrying out the incidental expenses of the conference, other bodies contributing a like sum for this purpose.

William J. Hammer, chairman; Jas. I. Ayer, Harrison J. Smith, E. A. Leslie, Wm. Brophy.

ADDRESS OF PRESIDENT C. H. WILMERDING BEFORE THE N. E. L. A.[1]

MR. WILMERDING opened his address with a brief allusion to the history of the Association and referred to the history of the science as exemplified in the historical collection at the exposition. Referring to the rapid progress of the art he drew attention to the fact that since the World's Fair at Chicago in 1893, the world had been given Röntgen's discovery of the X-ray, the Tesla oscillator and Moore's vacuum tube light. He also referred to the transmission of the power from Niagara, which runs the Niagara model at the exposition, which traverses a distance of 462 miles, that is, 347 miles longer than the celebrated Frankfort-Lauffen transmission.

Coming to the commerical progress Mr. Wilmerding continued:

About seventeen years ago the first central station was established. At present there are 2,500 electric light companies in the United States and about 200 municipal plants. These central stations represent an invested capital of $300,000,000. There are, in addition, about 7,500 isolated plants, which have required the expenditure of $200,000,000 more. An idea of the capacity of these 10,000 installations may be formed when it is known that there are produced daily for their use from 50,000 to 75,000 incandescent lamps; that the annual consumption of carbons in arc lamps is 200,000,000, and that 500,000 stationary electric motors are operated by the current which they generate.

The electric railway is of still more recent birth, dating back but ten years, and yet at the present time there are no less than 900 such roads in this country, using 11,000 miles of track, operating 25,000 cars and involving an investment of about $750,000,000; and this investment is increasing annually at the rate of $100,000,000 for new roads and new equipment. While these are large figures, they do not at all represent the total capital employed in electrical industries. The manufacturers of the apparatus and supplies used to carry on this enormous business, and the dealers who handle them, have at stake probably a sum sufficient to build and equip all the central station plants in the country; and if the auxiliary enterprises, such as those of the producers of copper, the makers of boilers, the engine and car builders, fixture manufacturers, glass workers and a score of others, who depend in a large degree, and in some cases, exclusively, upon the electrical trade, are considered, the grand total would reach a sum that any country might be proud of as a national debt.

This astounding growth affords a striking example of American enterprise as compared with that of the Old World. Against 900 electrical railways in this country, there are less than 100 in all Europe; and as to electric lighting, the output of a single company in New York, or of a single company in Chicago, is greater than the combined output of all the stations in the brilliant city of Paris.

The short period since our last meeting has in itself marked an epoch of the greatest importance in electrical engineering, the Metropolitan, of Chicago, has been opened for public travel, and has already demonstrated that such a road can be operated at about one-half the cost of a steam road, and making it merely a question of time, and a short one at that, before all elevated trains must be propelled by the same cleanly and economical means.

The three first powerful electric locomotives of the Baltimore and Ohio Railroad have been put into regular service in the Baltimore tunnel, drawing the heaviest trains, and furnishing an example which other railway companies are already preparing to follow. This is undoubtedly the first step toward a general revolution in the methods of transportation which will result, not only in greater comfort and better service to the public, but in such a saving to the companies themselves as will place many a road, now on the verge of bankruptcy, on a prosperous and dividend-paying basis.

I am glad to be able to say that, while everything else electrical has been forging ahead, the National Electric Light Association has not been standing still. The reports which will be submitted by the Committee on Rules for Safe Wiring and the Committee on Data will show that they have accomplished much valuable work during the past year. The progress which has been made by the former committee toward bringing about the general adoption of a national code of rules for electrical installation is especially gratifying, and we may at last hope that this much-to-be-desired and long-deferred result of their labors may soon be attained. We have all suffered from the lack of fixed standards governing electrical construction and from the arbitrary rulings of self-constituted authorities on this very important subject, and the establishment of a board, composed of competent and representative men, whose rules will be consistent and, as far as possible, permanent, is one of the greatest of our needs, the realization of which should be one of the first aims of the association.

[1]Abstract.

PROF. ELIHU THOMSON BEFORE THE ELECTRIC POTENTIALS

LADIES' Night was celebrated by the "Electric Potentials" Wednesday, April 22, at the Thorndike, Boston.

The meeting was a great success in every way. There were about 100 ladies and gentlemen present. A reception was held previous to the dinner, and this was followed by a brief business meeting, at which twelve new members were elected. The officers for the coming year were also appointed, as follows: Frank Ridlon, President; G. W. Blodgett and H. F. Woods, Vice-Presidents; I. H. Farnham, Treasurer; Sydney Hosmer, Secretary.

After a most interesting résumé of the history of the Röntgen ray, glass globes were produced, their strucure explained, and the spots pointed out whence the Röntgen rays were flashed. As there were two different kinds of rays within the glass globes, it became necessary to use a sheet of lead to divide the one kind from the other. Having secured a globe that was in condition for producing the Röntgen rays, Professor Thomson proceeded to place two sensitive plates in a rubber hot-water bath. On this he placed a flat piece of wood, and on this another piece of wood into which a piece of wire twisted to form the word "Röntgen" was imbedded, the surface of the wood on the side next the wire being covered with a piece of pasteboard. This arrangement being subjected to the X-rays for a few minutes, the sensitive plates were treated by the usual photographic process of fixing and washing, when on being held to the light the word "Röntgen" was distinctly seen photographed on both plates.

Having briefly described the apparatus by means of which he transformed a low potential current to a very high one, and stated that it was possible to further increase the potential almost indefinitely, Professor Thomson proceeded to show by means of a powerful lantern impressions of his own, his assistant's, and his wife's hands, or rather the bones only, which were very distinct and utterly devoid of flesh, the rings on the fingers showing very prominently,

a diamond in one ring being quite transparent. Various fish, insects, reptiles, and other objects were also shown as reproduced by the Röntgen rays, all of which, in their weird and uncanny skeleton-like form created much interest in the audience, which, at the close of the address and experiments, gave Professor Thomson their hearty applause.

The occasion throughout was a notable one, there being present prominent and well-known electrical representatives from various parts of New England.

MR. H. L. FALK IS A FRAUD.

A FEW weeks ago, we published, with considerable caution and reserve, some alleged X-ray photographs of the brain taken by Mr. H. L. Falk, of New Orleans, who accompanied his data with references as to his truthworthiness. We hesitated to use the matter and did not do so until Mr. Falk sent us a further letter, asking for the publicity and recognition that were his due. Under these circumstances, with due disavowal of any faith on our part, we published his statements, "for what they were worth," but meantime sent to New Orleans and engaged a well-known scientist there to investigate the matter for us as fully as he could. We give his reply herewith, withholding only his name:

In regard to the so-called X-ray pictures of Mr. H. L. Falk, I do not hesitate to say that they are spurious, and that Mr. Falk is a perfect humbug. I went to his house and examined his apparatus and watched his work, and a more impudent impostor I never saw. Falk is an ignorant young fellow of about twenty-three or twenty-four years of age apparently, who has been an itinerant photographer and has dabbled a little in electricity. His apparatus consists of an old sixteen candle lamp and a medical "faradic" apparatus excited by five or six Edison-Lalande cells (so far as I could make out in the darkness under the table). He attaches one terminal of his secondary to the base of the lamp and then grasps the bulb with his hand and holds the bulb over the plate holder, keeping it in motion all the time. He gets the ordinary Geissler effect of a whitish glow in the bulb, but no trace of phosphorescence on the glass. I prepared a number of simple objects in a pasteboard box for him to photograph, but he was unable to do so. We made a number of tests, all of which showed that he was humbugging. Finally, one of the party, a prominent young physician, asked to have his brain taken, and after Falk had "prepared the plate" the young physician told him he would lie on his back and get that view. While Falk was going through his trick of moving the bulb all around above his head, he put his hand on his forehead, and left it there while the operation lasted. On development (I keeping the plate in sight until the development was complete and a friend of mine keeping his hand on it all the time), there appeared a side view similar to the one that I see published in The Electrical Engineer of April 29th! Every one present was convinced that the experimenter was a fraud.

I think the man places a drawing in contact with his plate while in the dark room, draws the shade from his lamp for a moment and makes an impression with ordinary light before bringing the plate out. He requires that he should be informed in advance exactly what is to be taken, claiming that the plates must be specially prepared for each picture. He is thoroughly untruthful. His statement was that his photographs were taken with wet plates and that his secret was in their preparation. To test this I drew the slide of the plate holder in the dark and found an ordinary dry plate. Falk never saw a Crookes tube, nor an X-ray negative. I invited him to come to my laboratory and see the apparatus, but he never put in an appearance. What his object is in this falsification, I do not know. I have not exposed him publicly, as I thought he would make no further pretensions after that evening. His audacity seems unbounded.

MR. D. M. STEWARD, the president of the Chattanooga Chamber of Commerce and manufacturer of lava insulators and other celebrated specialties, has been traveling in Europe, and is sending home some very interesting letters to the Chattanooga "Times." His enthusiasm over Scotland shows pretty clearly which side of the border he and his ancestors came from. We venture to believe he strikes the Scots as a fine type of American.

LITERATURE.

"DIE ANKERWICKLUNGEN UND ANKERKONSTRUKTION DER GLEICHSTROM-DYNAMOMASCHINEN" (Armature Winding and Armature Construction of Continuous Current Dynamos), by E. Arnold. Berlin, 1896, J. Springer, second edition, 312 pp., 5½ x 8. Price $3.

The present volume is an extension of the author's previous work on a subject which must always be of interest to the designer of dynamo-electric machinery. In glancing over the pages we notice a departure from the treatment which the subject has received in the first edition; thus, in the latter, the author divided armature windings into those having parallel, series and mixed windings. Further study has shown that a better classification is possible, in so far as the mixed windings can be divided into a number of parallel and series parallel arrangements.

The second part of the work, relating to armature construction, has been greatly enlarged, as compared with the first edition, and with much benefit to the reader. The author treats the subject by no means from the academic standpoint, but has introduced the valuable feature of accompanying all detail drawings by scales of dimensions, so that the student and designer is able to draw the greatest benefit from the illustrations. The work is profusely illustrated, and contains information on the latest types of machines. Its entire get-up is most creditable, and in its way it is among the best of its kind which has yet come under our notice.

"COMPUTATION RULES AND LOGARITHMS WITH TABLES OF OTHER USEFUL FUNCTIONS," by S. W. Holman. New York, 1896, Macmillan & Co., 73 pp., 6½ x 9½. Price $1.

It is one thing to have a set of tables of logarithms, sines and other trigonometrical functions and another to be able to use them properly. It is the author's intention to put into the hands of engineers and laboratory workers a set of tables which, without being too cumbersome, will permit of the carrying out of computations with sufficient exactness for all, except, perhaps, those undertaking astronomical work, and for that purpose he has limited his logarithms to five places of decimals, which, as he quite properly contends, effects considerable saving in time where numerous calculations are required. Perhaps as valuable as any part of the work are the 45 pages which the author devotes to explaining the use of the various tables. This is a boon, not only to those who have heretofore been without knowledge on the subject, but even to those who have become a little rusty on the subject from long disuse of such tables. The author gives an actual example, worked out, illustrating the use of each table. At the end of the work we find a résumé of the physical constants of nature. The tables are set up in large, clear type and printed on heavy paper.

"TRANSFORMATOREN FUER WECHSELSTROM UND DREHSTROM" (Transformers for Alternating and Polyphase Current), by G. Kapp. Berlin, 1895, J. Springer, 205 pp., 5 x 8. Price $3.

While there are works on dynamo electric machinery a-plenty there is, strange to say, little independent literature on transformers, which is all the more strange, considering the important place which this type of apparatus now occupies in electrical distribution. It is, therefore, gratifying to note the appearance of a work especially devoted to this subject, and the more so when the subject is handled by so able an engineer as Mr. Kapp.

The author has treated the subject from the eminently practical standpoint. Beginning with the general theory of transformers, he carries us through the methods of construction, showing the best distribution of copper and iron, both as to efficiency and cost of material, not neglecting those small details of construction which so frequently are the making or the marring of a piece of apparatus intended for hard usage. Special chapters are devoted to the testing of iron intended for transformers, as well as for the final output and efficiency tests of the completed apparatus. A chapter is also devoted to the methods of equipping transformer sub-stations, which is accompanied by a number of useful diagrams, as well as to methods of regulation of transformer circuits. The final chapter is devoted to the description of the latest types of two and three-phase transformers, especially the latter, many of which are accompanied by detailed drawings. The part devoted to the calculations is well within the grasp of those of limited mathematical knowledge, while even those lacking the bare elements will find in the work much useful information. We hope that the promised English translation will soon make its appearance.

MISCELLANEOUS.

THE JACQUES CARBON CONSUMING PRIMARY BATTERY.

IN our issue of March 11, we described a primary battery invented by Dr. W. W. Jacques, of Boston, in which the positive element, that is, the one consumed, is carbon. This cell is shown in section in the accompanying diagram, Fig.

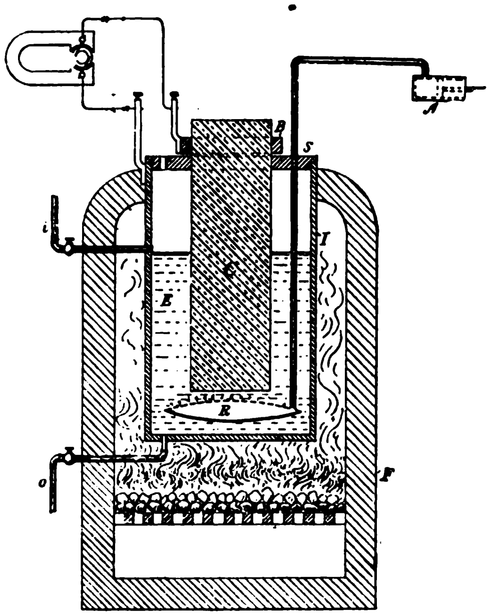

FIG. 1.—THE JACQUES CARBON CONSUMING PRIMARY BATTERY.—SECTION.

1. The carbon, C, is immersed in a caustic soda solution, E. A pump, A, forces air into the rose, R, which distributes it evenly into the electrolyte. The solution is contained in the Norway iron pot, I, which forms the positive terminal, the negative, B, being clamped to the carbon, C, which is supported by the insulating cover, S. The caustic soda solution is admitted and removed by the pipes, i and o. The whole is surrounded by a furnace, F, which maintains the active cell at a temperature of 400 to 500 degrees Centigrade.

The accompanying illustration, Fig. 2, shows a corner in Dr. Jacques' experimental laboratory. An early form of the carbon electric generator, which has now been in operation for six months, is seen to the left, the tops of the 100-cell battery showing, with their connections. To the right of this is the air pump, driven by a portion of the current generated, and above it, on the wall, part of the electric lamps operated. The two switches on the small shelf are used, the one for switching that portion of the current used for the pump, the other for cutting the lamps in and out of circuit. The cells consist of iron pots 12 inches deep and 1½ inches in diameter.

In a recent test made by Messrs. Stone & Webster, of Boston, the apparatus illustrated maintained 30 16-candle-power lamps at full brilliancy. It was found that to maintain these lights for 18¾ hours required the consumption in the pots, by oxidation, of about 8 pounds of carbon. The average pressure during the test from the 100 cells was 90 volts, and the current 16 amperes. Messrs. Stone & Webster report that the electrical energy actually obtained from the carbon consumed in the pots was 82 per cent. of the theoretical.

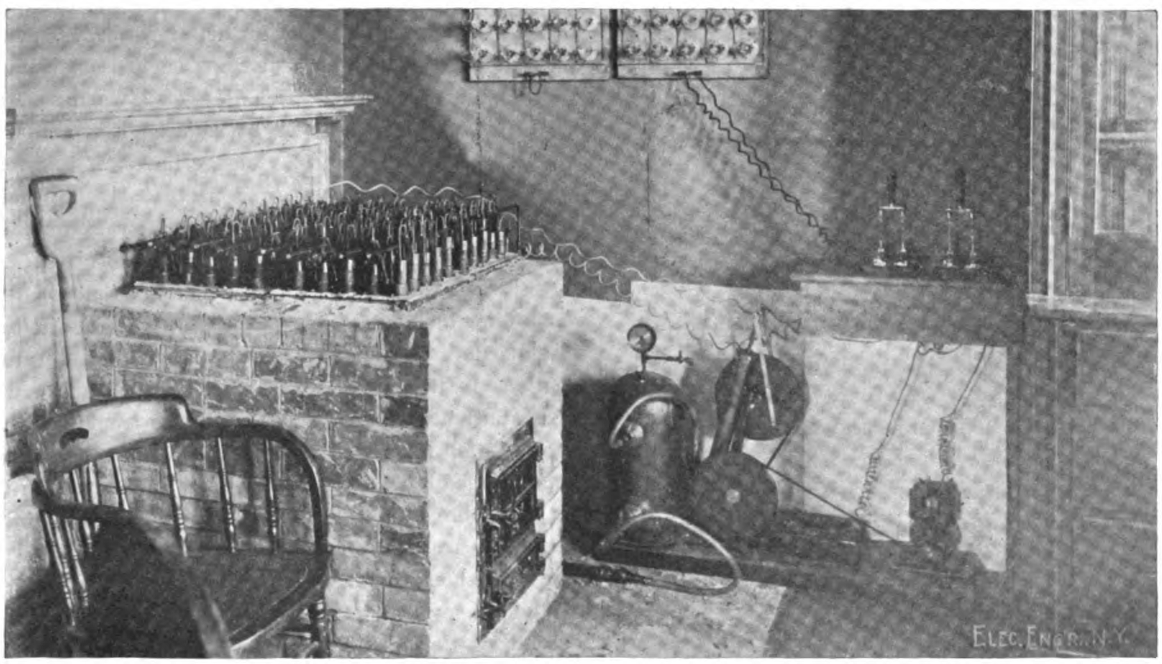

FIG. 2.—THE JACQUES CARBON CONSUMING PRIMARY BATTERY.—VIEW IN DR. JACQUES' LABORATORY.

WORCESTER POLYTECHNIC INSTITUTE.

The above Institute, of which Dr. T. C. Mendenhall is now president, has just issued its annual prospectus and catalogue for 1896. As a pioneer technical school, Worcester has kept well in the van, and to-day its personnel and equipment make it a very attractive place for technical studies in the broad engineering field. Students who aim at rounded work in the various branches of mechanics, civil engineering, electricity and chemistry, are likely to find at Worcester their opportunity for the best training in physical science and application.

FRESNO CITY PUMPS RUN BY ELECTRIC POWER TRANSMITTED 35 MILES.

The pumps at the city water works were run by electricity for the first time on April 14. The new company, which is bringing the power from the San Joaquin River, thirty-five miles distant, has turned on the current. A test was made several days ago with the lights, and since then additional machinery has been put in, and a 75 horse-power pump was run as smoothly as if it weighed but a few pounds.

ELECTRIC MOTOCYCLES are proposed for the park at Lake Harriet, Minneapolis. The idea is to run large carriages, capable of carrying twelve persons each. A floating race track for bicycles, lighted electrically, is also proposed.

THE WILLIAMSPORT WOODEN PIPE CO. have an exhibit of their creosoted wooden conduit, steam pipe casing and crooss arms, at the Exposition.

CONTENTS.

A GREAT EXPOSITION.

The exposition now being made at the Grand Central Palace, in this city, by the National Electrical Exposition Company, under the auspices of the National Electric Light Association, is already a pronounced and emphatic success. A localized show which attracts about 50,000 people in its first week, when many of its features of interest have not been brought into action, has evidently many considerable merits. As a matter of fact, while other electrical expositions may have excelled it in one element or another, in its general average of excellence and artistic setting, this is conceded to take the palm. At Philadelphia, in 1884, electric lighting dominated, as at Paris earlier. At the World's Fair the generating plant was practically all located outside the Electricity Building, and that place was one of the dullest, as to moving machinery, in the whole great show, and never other than chilly in its aspect. At the Grand Central Palace the general aspect is wonderfully brilliant and warm in its coloring, while the generating plant is all in the big basement, down one flight of stairs. Compactness counts for a good deal when there are large numbers of exhibits to look at, and fortunately at the Palace condensation has been the "mot du jour." Nobody has gone in for hugeness, and yet there is the cream of the most modern products in electricity, as well as a historical collection that is hardly likely to be duplicated in this country.

The features of interest in this choice show are so numerous it is difficult to particularize. The generating plant, however, with its battery of boilers of some 600 horse-power, run by a pretty woman, and its string of some fifteen different direct connected units of engine and dynamo, is certainly worthy of the attention of every steam and electrical engineer. "Direct connection" has never before made so emphatic a demonstration in this country of its quality and possibilities, and while there is still abundant room for better work, it is evident that the "unit" type has won a place as a very useful advance in the art of current generation. Next as worthy of attention come the varied applications of motor power, and with these might be ranked the display of arc lamps of latest form, especially for multiple work, and particularly the inclosed arc style. The latest results with this, widely exemplified at the show, are most pleasing and satisfactory.

Every electrical engineer will find his time well spent in examining the remarkable collection from the United States Patent Office of some 365 models illustrating the greatest inventions in the respective leading lines. Equally worthy of close study are the historical collections from Mr. Edison and Prof. Elihu Thomson, and the collection of incandescent lamps loaned by Mr. W. J. Hammer. And as though this were not all, there is a superb collection of experimental and research apparatus from leading schools and colleges that one can spend hours over.

We need say little of such interesting things as Mr. Edison's exhibit of the Röntgen X-ray effects, Mr. Moore's vacuum tube lighting, the Niagara Falls transmission of power and sound, the operative model of the Erie Canal electrified, etc. These will attract easily, but underlying these and as adjunct to them is a mass of solid commercial and industrial exhibits

that is a credit to the art and a splendid augury for its future prosperity.

AN INTERESTING CONVENTION.

It was feared by many that the exposition would by its interest and charm swamp the convention, but the effect was just the contrary. The meetings have rarely been so well attended, and the interest was far above the average in many ways. Mr. Wilmerding is to be congratulated upon so brilliant a close for his memorable year of office, and Mr. Nicholls upon succeeding to the presidency at a time when the association has shown itself to be so strong and vital and progressive. The choice of such high-grade men as these for the officers of the association is of itself a guarantee of good work which "betters what is done."

The discussions which nearly all the reports and papers submitted to the convention called forth were almost uniformly as interesting and valuable as these contributions themselves; indeed, the failure of a committee to report brought out one of the liveliest discussions had during the convention. We refer to the Committee on Relations Between Manufacturing and Central Station Companies. We fully agree with those members who believe that if ever there was a time when such a committee can be of use to the association it is the present. With the combination among the largest manufacturing companies now existing, the central station owner may well look forward to the future with misgivings, if he remain inert. Complaints are constantly heard on all sides of unfair treatment of central station companies that were organized under promises of protection, but which promises are now sought to be evaded by alleged inability to control the action of individual members of the "combine." But we believe that these matters can be remedied and that if a vigorous and aggressive policy were adopted by the National Electric Light Association the manufacturing combination would be compelled in sheer self-defence to alter its present obnoxious methods. Mr. Beggs has well said that 2,700 central stations ought to be powerful enough to compel respectful consideration. He might have gone further and added that in default of such consideration these central stations themselves might combine and do their own manufacturing on a coöperative basis. It is on open secret that such a plan has been considered in several quarters by companies taking a considerable percentage of the output of the combination's factories. We trust that for the good of all concerned such a step may not become necessary, nor will it, if the association makes the best of its opportunities; but that some action, and that of the most vigorous kind, will be necessary to prevent it, is open to little doubt.

A notable feature of the proceedings was the almost total absence of all reference to the incandescent lamp. Whether this be due to the fact that there is little to be said on the subjct or that central station managers are now more actively engaged in pushing arc lighting on their constant potential systems, the fact remains that the arc lamp practically obsorbed all the attention given to lighting. Mr. Rogers' paper certainly put the subject in a strong light, and some of the home truths embodied in his paper can hardly be called flattering to the arc lamp-makers of the past twenty years. The recent marked improvement, both in the construction of arc lamps and in the adoption of the inclosed arc, has certainly served to place the arc lamp a long way ahead in the scale of usefulness; and, if any doubts on this subject still exist in the minds of electric light purveyors, a visit to the electrical expostion must soon dispel it. It is now only a question of a short time when the enclosed arc will be adapted to series lighting circuits, and when the day of the double carbon lamp will be at an end. It will not be greatly missed, nor will its memory call forth pleasant recollections. It will have served its purpose, and, like many other very useful devices in the modern electric arts, may find a last resting place in the scrap heap and in historical collections.

Power distribution by alternating current, judging from the discussions of Mr. Emmet's and Mr. Leonard's paper, is still one of the uppermost questions of the day in central station circles. The flexibility of the modern polyphase system, so well shown in Mr. Emmet's paper in undeniable, and the really remarkable output of such apparatus placed by one company within the past three years is worthy of all praise. But it was evident throughout the discussion that what most of the members present were longing for was a motor that could be operated satisfactorily on their present single-phase circuits. It seems strange, indeed, that with all the talent and experimental facilities at their disposal, the large manufacturing concerns in the country have thus far failed to produce such a machine. We are glad, therefore, to note the recent progress alluded to in Mr. Leonard's paper, and the work now being done in other directions looking to the same end.

THE INFANT.

If there is one thing more than another that tires the plain electrical man, it is to be told that his field of work is chiefly characterized by its juvenility. Some remarks he can stand, but that always upsets his equanimity, and he does not need to have read through Dr. Park. Benjamin's fine collection of early electrical literature to justify him with evidence to the contrary and warrant for his protest. Scientifically considered, the art is very old, and when it comes to industrial statistics, it is certain that electricity has plenty to produce. Just at this juncture, when the public is talking electricity "for all it is worth," it may not be out of place to present a few familiar but concrete facts showing what electricity has actually done. For example, in the United States to-day there are 65,000,000 telegrams sent every year. The telephone exchanges of the country take care of 750,000,000 telephonic conversations every year. There are 2,700 central electric lighting stations in the country, and some 7,000 isolated plants. There are not less than 15,000,000 to 20,000,000 incandescent lamps burning in this country, and the number of arc lamps reaches toward a million. Nobody knows exactly how many motors have gone into use, but if we include fan motors, the figure must certainly touch 500,000. The trolley roads of the country reach 1,000, with 12,000 miles of track and 25,000 cars. The investment in mining plants is estimated to have reached $100,000,000, and in electrical power transmission $50,000,000. All told, the capital represented in the various electrical industries to-day is fully up to $1,500,000,000, all fairly well earning in the main, and much of it handsomely. At least 2,500,000 people in the United States are directly or closely dependent upon electricity for their livelihood and sustenance.

NINETEENTH CONVENTION OF THE N. E. L. A.

MAY 5.—MORNING SESSION.

THE nineteenth convention of the National Electric Light Association was held at the Grand Central Palace, New York City, May 5-7, 1896. President C. H. Wilmerding, of Chicago, presided, and Secretary George F. Porter was in his customary place. On the platform were Vice-Presidents James I. Ayer, Edward A. Armstrong and M. J. Francisco.

After welcoming the members the president delivered the following address:

The president then declared the convention open for the transaction of business, and called upon the various committees for their reports.

Chairman De Camp, of the Committee on Relations between Manufacturing and Central Station Companies, stated that the committee had no report to make, and asked for its discharge on the ground that there was nothing for it to do. This brought about a lively discussion. Mr. Beggs believed that there was a great deal which the committee might accomplish for the good of the association; indeed, he considered it one of the most important features for which the association was organized. In fact, at this very time when combinations were being made among the manufacturing companies, it was more than ever of vital importance that the operating companies whose purchases amounted to hundreds of thousands of dollars annually should be closely banded together for their own protection.

Judge Armstrong, with fine sarcasm, indorsed Mr. Beggs' views on the necessity of such a committee, and instanced a case in his own experience in which his company had been oppressed by a large manufacturing company, "the magnificent and a large one, the General one," and, after two years' waiting for an "adjustment" of the matters complained of, was still waiting. He took issue, however, with Mr. Beggs on a point made by that gentleman, that the association was of no benefit to its members. On the contrary, Judge Armstrong declared that he had always benefited by his attendance at the conventions and by rubbing up against others in the business and profession.

Mr. De Camp, in extenuation of the absence of a report, stated that when the committee was organized it was expected that those who had grievances would make them known to the committee, but no one had ever brought any such matters to the attention of the committee. Mr. Beggs expressed the opinion that Mr. De Camp had formed an entirely erroneous conception of the objects of the committee, which were of a general character, and not intended to take cognizance of specific cases alone. He instanced a case in which a similar committee of another organization had obtained relief for grievances from a large manufacturing company within thirty days after the organization of the committee. His idea of what a committee of this kind would be was to take up the broad question of the honesty and fairness of the manufacturing and parent companies throughout the country in going into territory simply for the purpose of exploiting apparatus and of wrecking capital. He was there to say that if this organization of central station men from all parts of the country would take hold of the matter actively, Mr. Francisco would not be compelled to sell arc lights at $2.33 per month to burn until 12 o'clock every night in the year, simply because some company owned by these parent companies sought to obtain franchises, and to which company the manufacturing companies desired to sell a new outfit in that city. This was not an exceptional case, by any means. The results, possibly, were more disastrous than in other cases, but he saw sitting there a number of gentlemen who were laboring under similar conditions today. That was his idea of what a strong, aggressive committee should be to deal with the general question between the central station people who composed the N. E. L. A. and the various State organizations that were springing up now and the general manufacturers. I tell, you, gentlemen, said Mr. Beggs, that you to-day represent possibly a hundredfold the amount of capital that is represented by these large new-order manufacturing and parent companies. I will withdraw my opposition to the disbanding of this committee, if it was formed by the purpose as stated by Mr. De Camp, because I do not see any force in that, but I believe that a committee should be appointed and continued, and held accountable to make a report to this organization, and that report to mean something. I certainly think that it is a very great necessity.

Judge Armstrong stated that to avoid misunderstanding his motives, he was not only willing, but anxious that some committee should be appointed to carry out all that Mr. Beggs desired, and that the most drastic measures should be resorted to in furthering the objects for which the committee was appointed.

The motion to discharge the committee was carried, and the meeting adjourned to 3 p. m.

MAY 5.—AFTERNOON SESSION.

The President opened the session by reading letters from Mr. Tesla, wishing success to the convention, and from Mr. T. D. Lockwood, an honorary member of the association, expressing the hope that he would be able to attend the latter part of the sessions. An invitation was also extended to the members to visit the roof of the American Surety Building; also one from Mr. R. R. Bowker, for the members to inspect the new stations of the New York Edison Electric Illuminating Company, and from the Crocker-Wheeler Electric Company to visit the company's works at Ampere, N. J.

Mr. L. A. Ferguson then read a paper entitled "Acetylene Gas."[1]

In the discussion which followed, Mr. F. Nicholls stated that from his experience he did not believe it would be safe to ship carbide of calcium in barrels. He knew the slightest moisture seemed to affect it, and in much the same manner as lime is affected by moisture. One drop of moisture on acetylene causes the gas to generate quickly; and if that came in contact with a flame, with a lighted match, or anything of that kind, in case it were alongside of a freight car, for instance, he thought it might prove disastrous. He had had no practical experience in the matter, other than having seen the effect of it in that way; he inquired of Mr. Ferguson if he had examined it in that aspect of the case.

Mr. Ferguson did not think anybody had had any experience in the actual shipment of carbide of calcium, but he had no doubt Mr. Nicholls was quite right in his assumption. The estimate he had made in his paper was probably very low as to the cost of barrels and the cost of shipment, but as it was such a small item, he thought he would put it on that basis, which would cover the cost of ordinary barrels of sufficient strength to contain calcium carbide; whereas, in all probability, in actual practice, one would have to use hermetically sealed tins or irons of some kind.

Mr. Beggs said that Mr. Ferguson's paper was the most exhaustive which he had ever yet seen on the subject, and moved that it be printed at once and circulated among the members of the association. Carried unanimously.

Mr. F. H. Leonard then read his paper on "Single-Phase, Self-Starting Synchronous Motors."[2]

Mr. H. A. Wagner inquired as to the effect of switching at the central station on the operation of the motor when running at full load. He had had such motors in operation covering a period of three years, and found that it was an almost insurmountable objection to the use of the synchronous motor, as the frequent switching found necessary to properly divide the load on alternating current generators caused the motors to fall out of stop.

Mr. Leonard replied that what Mr. Wagner said was quite true. If a motor fully loaded has the current switched off, it will slow down to a point so much below synchronism that it is impossible to go on, unless the switch is reversed so as to put it in the position of starting. In most stations where these motors have been used, the circuits on which the motors are run are not switched, except at hours when the motors are not in service, or it is done while the machines are in multiple, preventing the breaking of the circuit and the cutting off of the current. Mr. Van Trump inquired if there was not some difficulty in operating these motors due to a difference in the curve; that is, in the wave-line of the motor differing from that of the generator. He had met with such trouble in practice with synchronous motors. Mr. Leonard replied that these motors were wound, as stated in his paper, with a concentrated, that is, an ironclad winding. The wave-line made no difference.

Mr. Ferguson inquired whether, in case the machine was started up on a light load, and the operator did not fix the switch in time to allow the machine to accelerate its speed, it would not go all to pieces. Mr. Leonard replied that such would be the case, but explicit instructions to avoid this accompanied each machine, and if an attendant allowed it to happen once he never did it again. (Laughter.)

Mr. Wagner again referred to the difficulty in the operation of synchronous motors due to the switching at the station, and that while this would not occur in alternating stations in which machines were coupled in multiple, unfortunately very few, if any, stations were so operated at the present time. Mr. Leonard stated that in practice very little difficulty had been encountered on that score. It seemed to him that it could readily be arranged so that feeders supplying the motor power could be handled in such a manner that it would be unnecessary to switch very much during motor-load hours. In any

[1] See page 489.

[2] See page 491.

event, it was but a matter of a few seconds to start the motor up again, and as there was a great demand for such a motor, people were willing to put up with a slight objection, and to adjust the conditions so as to avoid the difficulty.

Mr. Wagner stated that he did not make his criticisms as reflecting at all upon Mr. Leonard's motor, but merely from the fact that he had had motors of exactly the same type in operation for the last three years, and had finally decided that he would have to give up work on that line, as such objections seemed to be insurmountable in ordinary practice. He admitted that he failed to solve the problem himself.

Mr. A. Churchward then read his paper on "Equalizer Systems of Distribution."[1]

Mr. C. L. Edgar, in the discussion which followed, declared that these systems in general all had one weakness, depending upon one inherent difficulty; every one of them, as he understood it, would go to pieces if the neutral wire came in contact with the outside wire; all the lamps on the outside would burst. Mr. Churchward denied this action. Mr. Edgar stated that he had tried the same experiment three or four years ago, but got into the trouble mentioned. Mr. Churchward said that the same point was made when he started out, but he had been looking for it in vain ever since. He did not claim any economy for the system, but advocated it merely as a method of getting around the three-wire system.

Upon motion the convention went into executive session, and then immediately adjourned the executive session until after the close of the next morning's meeting.

MAY 6.—MORNING SESSION.

The president called the meeting to order at 10:30, and announced as the first business the reading of the paper by Mr. W. L. R. Emmet, on "Results Accomplished in Distribution of Light and Power by Alternating Currents."[2]

A lively discussion followed which occupied the rest of the session, and which was participated in by Messrs. Wagner, Emmet, Ayer, Scott, Van Trump, De Camp and others. Owing to our crowded condition we are compelled to postpone the report of this interesting discussion until next week.

Before adjournment a letter was read from Prof. Elihu Thomson, regretting his inability to be present at the meeting. Adjourned to 2 p. m.

MAY 6.—AFTERNOON SESSION.

Vice-President Nicholls called the convention to order.

Judge Armstrong read a paper on "Evolution of Interior Conduits from the Electrical Standpoint,"[3] by Luther Stieringer. In the absence of the author the discussion was postponed, and a vote of thanks passed for Mr. Stieringer's able paper.

Mr. John A. Kelly then read a paper on "The Evolution of the Inductor Alternator."

Dr. Louis Bell characterized Mr. Kelly's paper as a peculiarly effective résumé of the work that had been done on this very simple machine. Perhaps the reference in Mr. Kelly's paper which most interested him was that relating to the sine-wave controversy. It has been pointed out by some investigators that the distorted wave is capable of giving better results with static transformers, slightly better efficiency, than a sine-wave of the same frequency. The effect on the transformer is very closely similar to that which would be obtained by taking an alternator that gives a true sine-wave and slightly raises the frequency. With inductor motors nearly all experimenters seem agreed that what difference there is between the alternators having a sine-wave and those that have not a sine-wave, is in favor of the former.

The report of the Committee on Rules for Safe Wiring[4] was then read by Mr. W. J. Hammer.

Mr. Seeley moved that the committee's report be received and spread upon the minutes, and a vote of thanks extended to them for their arduous labors, and that the committee be discharged. Motion was carried.

A long discussion ensued, which was taken part in by Messrs. Armstrong, Hammer, Ayer, Brophy and others, and ended in Judge Armstrong offering the following resolution:

Resolved, That a committee of five be appointed by the President on Standard Electrical Rules, which committee may designate some one to confer with the representatives of other bodies on the same subject, with power to expend not exceeding $25 annually. The resolution was carried.

Mr. Ayer offered the following resolution:

Resolved, That a committee be appointed by the president to confer with a similar committee of the Amer. Inst. of Electrical Engineers to effect a standard of candle-power for incandescent lamps. The resolution was carried.

In answer to the question of a member, whether the electric light companies could be classed as manufacturing companies under the statutes, Mr. De Camp stated that the Pennsylvania State Supreme Court had decided that such companies were not manufacturing companies. Another member stated that this matter had been brought before the Gas and Electric Light Commission in Massachusetts, and their decisions were that electric light companies were manufacturing corporations. Whether the courts had backed that up or not, he did not know.

The convention then went into executive session.

MAY 7.—MORNING SESSION.

The President called the meeting to order at 10:35 o'clock, and appointed the following gentlemen a Committee on Nominations: Messrs. Armstrong, Leslie, Francisco, Giles and Huntley.

A communication was read from John Caird, Principal and Vice-Chancellor of the University of Glasgow, and Sir James Bell, Bart., Lord Provost of Glasgow, inviting the Association to send a representative to the Lord Kelvin Jubilee next month. President Wilmerding appointed Mr. T. Commerford Martin to represent the Association. The appointment was ratified and Mr. Martin was instructed to prepare and to present to Lord Kelvin a set of resolutions on behalf of the Association.

Mr. Seely as chairman of the Finance Committee made the following report, showing financial transactions during the year as follows:

Receipts	$6,485.41
Expenses	5,746.76
Balance	$736.65

The assets of the Association are $1,792.94; active members, 111; associate members, 90.

A lengthy discussion ensued as to the time which should be included in the report of the Finance Committee; the report made having been brought down to the first of January, 1896. It was decided, as the result of the discussion, that the report should be made to include all financial matters up to within thirty days of the meeting.

A letter from Mr. Edward H. Johnson, of the Interior Conduit and Insulation Company, was read inviting the delegates to witness a demonstration of a new system of surface contact for street railways in the Exhibition Hall.

The president made the following gentlemen a Committee to confer with the American Institute of Electrical Engineers for the purpose of Determining a Standard Candle Power for Incandescent Lamps: Louis Bell, chairman, James I. Ayer and Louis A. Ferguson.

The president appointed William Brophy, chairman; C. B. Barnes, William J. Hammer, James I. Ayer and Mr. C. L. Edgar a Committee of five on Standard Electrical Rules; which committee may designate some one to confer with the representatives of other bodies on the same subject; with power to expend not exceeding $25 annually.

The report of the Committee on Data was then presented.

Mr. Swetland asked for the discharge of the committee, as in its present form the results of the committee did not pay for the time spent on the work. Judge Armstrong and Mr. Beggs advocated the continuance of the committee's work but limiting it to the statistics of a number of standard stations of different types. The following resolutions were offered by Judge Armstrong:

Resolved, That the Executive Committee be directed to expend such an amount of money as may be necessary to procure data from representative companies for the benefit of the committee. Carried.

A letter from the United Electric Light and Power Company was read, inviting the delegates to visit the new central station of the company at the foot of East 28th street, New York City.

Mr. Alfred Swan was down on the programme to open the discussion on "A Standard Socket." He was not able to be present, and submitted a communication on the subject.

The paper by Mr. H. L. Rogers on "The Evolution of the Arc Lamp," was read.[1]

The paper was listened to very attentively, and created much humor at times. Judge Armstrong said that he had heard some modest man behind him say that this was the cheeriest and most interesting paper that had ever been heard at one of these conventions. He felt that the good suggested which might come from the paper was something that merited the heartiest thanks, not only of the electric light men, but the never dying, ever present, ever active individual referred to in the paper—the taxpayer. The motion of thanks was carried.

The President then called on Captain Brophy, who made a short address on "Electrolysis," in which he traced the history of this evil and the remedies to be applied to avoid it.

The meeting then adjourned to 2.30 p. m.

1) See page 481. 2) See page 482.
3) See page 486. 4) See page 494.

1) See page 492.

MAY 7.—AFTERNOON SESSION.

The first business was the reading of the paper by Mr. Albert A. Carey, on "Steam Boilers; their Equipment and Management." Mr. Carey illustrated his paper with drawings on the blackboard.

The convention then went into executive session.

Mr. Seely, as chairman of the Finance Committee, made a supplemental report, in which he stated that the total cash on hand in the treasury of the association at the present time was about $5,000.

The following resolution was passed:

Resolved, That the Executive Committee be instructed to require that all papers to be read before the convention be first submitted for their approval, and if approved, that such papers shall be printed and placed in the hands of the members at least one week before the meeting, when such papers shall not be read in full, except by special order, that the time occupied in reading such papers may be devoted to the discussion of said papers.

The Nominating Committee presented the following names for officers of the association for the ensuing year:

President, Frederic Nicholls, Toronto, Canada.

First Vice-President, Henry Clay, Philadelphia, Pa.

Second Vice-President, J. J. Burleigh, Camden, N. J.

Members of the Executive Committee for three conventions, A. J. De Camp, Philadelphia, Pa.; John A. Seely, New York City; A. M. Young, Waterbury, Conn.; H. A. Wagner, St. Louis, Mo., to fill the vacancy caused by the election of Mr. Nicholls to be president.

Mr. Wilmerding, the retiring president, expressed his gratification at the manner in which the convention had passed off, and thanked the members for their assistance in contributing to its success. On motion of Mr. Seely, the secretary was instructed to prepare a set of resolutions to the retiring president for the manner in which he presided over the meeting. Mr. Nicholls, the newly-elected president put the motion, which was carried, and the meeting then adjourned sine die.

We give below a list of the names of the out-of-town attendants at the convention. To give a full list of the New Yorkers present is a sheer impossibility. Everybody was there.

ADAMS, N. Y.—W. L. Pratt.
ATLANTA, GA.—N. Y. Edgar.
BALTIMORE, MD.—J. W. Ellard.
BANGOR, ME.—J. N. V. Lane and W. E. Pierce.
BINGHAMTON, N. Y.—S. D. Cushing.
BRATTLEBORO, VT.—F. Taft.
BRISTOL, PA.—Charles E. Scott and Benjamin J. Taylor.
BRYAN, O.—W. A. Sheldon.
BOSTON, MASS.—H. L. Albright, C. C. Allen, G. M. Angier, James I. Ayer, M. H. Barker, W. S. Barker, C. E. Bibber, James Bradley, H. H. Brooks, Capt. William Brophy, J. F. Bubert, C. B. Burleigh, A. R. Bush, Arthur E. Childs, A. T. Clark, J. Comelliard, S. B. Condit, Henry B. Cram, B. W. Cutter, H. M. Daggett, Jr., Geo. W. Davenport, C. B. Davis, D. W. Dunn, C. L. Edgar, P. Fahey, W. J. Ferris, T. W. Flood, F. A. Gilbert, H. F. Golsin, C. E. Gregory, C. S. Haley, J. Y. Hamby, H. C. Hawks, W. P. Hill, W. S. Hill, C. W. Holtzer, Sidney Hosmer, A. L. Ives, A. B. Jenks, F. M. Kimball, G. A. Lancaster, E. C. Lewis,, T. D. Lockwood, Norman Marshall, J. H. Mason, J. M. Orford, Sidney B. Paine, H. C. Patterson, C. B. Price, C. J. Reilly, P. M. Reynolds, Frank Ridlon, R. F. Ross, T. C. Sias, F. B. Smith, H. C. Spaulding, F. B. Sweet, Calvert Townley, Donald F. Urquhart, G. W. Ward, C. A. White, James Wolff, F. B. Witherbee, C. J. H. Woodbury and A. Arthur Ziegler.
BUFFALO, N. Y.—C. R. Huntley, G. Urban, Jr., and W. Wentworth.
CANANDAIGUA, N. Y.—C. J. Purdy.
CANAJOHARIE, N. Y.—C. S. Fargo.
CARBONDALE, PA.—J. W. C. Aitken.
CHARLOTTE, N. C.—H. Thompson.
CHELSEA, MASS.—E. A. Chapel, George W. Moses and W. G. Peck.
COLORADO SPRINGS, COLO.—E. E. Wade.
COLUMBUS, O.—A. W. Field and Adolf Theobald.
CONCORD, N. H.—George B. Lander.
CUYAHOGA FALLS, O.—C. L. Babcock.
CAMDEN, N. J.—E. A. Armstrong, C. C. Burleigh and J. J. Burleigh.
CHICAGO, ILL.—Forée Bain, W. F. Collins, Henry Cribben, W. J. Ferris, J. Holt Gates, C. E. Gregory, H. K. Golsin, R. J. Randolph, C. J. Reilly, J. R. Wiley, C. H. Wilmerding and James Wolff.
CINCINNATI, O.—John I. Beggs, W. L. Bradshaw, J. A. Cabot, Thos. J. Creaghead, J. S. Nowotny and W. M. Venable.
CLEVELAND, O.—V. Browning, W. B. Cleveland, H. J. Dowds, M. M. Hayden, G. M. Hoag, S. K. Johns, S. C. D. Johns, B. T. Miles, L. H. Rogers, W. S. Rogers, Charles W. Wason and Bailey Whipple.
HARTFORD, CONN.—C. E. Dustin, G. W. Hart, E. B. Hatch, C. E. Newton and A. H. Pease.
MILWAUKEE, WIS.—J. Goldschmidt, W. F. Hyde, J. R. Mercein and A. Smith.
MONTREAL, CAN.—Prof. H. T. Bovey, W. H. Browne, F. R. Redpath, R. A. Ross and G. W. Sadler.
NEW BEDFORD, MASS.—C. S. Mendell, Charles R. Price, George R. Stetson and A. P. Smith.
PHILADELPHIA, PA.—James G. Biddle, C. A. Bragg, C. M. Corpening, J. T. Cowling, H. B. Cutter, F. W. Darlington, A. J. De Camp, W. E. Harrington, George W. G. Holman, A. H. James, W. O. Knudson, C. W. Dazar, H. J. Manloux, A. H. Manwaring, John Mustard, S. L. Nicholson, A. B. Poulson, O. D. Pierce, J. P. Richardson, Charles J. Russell, T. Carpenter Smith, E. Ward Wilkins, C. M. Wilkins, E. T. Wilkinson and E. G. Willyoung.
PITTSBURG, PA.—B. H. Blood, J. S. Crider, E. H. Heinrichs, A. H. Mustard, Robert J. McGoumel, J. W. Marsh, C. F. Scott and H. E. Webb.
PITTSFIELD, MASS.—J. H. Finley, W. R. Gardener, Henry Hine and J. F. Kelly.
PROVIDENCE, R. I.—J. F. Blauvelt, Eugene F. Phillips, Frank N. Phillips and C. R. Remington.
ROCHESTER, N. Y.—Charles F. Barnes, Fred. Fish, F. Kirk Knowlton, J. A. Olmstead, J. E. Putnam and George A. Redman.
SCHENECTADY, N. Y.—J. P. Feeton, S. D. Greene, J. R. Lovejoy, E. W. Rice and C. P. Steinmetz.
ST. LOUIS, MO.—E. H. ABADIE, Edwin S. Pillsbury, J. H. Rhotehamel, E. G. Spencer, J. A. J. Shultz, H. A. Wagner and Sylvester Watts.
UTICA, N. Y.—W. C. Ballda, William F. Bossert, W. E. Lewis, J. F. Mann, D. McAfee, T. R. Proctor and H. P. Roberts.
WASHINGTON, D. C.—H. G. Balkam, P. A. Draper, J. Kennedy, F. D. Royce, F. W. Royce and A. A. Thomas.
WORCESTER, MASS.—Charles W. Bassett, John P. Coghlin, W. H. Coughlin and H. H. Fairbanks.
DAYTON, O.—H. W. Fullerton.
DERBY, CONN.—R. E. Nugent.
DETROIT, MICH.—C. H. Matthews, C. A. Ducharme and Alex. Dow.

WARREN, O.—W. D. Packard.
WATERTOWN, N. Y.— R. E. Cahill.

NOTABILITIES AT THE EXPOSITION.

There can be no question of the fact that the Electrical Exposition has "caught the town." Fashionable visitors are there in throngs, and notabilities can be counted by the dozen every night. Among those present last week were George Westinghouse, Jr., T. A. Edison, Cornelius Vanderbilt, Chauncey M. Depew, Charles Delmonico. The meeting between Prof. Bell and Mr. Edison was very interesting, and took place in the private reception room fitted up for the fluoroscope exhibit. Prof. Bell was escorted through the Exposition by Mr. Herbert Laws Webb, and took much pleasure in listening to the roar of Niagara at the Niagara model. The pair of receivers used by him were immediately labeled and put within the model case.

THE INCLOSED ARC is emphatically one of the most noteworthy features of the exposition. It burns everywhere with brilliant success and silence.

THE CROCKER-WHEELER ELECTRIC CO.'S "AT HOME."

MAY 7 will long be remembered as a red letter day in the history of Ampere, N. J. On the evening of that day no less than 4,000 visitors, who came by train, boat, bicycle and on foot, invaded the usually quiet village for the special purpose of inspecting the new works of the Crocker-Wheeler Electric Company, and they were well rewarded for their trouble. The two regular trains from New York brought about 200 and 400 people, respectively, and the special train in charge of Dr. Wheeler and Superintendent Griffith, of the works, which arived at 8:45, brought 580 visitors from New York in ten cars. The crush was so great, indeed, that it was necessary to hold the Christopher street ferryboat some minutes in order to let the party pass through the gates.

There was no mistaking the place by the stranger, for a huge sign "Ampere," in incandescent lamps, with letters six feet high, blazed forth on the lawn facing the station. One hundred steps brought the visitor into the works, where Messrs. Crocker, Wheeler, Dunn, Jeffrey, Lufkin, and their assistants, welcomed the guests.

Thousands of incandescent lamps illuminated the great works, in which every machine tool was at work producing a particular part of the dynamos and motors, which are the specialties of the company. Beginning at one end of the building, which is 550 feet long, the visitors saw the punching machines and shears at work cutting out the special shapes of armature plates. When put together and mounted on their spiders and shafts they are passed along the shops to receive the wires; joining their frames and field magnets a little farther along the dynamo takes its complete shape at the testing department, after which it is boxed and ready for forwarding by a branch of the Delaware, Lackawanna and Western Railroad, whose tracks enter the building.

The principal engineering feature of these works is the employment of the electrical power transmission system, each tool being operated by its own motor fixed in the frame or attached to the bedplates, thereby economizing power to an enormous extent and also giving greater liberty in arranging the position of tools, as they are independent of locality. This latter feature was illustrated in a striking manner by one of the large lathes weighing about four tons, which was slung in the traveling electric crane, and kept passing up and down the shop above the visitors' heads while it was turning a 5-inch steel shaft 10 feet long, the shaving from the tool coiling down among the guests, who broke off yards of it as souvenirs. The cut which was being taken by this tool was half an inch deep.

The result of the electric power system is that all power used in connection with a machine stops when the machine is out of use, there being no long heavy lines of shafting to be kept in motion whether machines are working or not, as in the old style shops. It may not be generally known that on the average 70 per cent. of the indicated power of shop engines is absorbed by shafting without a particle of work being done by the tools. When this is compared to the loss of 10 to 12 per cent. in the motors in the electric power system the enormous advantage of the latter becomes apparent. In this connection an interesting photo was exhibited illustrating a lathe at work under a canvas tent; this photo carries with it the following legend: Thirteen months ago the company's plant was destroyed by fire and a large lathe escaped serious damage. It was moved outside the ruins at once and connected to wires, and was at work again in a few days, a tent was erected over it and it continued its work there for two months. It is estimated that if the company used shafting and belts instead of electrical power, 4,000 feet of 3½-inch steel shaft would be required for main shafting alone, with 400 pedestals, and that 125 horse-power would be required to do their work. Their average of power used for tools alone (not including lighting) is 25 horse-power, under their present system. When it is necessary to keep only a few tools at work, say at night a small donkey engine and dynamo supply the power, thereby further economizing and avoiding the loss incidental to running their main engine with the small load.

The power house is distant about 50 feet from the shop, and is a separate building connected, however, by a cable-tunnel 7 feet high and 3 feet wide, and well lighted, through which the cables are laid.

The floor of the shop is a special feature of the place, being made of cement of such a depth that no foundations are required under the machines. The heaviest machines can be placed anywhere on this floor. Ducts in which the motor wires are laid are built in the floor and radiate from the gallery pillars in which the leads are placed.

The works as a whole are perhaps the most perfect example in the country of what can be done with electric power transmission. The freedom of the shop from belts is one of the things that impress the visitor at every turn, as one naturally has to keep his eyes about him in the old style shops to avoid danger, while here there is no danger to guard against. It was a common sight to see ladies gathered around a fast moving machine on all sides with perfect safety, a thing not possible where belts are running.

At 9:45 the fire signal was given, so that the visitors might see how perfect are the precautions taken against fire. The workmen detailed for this duty left their machines at the signal, and in thirty seconds had four streams of water playing on the building. This was very quick work. The time required, however, on ordinary occasions when they are drilled, is sixty seconds.

During the evening Prof. Vorse's string orchestra of ten pieces rendered many selections in the office building, where 1,756 of the guests left their autographs in the visitors' book, the pages of which had been separated and put on different desks to facilitate the work.

The evening will long be remembered by Messrs. Crocker and Wheeler's many friends as being a most highly enjoyable and instructive occasion.

Among the guests present were the following:

Joseph T. Brown, vice-president Knickerbocker Trust Company, New York; Mr. and Mrs. H. Ward Leonard, East Orange; Mrs. Richard Arnold, Dr. and Mrs. George R. Lockwood, F. J. Griffith, superintendent Delaware, Lackawanna and Western Railroad; Miss Wilkinson, Surrogate and Mrs. John H. V. Arnold, Dr. Charles E. Emery, J. Soutter Potter, D. Walter Gibson, Prof. F. B. Crocker, of Columbia University, New York City; Mr. and Mrs. William B. Nivin, Miss Spratt, Mr. and Mrs. F. L. Eberhard, J. George Naphey, superintendent Delaware, Lackawanna and Western Railroad; J. H. Haynes, postmaster of Newark, N. J.; George D. Haynes, assistant postmaster, Newark, N. J.; F. A. Pickernell, of the American Telephone and Telegraph Company; Frederick Reckenzaun, Henry H. Holly, Jr., Mr. and Mrs. Andrew Prentiss, Dr. Charles A. Doremus, College of the City of New York, New York; W. H. Freedman, Columbia University, New York; Charles T. Rittenhouse, Chauncey Griswold, Mr. and Mrs. George R. Howe, Mr. and Mrs. A. A. Carey, New York; Prof. H. Bovey, of McGill University, Montreal, Can.; Fred F. Smith, Nelson W. Perry, J. George Hahne, Newark; John Lorillard Arden, Gramercy Park, New York; Edwin C. Alden, A. D. Baldwin, Caleb C. Green, S. C. Pullman, William Pullman, George K. Garvin, C. R. Pratt, F. M. Unstiedt, Lasavia, Jamaica, W. I.; Mr. and Mrs. Cleveland Dunn, Harris A. Dunn, Edith Fortmeyer, Judge J. Frank Fort and Miss Fort, Harding Benedict, W. T. Bowman, building inspector, East Orange, N. J.; Prof. Hovey, Irving H. Tift, Henry H. Hall, T. F. Nivin, W. Frazar Gibson, E. J. Condit, J. W. Lieb, Jr., Edison Electric Illuminating Company, New York; Dr. and Mrs. Pinkham, H. E. Shaw, Frederick E. Brown, of the New York City Board of Electrical Control; Prof. A. D. F. Hamley, Columbia University; Hon. William A. Brown, New York City; B. F. Stangland, William Jeffreys, Sr.; Stephen J. Burk, Barton Cruikshank, Mr. and the Misses Balven, Prof. W. A. Anthony, Mrs. Creagh, George F. Sever, Mr. V. Chattilon, Miss Carpenter, E. G. Snow, Reginald Arnold, N. Lester Mullen, Phillipo Torchio, Mr. and Mrs. Albert Spies and Miss Spies, L. V. Mahan, Miss Bartow, John K. Gore, Mrs. Annie P. Knowlton, D. L. Davis, C. A. Hunger, H. H. Hunger, H. R. Halsted, Abram Hyatt, J. A. Machado, Herbert W. York, engineer, United Electric Light and Power Company, New York, and Mrs. York; H. B. Walker, "German Herald," Orange, N. J.; B. J. Hamilton, Edwin J. Gillian, Thomas H. Bolmer, H. D. W. Dobbs, W. H. Ballentine, John R. Black, James Sleighter, Mr. and Mrs. E. D. Tucker, Mr. and Mrs. J. S. Hillman, Miss Hillman, C. R. Poillon, H. M. Davis, A. W. Law, Mr. and Mrs. Jos. T. Brown, Hon. and Mrs. Sydney M. Ogden, R. Varley, Jr., W. H. Demarest, Lewis C. Harker, Mrs. and Miss Colwell, Mr. and Mrs. William H. Young, R. M. Henning, Mr. and Mrs. M. H. Whiting, Mr. and Mrs. P. H. Brandt, Prof. R. Ogden Doremus, College of the City of New York; Mrs. and Miss Estelle Doremus, Maxwell M. Meyer, F. O. Runyon, the Misses Leverich, Mr. and Mrs. A. H. Palmer, George S. Hulburt, Mr. and Mrs. W. H. Force, Mr. and Mrs. W. M. Aikman, Mr. and Mrs. Mandelick, H. S. Buttenheim, H. H. Van Rensselaer, Mr. and Mrs. A. K. Sloan, Robert Christie, Jr., Miss Vanderveer, Prof. Webb, Stevens Institute of Technology, Hoboken, N. J.; C. O. Mailloux, New York; Charles Frederick Walker, Rev. M. J. Cramer, D. D.; C. Howard Parmley and wife, Frederick R. Remer, Mr. and Mrs. Ernest Napier, Miss Lillian Napier, Mr. and Mrs. C. W. Potter, Mr. A. D. Chambers, treasurer, Delaware, Lackawanna and Western Railroad, East Orange, N. J.; Alden Freeman, Albert R. Martin, Mr. and Mrs. Frank J. French, Colonel and Mrs. A. H. Ryan, J. Grant Cramer, Mr. and Mrs. F. W. Moore, Dr. J. F. McBride, W. E. Thatcher, A. C. Doane, C. F.

Herring, Mr. and Mrs. A. S. Sherwood, Mr. and Mrs. C. T. Hughes, A. Ward Brigham and son, Spencer S. Marsh, Charles Joy, Mr. and Mrs. Lincoln Righter, W. S. Robinson, M. D.; William H. Baker, William F. Poucher, William E. Ashmall, Mr. and Mrs. E. A. Spooner, William J. Campbell, M. T. Rockwell, Mr. and Mrs. Charles H. Sleight, George O. Leavitt, H. P. Backus, George Dorer, Mr. and Mrs. W. L. Merrick, Mr. and Mrs. C. A. Westervelt, A. P. Boller, G. H. Gedney, D. M. Meeker, E. R. Crippen, O. S. Young, H. R. Halsey, L. W. Woolley, E. von Diezelski, A. D. Palmer, Mr. and Mrs. Fred D. Ward, W. H. Selkirk, Samuel Bailey, J. F. Cross, S. W. Ougheltree, James Leitch, C. S. French, C. C. Jacobus, George W. Carnrick, Mr. and Mrs. Montgomery Lindsay, C. S. Stockton, George C. Miller, John Winfield Scott, Mr. Auerbacher, Ellis A. Apgar, H. D. Miller, John Remer, Lewis McCould, Edward E. Bruen, Dr. and Mrs. R. M. Sanger, Mrs. Fannie C. Jeffrey, Miss Lockwood, F. H. Kingsbury, Mr. and Mrs. William E. Davis, and H. Eber Pratt.

CONVENTION NOTES.

THE NEW YORK INSULATED WIRE CO. made things very interesting for many of the visitors to the convention, in their comfortable parlors on the first floor of the Murray Hill Hotel. There Messrs. Gallagher and Kelly, assisted ably by Mr. Wolff, of Chicago, held court for four days, and dispensed their hospitality in their usual open-handed fashion. Their parlors, in the evening especially, attracted large numbers, and a chairman for the evening being duly elected, all proceeded to enjoy life, with many a good story pertaining to the wonders of the electric fluid.

COLONEL BOOKER, of St. Louis, made his headquarters at the Imperial, and succeeded in interesting a great many in the all-important question of the best carbon to use. Dame Rumor says that "he got some orders, too."

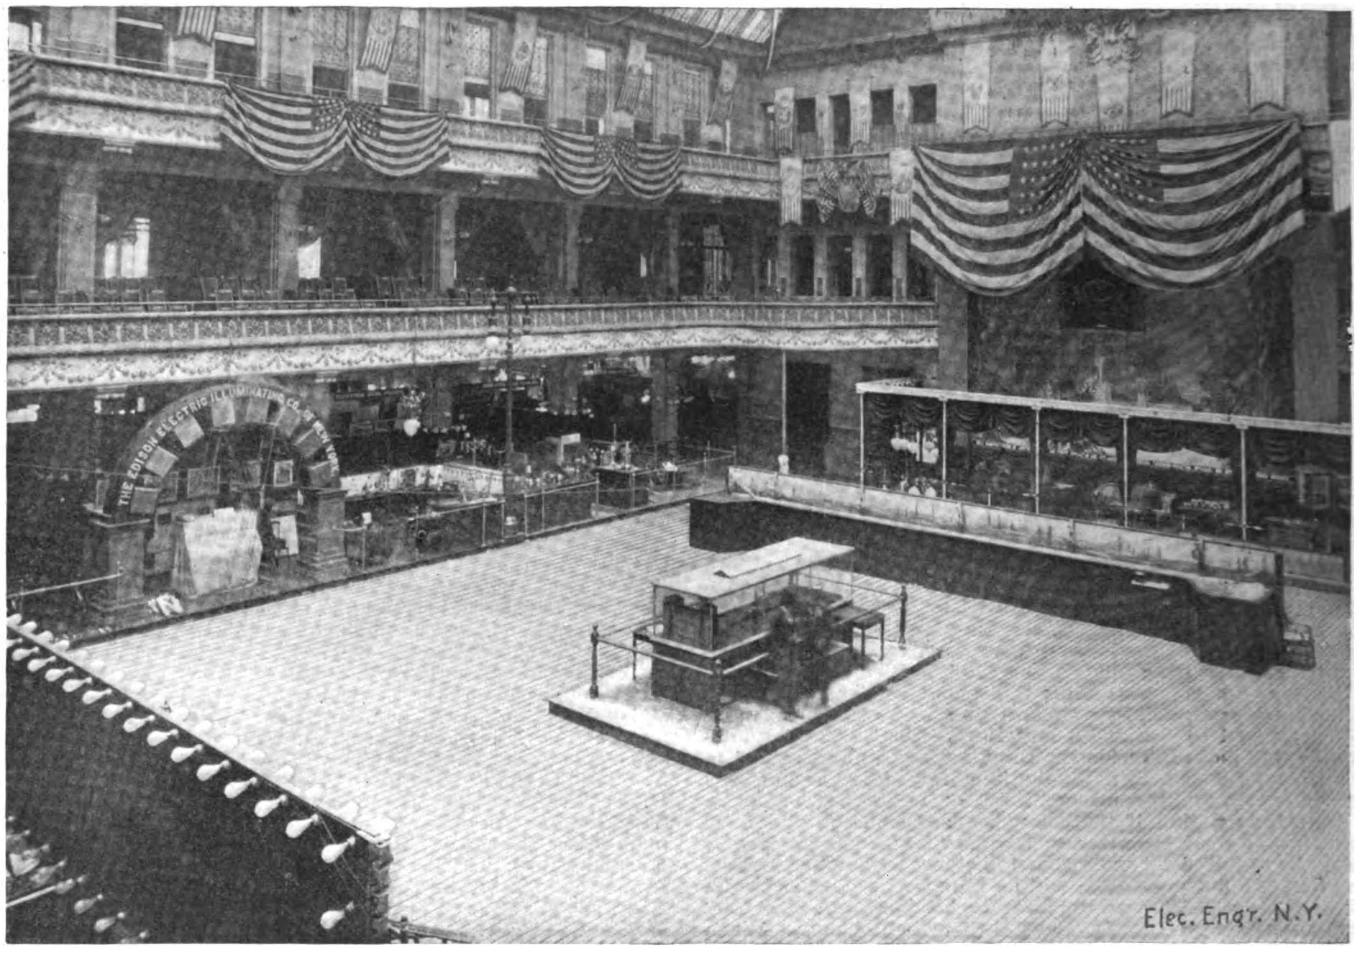
THE AMERICAN CIRCULAR LOOM CO., of Boston, had a handsome suite of rooms on the first floor of the Murray Hill Hotel, where they entertained large crowds of visitors during the life of the convention. The rooms were in charge of Messrs. H. H. Brooks, A. T. Clark, C. D. Doubleday, J. Wilson and others, who were kept extremely busy dispensing the hospitalities for which their company have established an enviable reputation. It may interest our readers to know that Mr. Brooks has permanently left Chicago, where he has resided during the past winter, and will once more take up his headquarters in the East.

PROF. H. G. BOVEY, of McGill University, and his brother-in-law, Mr. Frank Redpath, were among the notable attendants at the convention and exposition. They were both greatly pleased at what they saw and at their reception by New York electrical friends. Among the entertainments was a luncheon given at the Waldorf by Mr. C. R. Huntley, the party including also Messrs. F. Nicholls, C. W. Price, J. Seely, T. C. Martin, G. Urban and J. I. Ayer.

THE LEWIS TOOL WORKS exhibit a very fine line of adjustable jaw vises. They also show a new bicycle vise which holds the frame of a bicycle very securely.

THE CROUSE-TREMAINE CARBON CO. have arranged a very attractive display of their carbon specialties. They exhibit raw material of carbon used in the manufacture of their products, which is of a very high grade. A xylophone, if one may call it by that name, made of carbon pencils, illustrates the density and durability of the material and the curved carbons employed for special arc lamps show the great strides which have been made in the manufacture of electric light carbons. This interesting exhibit, decorated with flags and bunting, is in charge of Messrs. J. B. Crouse, H. A. Tremaine and H. S. Hart.

THE GOLDEN KEY with which the exposition was opened was loaned by Gen. E. S. Greeley for the occasion. The General has added to the base in metal letters, "New York, 1896," to correspond with "Chicago, 1893," on another face. The key is jealously guarded.



View of Main Hall of the Electrical Exposition, New York, from North East Corner.

EXHIBITION NOTES.

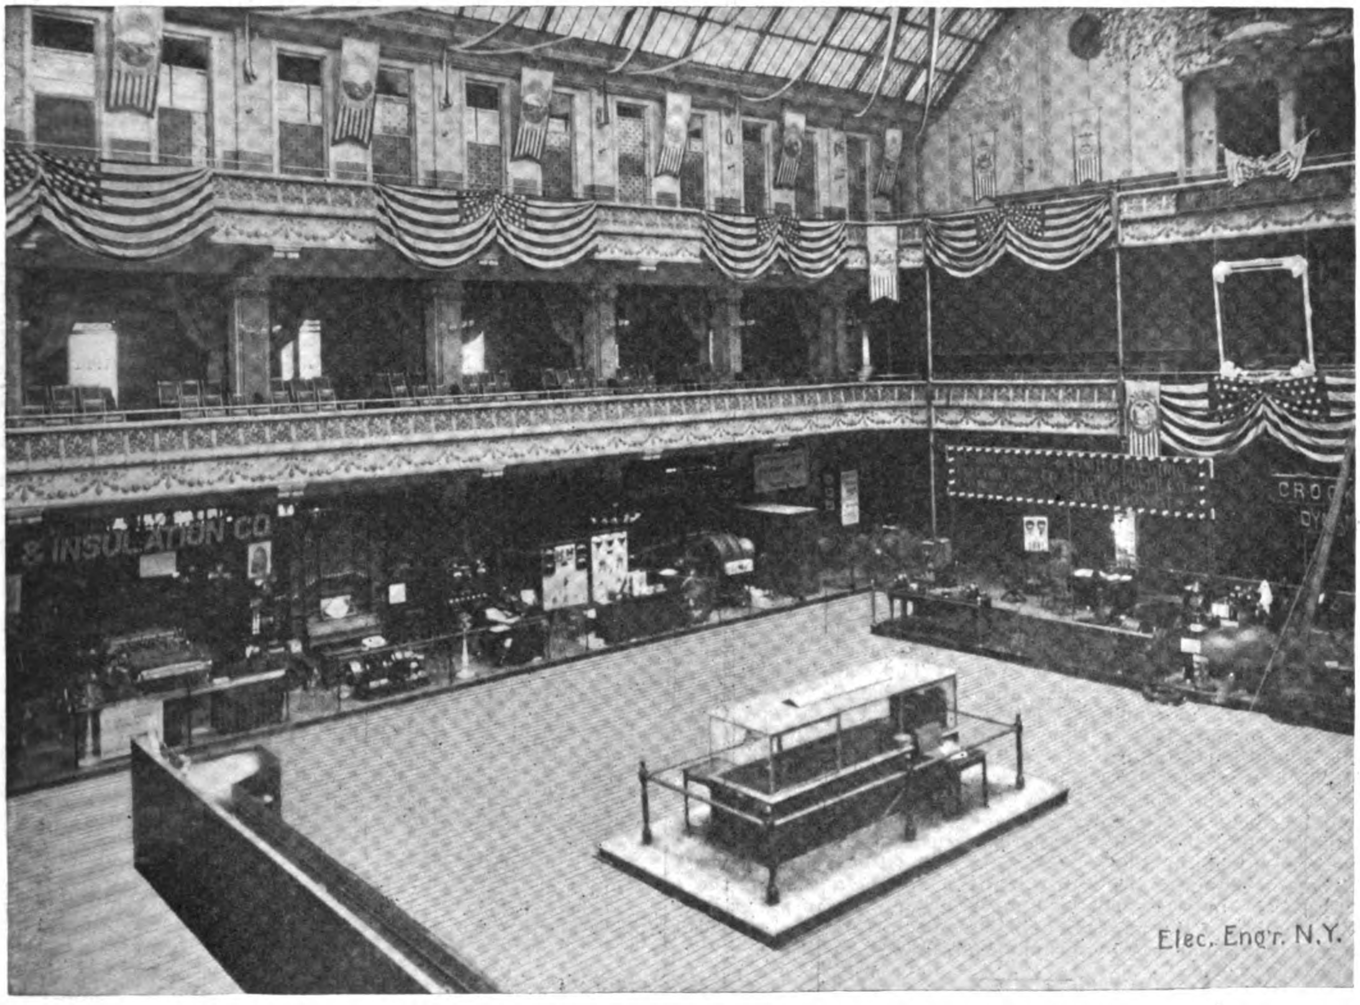
THE EXPOSITION MAIN HALL.

THE accompanying engravings represent two views of the main hall of the Electrical Exposition Building, which will give a good idea of the character and extent of the exhibits. The view taken from the northeast corner of the hall shows, at the left, the exhibit of the Edison Electric Illuminating Company, of New York, in which that enterprising company demonstrates in a practical way the numberless uses to which current can be put in the household, as an illuminant, a source of power and heat. It also shows the uses to which current can be put for public lighting, and for the operation of machinery, such as printing presses and countless other devices. At the right is the exhibit of the General Electric Company, which is more fully described elsewhere in this issue.

The long stand immediately in front of the General Electric Company's exhibit represents the model of the Erie Canal with a canal boat hauled by electricity on the Lamb system of electric haulage.

The center of the floor contains the model of the great Niagara power house, which is operated by current sent over the Western Union wires from Niagara. On the table beside it are placed a number of telephone receivers, which enable the public to hear the roar of Niagara Falls, transmitted over the wires of the American Telephone and Telegraph (Long Distance) Company.

The view taken from the southwest corner shows at the extreme left a part of the exhibit of the Interior Conduit and Insulation Company, including a printing press and an organ operated by Lundell motors. Beside it is the exhibit of the Stanley Electric Manufacturing Company, containing the large S. K. C. alternator. At the east end, in the gallery, will be seen the frame of Moore vacuum tubes, which encircled and illuminated Governor Morton as he touched the key and declared the exposition open. Below the frame are the exhibits of the Westinghouse Company and a part of the Crocker-Wheeler Electric Company's.



VIEW OF MAIN HALL OF THE ELECTRICAL EXPOSITION, NEW YORK, FROM SOUTH-WEST CORNER.

WESTINGHOUSE ELECTRIC & MANUFACTURING CO.

Immediately upon entering the main door of the exposition is noticed the space occupied by the Westinghouse Electric and Manufacturing Company. There is a beautiful red and gold sign suspended above the exhibit, but even without that it could be easily recognized that this is the place where the Westinghouse people are holding forth, inasmuch as Tesla motors and other Westinghouse apparatus were plentifully in evidence. Mr. A. C. Zimmerman, of the New York office, and Mr. M. MacLaren, from the Pittsburg factory, are in charge of the exhibit. Mr. MacLaren has been especially detailed to look out for the power transmission from the Niagara Falls power current. The company has on exhibiton a lamp board in the center of which is seen the Shallenberger electric meter. The case of this meter is removed, and in this way the actual operation of this well-known device is plainly demonstrated, and attracts a great deal of attention. Another interesting feature is an illustration given of the principle of induction, which is demonstrated with an induction coil. The company's exhibit is lighted up with the well-known Sawyer-Man incandescent lamp. On the floor stands a 20 horse-power Tesla motor, driving a 20 horse-power D. C. generator. In addition to that, there were several other Tesla two-phase motors, single-phase motors and a number of converters. Mr. C. F. Scott, the electrician of the company; Mr. Allen, from the Philadelphia office, and Mr. E. H. Heinrichs, are in charge.

THE EXHIBIT of the Akron Insulator and Marble Company, of Ohio, at the Electrical Exposition, is in charge of Mr. Harry G. Osborne, of Chicago.

THE POSTAL WIRES ON OPENING NIGHT.

The Postal-Telegraph Company have received the following letter from the officers of the National Electric Light Association and the management of the exposition:

May 7, 1896.

Postal-Telegraph Cable Company, 253 Broadway, New York:

Gentlemen—In behalf of the management of the National Electrical Exposition, I beg to thank you for your courtesy and valuable aid in connection with the arrangement for firing guns simultaneously at San Francisco, St. Paul, New Orleans and Augusta, Me., announcing the opening of the exposition at the Grand Central Palace, New York, on Monday evening, May 4, 1896.

The circuit, which was composed throughout of the copper wires belonging to your company, was the longest circuit ever established for the purpose of firing cannon simultaneously at widely separated points, and the use of current derived from the power plant at Niagara to energize that part of the circuit between Buffalo and New York was the first time that such current was used for telegraphic purposes.

Immediately after Governor Morton had closed the circuit (by means of the gold telegraph key, which had been previously used only to start the machinery of the World's Fair at Chicago) messages were received from all of the above-named cities, announcing that the guns had been fired electrically by his closing of the circuit and without other human intervention, and telegrams of congratulation to the Governor from the Mayors of the points named followed within a remarkably brief space of time.

Your company is to be congratulated. not only upon the possession of wire facilities which enable you to accomplish this remarkable feat of long-distance telegraphy, but also upon the thorough organization and hearty co-operation of your employés throughout the country, without which it could not have been successfully accomplished.

Thanking you again for your courtesy and aid, we are,

Yours truly,
(Signed) C. H. WILMERDING,
President, National Electric Light Association.
(Signed) HARRISON J. SMITH,
President, Exposition Company.
(Signed) GEORGE F. PORTER,
Secretary.
(Signed) F. W. HAWLEY,
Chairman, Reception Committee.

A MESSAGE AROUND THE WORLD FROM THE EXPOSITION.

Great preparations are being made for the sending of a message around the world from the National Electrical Exposition, the text of which is to be prepared by Mr. Chauncey M. Depew, who is also to deliver an oration on the place and progress of electricity in modern life. The occasion will be Saturday, May 16, at 8 p. m. Mr. A. B. Chandler, president of the Postal-Telegraph and Cable Company, is to send the message for Mr. Depew from a balcony in the main hall of the Exposition Building. Across the hall, in another balcony, Mr. Edison will receive the message for Mr. E. D. Adams, the president of the Niagara Falls Power Company. The circuit will be about 28,500 miles in length, the Commercial Cable Company and the Postal wires being used for the American sections outside of South America, which will be reached via Lisbon on the message's return trip. A huge map showing the path of the message will be hung from one of the galleries. The starting of the message and its return are to be signalled in a very original way by means of novel lighting effects.

THE EXPOSITION CATALOGUE.

Owing to the great rush of exhibitors at the last minute the Official Catalogue of the National Electrical Exposition was delayed in its appearance, but was in good time after all, and was heartily welcomed. It a handsome book, well arranged, and clearly printed on good paper, useful not only as a guide, but as a souvenir. It is about 200 pages, has an ornamental cover in good taste, and sells for a quarter. The printer, Mr. J. E. Phelps, was assisted by Messrs. Stump and Rouse in its compilation.

THE EXCELSIOR ELECTRIC CO. exhibit their new type of arc machine for central station work. They have in operation a 125-light arc machine driven by a 44-horse-power multipolar motor; the arc generator supplies the hall with current. They also show an equalizer which splits a 250-volt current into halves; and a number of new style arc lamps and motors. The booth is gaily decorated and in charge of Mr. H. H. Hochhausen.

MISCELLANEOUS EXHIBITS—I.

THE BURRY PRINTING TELEGRAPH SYSTEM.

THE Patent Office exhibit in the Historical and Loan exhibition at the Electrical Exposition contains a number of telegraph models of note, but the only live telegraph exhibit in the whole exposition is the printing telegraph of Mr. John Burry, of New York. A couple of tickers are mounted on

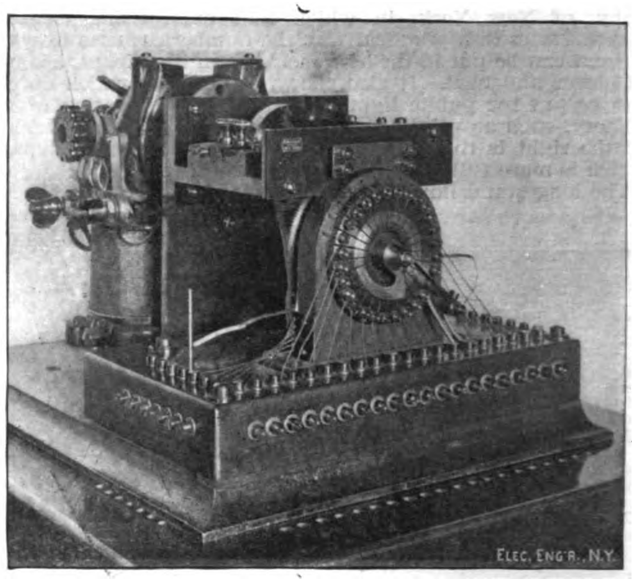


FIG. 1.—THE BURRY PRINTING TELEGRAPH TRANSMITTER.

stands, and the tapes are eagerly scanned by the lovers of baseball, and the sporting public generally.

Close beside the ticker is the transmitter used at the central office. This system has been adopted by the Stock Quotation Telegraph Company, in New York, and is in successful operation in all the large cities of the United States and Canada.

The principal instruments in the Burry system are the transmitter, Fig. 1; the ticker, or receiving instrument, Fig. 2; and the relay and keyboard, Fig. 3. Fig. 4 is a section of the switchboard in the New York office of the Stock Quotation Telegraph Company.

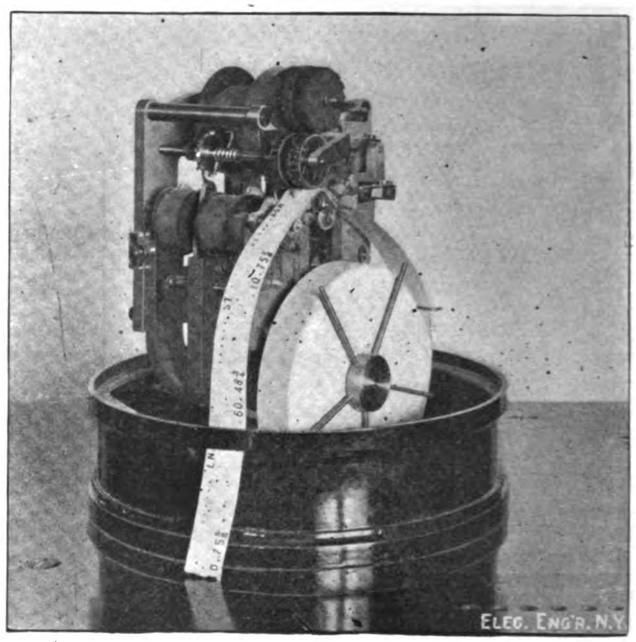

FIG. 2.—THE BURRY TICKER INSTRUMENT.

The transmitter is the apparatus which automatically controls the polarity, strength, duration and number of electrical

impulses required in the manipulation of the tickers. Its principal parts are shown in Figs. 5 and 6. Here A is an electric motor; B, a friction clutch; C, a circuit-wheel; D, a magnetic clutch; E, a gear; F, a sunflower, and A, a trailer.

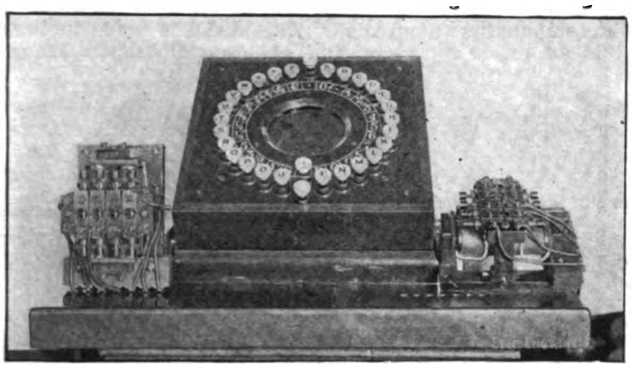

FIG. 3.—THE BURRY RELAY AND KEYBOARD.

This small, simple machine has the capacity to control simultaneously all the various functions of more than 2,000 tickers.

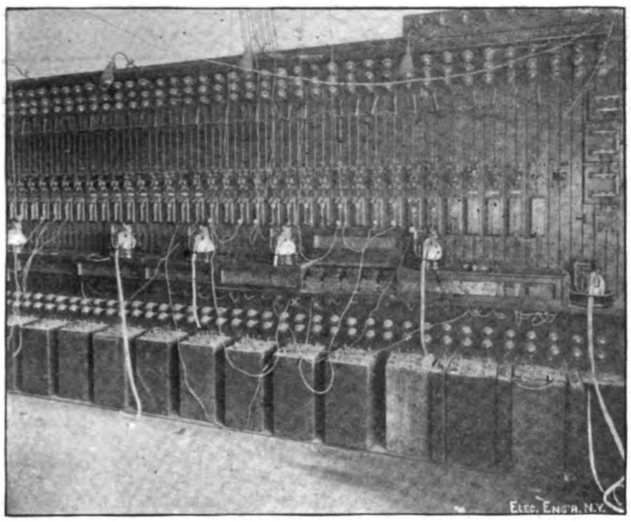

FIG. 4.—SECTION OF SWITCHBOARD IN NEW YORK OFFICE OF STOCK QUOTATION TELEGRAPH CO.

The keyboard is an automatic arrangement to control the movements of the transmitter. It is operated like a typewriter. The relay, with its resilient armature, I, Fig. 7, and stat; X and W, condensers to prevent sparking; I, armatures, and E, are the relay magnets.

By the rotation of the circuit wheel, C, the magnets, E, are alternately charged and discharged, which causes the armatures, I, to vibrate and connect + or — currents to line, as may be seen in Fig. 8.

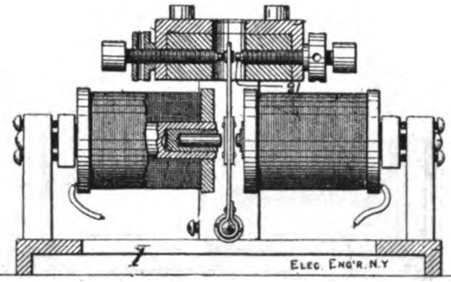

FIG. 7.—THE BURRY RELAY.

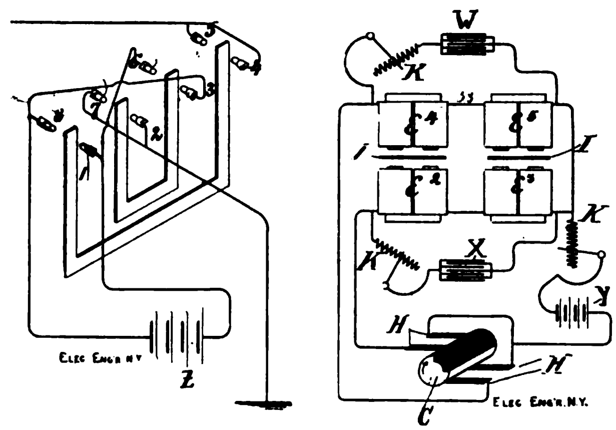
The ticker is small, neat in its appearance, requires only one line wire, prints two lines of type, and is provided with an automatic spring winding attachment.

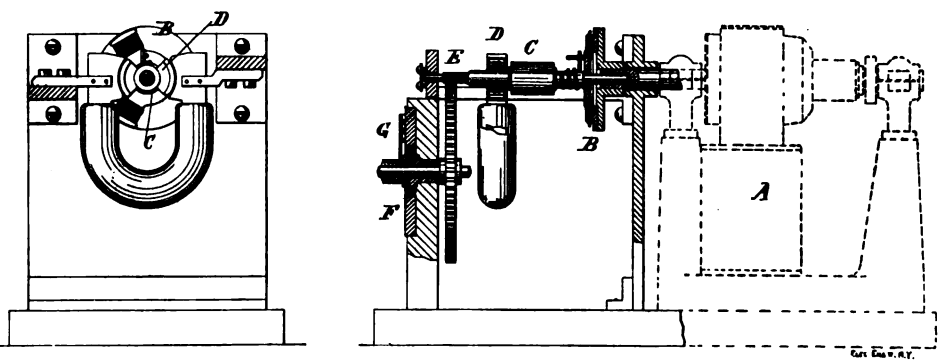
It may be of interest to note in this connection that Mr. Burry recommended the use of storage batteries for ticker service as far back as 1892, against the advice of all electrical experts. In spite of all the opposition to the scheme a battery company was induced to put in a plant for a six-months' trial. It proved to be a revelation in regard to quality of current, labor saving and general economy.



FIGS. 8 AND 9.—RELAY AND DIAGRAM OF CONNECTIONS.

A motor generator keeps up the potential of the battery, which is too small for full load during working hours, but the regular charge is delivered from the mains of the Edison Illuminating Company at night.

Mr. Paul Hoenack builds the transmitters and relays, and Mr. Oscar F. Ehrle the tickers and appurtenances of the Burry system.



FIGS. 5 AND 6.—THE BURRY TRANSMITTER—TRANSVERSE AND LONGITUDINAL SECTIONS.

number of contacts in series 1, 2, 3, 4, 5, 6, 7, 8, Fig. 8, insures a very perfect alternating current, without sparking.

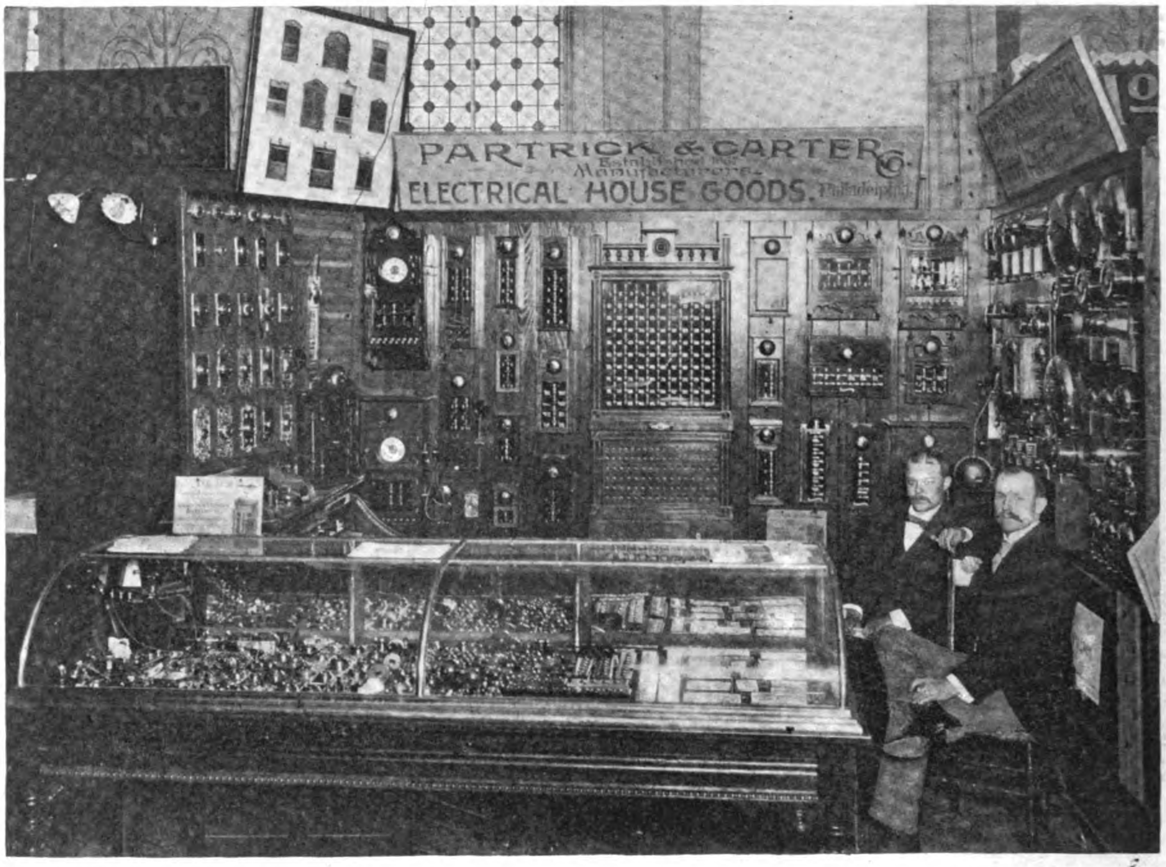
Fig. 9 is a diagrammatic view of the electrical connection of the transmitter and two relays for two circuits. Y is the battery; C, the circuit wheel; H, the brushes; K, an adjustable rheo-

---

THE VACUUM OIL CO. exhibit an assortment of dynamo and engine oil. Mr. E. A. Record is in charge of the exhibit.

THE PARTRICK & CARTER EXHIBIT.

PERHAPS the most complete display of electrical supplies for hotel and general house purposes made at the exposition is that of Messrs. Partrick & Carter, of Philadelphia. To merely mention, without describing, the articles with which the exhibit fairly bristles, would occupy columns, but our readers will better appreciate the extent and character of the display by a glance at the accompanying engraving made from a photo taken on the spot.



THE PARTRICK & CARTER CO.'S EXHIBIT AT THE ELECTRICAL EXPOSITION, NEW YORK.

The exhibit is in charge of Mr. T. L. Townsend, who never tires of answering the calls which come over the Simplex-Interior Telephone system, for which the company manufactures hotel office boards, one of which forms a prominent feature on the rear wall of the exhibit.

THE EDISON EXHIBIT OF ROENTGEN RAYS AND FLUOROSCOPE.

Mr. Edison has very generously placed at the disposal of the exposition a part of his laboratory staff and some of his apparatus for making an exhibit of Röntgen effects. A special room, with the appropriate annexes and ante-chambers, has been fitted up under the expert guidance of Mr. Luther Stieringer, with somber black drapings and dull red lamps, so that the public can get the best effect. A fluorescent screen, about 18 by 22 inches, is arranged on a large platform in such a way that two persons can come forward and see their own anatomy, etc., in a few seconds and then make room for somebody else. The whole plan has been most ingeniously worked out and has received Mr. Edison's personal attention and approval, hours of uninterrupted work having been given by him to it. The exhibition will be given by Mr. Edison's staff under the supervision of Mr. Max Osterberg, who has the adjoining laboratory exhibit. The scheme is so laid out that several thousand people can pass through the dark hall in a single evening.

THE SIEMENS & HALSKE CO. exhibit consists of a 100 kilowatt multipolar generator driven by a Ball & Wood engine direct connected. The pole pieces are within the armature, the peripheral conductors of which are bare and against which the brushes bear. The combination is a very neat one.

A HANDSOME SOUVENIR.

THE Wagner Electric Manufacturing Company, of St. Louis, during the convention presented their friends with very handsome souvenirs in the shape of an ink well, as shown in the accompanying illustration. The model is made in brass, and is an exact representation of the well-known Wagner transformer, being made to scale in the factory of the Wagner Company in St. Louis. Every central station manager interested in transformers who was not fortunate enough to procure one should write the Wagner Company without delay and get one for his desk, as there are only a few of them left.

THE WAGNER TRANSFORMER INK WELL.

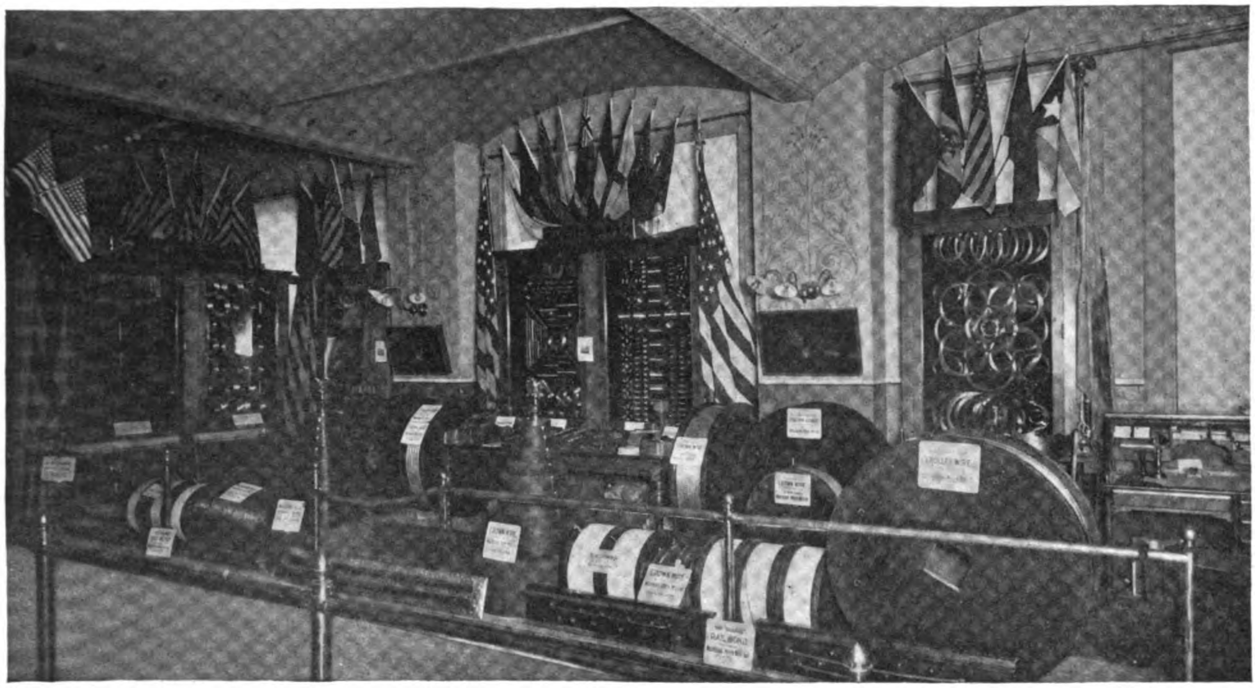
MR. A. O. SCHOONMAKER'S exhibit consists of a full line of mica segments, washes and discs. Mr. Dunning is in charge of the booth.

THE WASHBURN & MOEN MANUFACTURING CO.'S EXHIBIT.

ONE of the most attractive and interesting displays at the exposition is found in spaces 14-17, section A, main floor, and in this beautifully decorated inclosure the Washburn & Moen Manufacturing Company exhibit their well-known cables and wires.

Besides a general exhibit of all kinds of wires for lighting and railway purposes, the glass cases which line the walls contain samples of bare, high grade copper wire. Among these is a copper wire .0025 inch in diameter; 10¼ miles of it only weigh a trifle over one pound. Their well-known "Crown" wire a reel of which, lead covered for underground purposes, is also shown.

Besides this they have on exhibition a section of the main feeder wires supplying current in the exposition building, and having cross section of 2,000,000 c. m. A still larger one, 2,790,000 c. m. in section is also manufactured and is said to be the largest single electrical conductor in use in this country.



THE WASHBURN & MOEN MANUFACTURING CO.'S EXHIBIT AT THE ELECTRICAL EXPOSITION, NEW YORK.

One case contains a large number of steel models illustrating the wires of irregular shapes made by the company.

Besides these they show electric railway materials, their new 8-section trolley wire, and a reel of 500,000 c. m. cable for street railway work, which is both weatherproof and lead covered. Another prominent feature is the Chicago rail bond which has been adopted by many leading railroads, and also a handsome assortment of lamp cord, office, annunciator, and magnet wires.

This interesting exhibit is in charge of Messrs. C. W. Bassett, H. C. Willis, and D. P. Fitzgerald, Jr.

THE ALBANY LUBRICATING COMPOUND AND CUP CO. displays a full line of their well-known Albany grease goods. They also show a new spindle grease cup to be used with their grease.

THE NEW YORK INSULATED WIRE CO. made no exhibit, but received their friends at the Murray Hill Hotel in two rooms secured specially for the occasion, whence none retired unsatisfied.

THE EXHIBIT of the Payne Engine Co. shows one of their 50 horse-power, 10-inch x 10-inch engines, running a 25 kilowatt Card dynamo. The engine has a new type of governor and oiler. The unit runs practically without noise or vibration.

THE ONLY EXHIBIT of its kind is made by Mr. W. Goldstein. It consists of different samples of scale taken from boilers with the use of his scale removing compound. Mr. Goldstein himself shows how valuable an article he handles.

THE EXHIBIT of the Green Fuel Ecoomizer Co. shows an outline of the goods manufactured by the company. It consists of different parts of their economizer and complete drawings of installations made by them. Mr. W. Downs, M. E., is in charge.

THE ADAMS BAGNALL ELECTRIC CO. have succeeded admirably in showing what they can do in the way of making arc lamps. Their exhibit, though small, is very complete, showing all styles of lamps manufactured by them. Mr. A. D. Dorman has entire charge of the exhibit.

BURHORN & GRANGER, agents for the Woodbury engine, exhibited a 9 x 12 Woodbury engine, direct connected to a 25 kilowatt Fort Wayne generator. The novel feature of the engine is the Shepheard governor, which regulates within one-half of 1 per cent. Mr. Burhorn is in charge of the exhibit.

DIXON CRUCIBLE CO. succeed very well in showing what an important part their goods play in the electrical field. Their exhibit consists of graphite boxes for baking electric light carbons and filaments, graphite wedges for winding filaments, etc. Besides this, there is a full line of graphite resistance rods, and lubricating compound.

THE WATERTOWN ENGINE here in operation is a 60 horse-power, 10 x 12 engine direct connected to a 30 kilowatt Eddy dynamo. A striking feature of this exhibit is the fact that the engine and dynamo are not bolted to the foundation, and yet are practically free from any vibration. The engine has a patented governor guard, which attracts considerable interest.

L. KATZENSTEIN & CO. show their metallic piston rod packing. As an example they exhibit a duplicate packing that was used on the high pressure rod of the steamer Priscilla, running at 160 pounds pressure on a 9⅝-inch rod; also a ship joint packing used on the gunboats of the United States Navy. This packing is a flexible hollow brass tube, and suitable for all pressures. Mr. F. T. Halt is in charge.

THE ASHTON VALVE CO. display quite a variety of valves and gauges, including safety valves, steam gauges, clocks, engine register, water relief valves, hydraulic valves, locomotive valves, locomotive muffler valves, etc. In the same booth with the Ashton Valve Co., the Mason Regulator Co. have an exhibit of their reducing valves, regulator pumps, etc. Both exhibits are under the charge of Mr. T. D. Oaks.

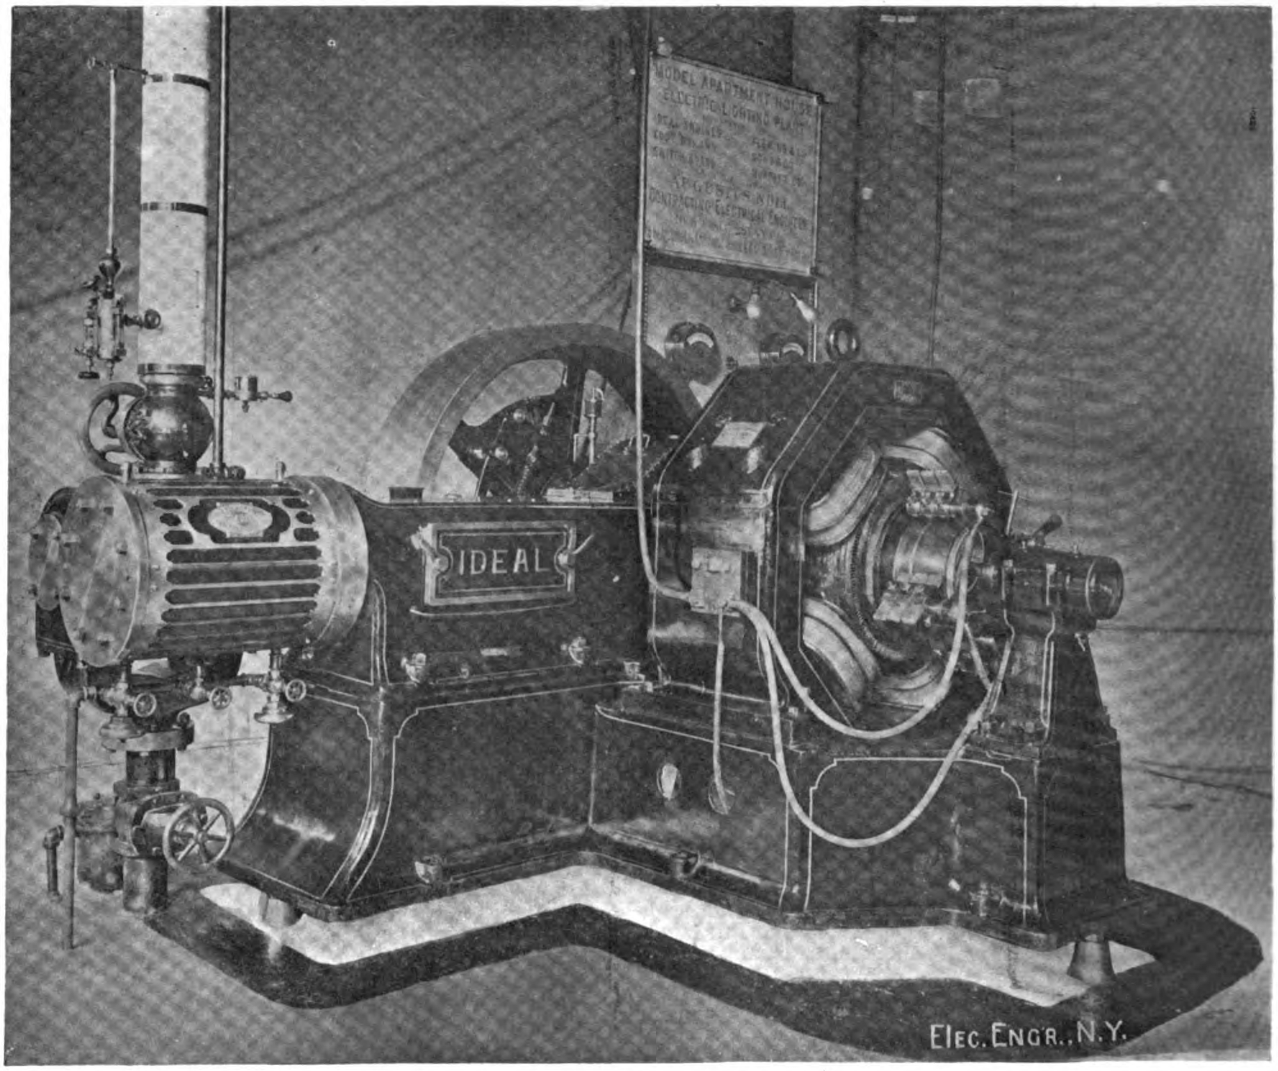
SCHULTZ BELTING CO.—A fine exhibit is made by Mr. A. B. Laurence, of the Schultz Belting Co. It consists of belts of all varieties, including flat sable rawhide, flat sable rawhide grooved, flat sable line or woven belts. There is also shown the Schultz patented pulley cover and rawhide rope, and rolls of 72-inch, 24-inch and 16-inch belts. These belts are the only ones used in the exposition generating plant. A feature of the exhibit is a model of the company's trade mark—a belt between the earth and moon makes the latter spin like a top. Mr. A. C. Laurence did all the electrical work on the model. Mr. A. B. Laurence designed it. The exhibit was in charge of Mr. A. B. Laurence.

THE EDDY DYNAMO AND HARRISBURG "IDEAL" ENGINE EXHIBIT.

If a vote were to be taken among the visitors to the Electrical Exposition as to the finest direct-connected unit in the generating plant, there is little doubt that the Eddy dynamo and Harrisburg "Ideal" engine unit would carry the day, if one may judge by the comments one hears.

This generator was the first to go into operation at the exposition, and from the very start has been called upon to carry continuously an overload varying all the way from 10 to 40 per cent., which it has done without a murmur, so to speak. This would speak well for the combination in any event, but when to this is added the fact that the unit rests on but three steel points without foundation bolts or fastening to the foundation whatever, the fact accomplished will be better appreciated. As our engraving shows, the unit is supported on three points, one placed under the cylinder end of the engine, one under the crank end, and one under the dynamo. These steel points raise the whole about four inches above the floor level, and incandescent lamps placed within the base frame illuminate the floor space occupied by the engine and serve to convince the skeptical that there is daylight between the engine and the foundation.

The combination is of 50 kilowatts capacity, and runs at 280 revolutions per minute. It shows to what a fine point high-speed machinery has been brought in the matter of quiet running and freedom from vibration, and demonstrates that it is possible to have an electric plant in full operation in a room where ordinary conversation is going on without disturbing the conversers in any way, and that the old roar of a central station will soon be a thing of the past. The exhibitors of this combination, Messrs. Coho & Co. and Messrs. Fleming & Co., of No. 203 Broadway, New York, ask us to say that they will be glad to show interested parties a number of modern apartment and office building plants in operation at any time.



THE EDDY DYNAMO AND HARRISBURG "IDEAL" ENGINE UNIT ON STILTS, AT THE ELECTRICAL EXPOSITION.

THE GENERAL ELECTRIC CO.—The space occupied by the company is at the base of the south wall of the main hall. It is inclosed by a pillared cornice studded on the outside with a line of special 6 c. p. miniature yellow lamps broken at the top of each pillar, and on the inside with 240 volt, 16 c. p. frosted lamps. Above the space against the wall is a large monogram, with the initials of the company set in different colored miniature lamps.

The right of the space is occupied by a stand supporting a number of swivelled frames containing photographs of some of the important work done by the General Electric Company, such as the 96-ton Baltimore and Ohio electric locomotive, the great Portland and Sacramento power transmissions, and other installations of similar magnitude. To the left of the space stands an ornamental iron standard carrying arc lamps of the constant potential, long-burning, direct and alternating incandescent and power circuit types. On the tables are a number of samples of the new line of measuring instruments for alternating circuits, some of the new alternating current fan motors, and two samples of the new type H transformers. The space is inclosed with a unique railing formed of railway feeder cable supported by insulated suspension and turnbuckles.

The Miniature Lamp Department has an exhibit of its own placed in a small room to the left of the main space. The principal feature of this is a display board, on which is mounted a sample of every kind of incandescent lamp, outside the miniature category, manufactured by the company. On a stand in the center of the room are two boards, one

carrying a variety of samples of candelabra, miniature and decorative lamps, and other samples of battery lamps. In this case, the smallest incandescent lamp manufactured is shown—about the size of a small pea.

Several of the ornamental illuminated designs gotten up by this department are used to embellish the room. Attached to the ceiling is a beautiful sun; the wall is adorned with a four leaved clover and horseshoe, and a patriotic device with the eagle surmounts the U. S. shield, on which the colors are shown in small lamps. The two other designs are entitled "Mischief Brewing," and "Homeward Bound." The first represents a little witch bending over a seething pot beneath which glistens a red fire, while fays and sprites appear and disappear and a grewsome green-eyed cat glowers from beneath the witch's pointed hat. 'Homeward Bound" is a full-rigged shop tossing and pitching on her way through the moonlit waters, her port and starboard light showing as she appears sailing toward the spectator.

The company was represented by Messrs. S. D. Greene, J. R. Lovejoy, W. L. R. Emmet, J. Kirkland, H. C. Wirt, W. Fenton and J. M. Andrews, of the Schenectady office; Messrs. Charles T. Hughes, T. Beran, C. Gundaker, C. G. Davenport, George De B. Greene and others, from the New York office; Messrs. C. B. Davis, F. M. Kimball, Haley, Ives and Bush, of the Boston office; H. J. Buddy, of the Philadelphia office; W. F. Hays, of the Cincinnati office; A. E. Giles, of the Atlanta office, and Messrs. A. D. Page, M. K. Eyre and McAllister, of the lamp works, at Harrison, N. J.

PERSONAL.

ARCHIBALD J. MARTIN.

WE give herewith the portrait of Mr. A. J. Martin, the electrical engineer of the exposition now being given under the auspices of the National Electric Light Association. He first entered the electrical field in 1880 with the old concern of Arnoux & Hochhausen, merged later into the present well-known Excelsior Company. In 1884 he resigned to accept a position with the Thomson-Houston Electric Company, in connection with the work of installing stations and operating them. This work he continued down to 1890. Among the large plants thus put in by Mr. Martin was one, on the Thomson-Houston system, for the West End Electric Company, of Philadelphia, costing over $400,000, and another for the Germantown Electric Company, of Philadelphia, costing over $200,000.

A. J. MARTIN.

During the past three years Mr. Martin has been connected with Mr. John A. Seely as superintendent of construction. The Fourth Street Railway Company's station of St. Louis is one of the latest plants installed under Mr. Martin's supervision. Those who have come in contact with him in the exposition work have found him alert, energetic, courteous and full of executive ability. The work of getting the power plant and wiring of such a remarkably large expositon in shape within practically a week has been literally gigantic, but it has been carried out with great credit by the subject of this sketch.

MR. LUTHER STIERINGER.

While studiously avoiding any official capacity, Mr. Luther Stieringer has placed his eminent expert and executive ability at the disposal of the exposition management, and the good results are visible in every department. Few men have had so much experience in expositions or can tell better what effect will be secured if certain things are done; and where an exposition looms up so suddenly with unexpected importance and magnitude right guidance is at once rare and invaluable. Mr. Stieringer has again earned the hearty thanks of the profession. To specify but one feature, his artistic setting of the Röntgen ray and Edison fluoroscope exhibit must be regarded as one of the most skillful and artistic arrangements of the kind ever attempted. A delicate scientific experiment is shown to thousands under the best conditions, with every accessory helping to secure the desired result.

FREDERIC NICHOLLS.

THE new president of the National Electric Light Association is one of the most representative men to have reached that place of honor and distinction. Of good English birth and German education, he has been a great many years in Canada; while his business relations with the United States have always been intimate, and his friends in this country are innumerable. Mr. Nicholls has long been an active and loyal member of the Association, and was early picked out as an officer for the body. He is not only deeply interested in the success of local plants, in which he has placed large sums of money, but as an electrical manufacturer turning out perhaps the largest variety of electrical apparatus made by any single concern under the British flag, he is able to look calmly and fairly at the commercial questions of the industry, from the standpoint of the seller and the buyer alike. His judgment is sound and shrewd, and he can take long views as well as swift actions.

FREDERIC NICHOLLS, PRESIDENT, N. E. L. A.

As the vice-president and general manager of the Canadian General Electric Company, Mr. Nicholls is held in high esteem in manufacturing circles in Canada, where he is also distinguished as being with tongue and pen a foremost advocate of a protective system for the Dominion. He is also director in the Toronto Electric Light Company; president of the Brantford Street Railway Company; vice-president of the Peterboro Street Railway Company; secretary of the London Electric Light Company; and director in the Toronto and Scarboro Railway Company. A number of other enterprises all looking to the development of Canada engage his thought, and no man is more anxious for her growth and prosperity in friendly touch with America while without loss of affection for the mother country. In Toronto where the Canadian General Electric Company has its official headquarters, Mr. Nicholls is to be found handsomely installed in a fine big building where the product of the big Peterboro factory is marketed.

PROF. ELIHU THOMSON.

The whole electrical community will be distressed to learn that Prof. Elihu Thomson while riding a bicycle tandem last week had the misfortune to encounter a boulder and break an ankle bone. His presence at the convention and exposition had been confidently looked for, and it is widely hoped that he may be able to get about in time to attend and give a few demonstrations with his own apparatus. It is a curious coincidence that the same week Mr. Edison trod on a buckle and wounded his foot quite severely, but not so as to prevent his walking.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

WESTERN TELEPHONE CONSTRUCTION CO.'S PROGRESSIVE WORK.

We have the subjoined item of news from the Western Telephone Construction Company of Chicago:

"The Western Telephone Construction Company during the past week closed the largest single contract for a telephone exchange equipment ever made, either by an independent manufacturer or by the Bell Company. The contract covers nearly seven thousand telephones and switchboard equipment to match. This equipment is for a large American city, the location being still kept secret. It is asserted that this system will demonstrate a central office system as much superior to the Bell 'Express' system as the latter is to the old Gilliland. It is confidently expected that the new Keelyn system for large exchanges (which has quietly been perfected, awaiting the development of large exchanges) will prove a genuine surprise to the telephone people both in and outside the Bell Company. Competent telephone engineers, who have seen the first installment of these switchboards and witnessed their operation, have been astonished at the simplicity of operation and uniqueness of design for rapid manipulation. Mr. Keelyn's design is a radical departure from multiple drop systems, which, he holds, should have been displaced by better methods long since. Mr. Keelyn has provided a districting system purely original with him, and covered by patents, which admits of extending the system from one thousand to ten thousand, without any radical changes in the switchboards proper. He claims that this is the only method yet devised which will admit of large extensions without change of switchboard, except by the slower type or old transfer-jack systems which he also holds will necessarily have to give way to something capable of rapid and good service. The transfer system requires an extra board for every two boards used in a system of one thousand to twelve hundred, and then, although using a large number of operators, is too slow and troublesome for even fair service. The new Keelyn multiple system only requires the number of drops and jacks to correspond with the number of subscribers' lines.

MICA INSULATOR CO.

The Mica Insulator Company, manufacturers of the well-known insulation "Micanite," whose factories are at Schenectady, New York and London, announce to the trade that they have opened a branch house at 153 Lake street, Chicago, where they will carry a full line of "Micanite" plates, commutator rings and segments and slot insulations for all the standard railway motors and power generators, "Micanite" and empire cloth and paper. The company's goods were formerly sold in Chicago through W. H. Sills & Co., as sales agents. The business will be under the management of Mr. Chas. E. Coleman, who has been connected with the New York house for several years and is thoroughly familiar with the electrical trade. In the circular announcements that they are sending to the trade, they give the assurance that all business will receive prompt and careful attention. On account of the increased business of the company, they have been compelled to establish this branch house, which move will, no doubt, be highly appreciated by the Western customers on account of the excellent facilities which they will have for receiving "Micanite" promptly. Eugene Munsell & Company have also opened a Chicago branch at the came place, under Mr. Coleman's care.

GRUTTING SPECIALTIES.

The Grutting electric soldering iron and curling iron heaters are rapidly becoming recognized as standard goods. The Electric Appliance Company, of Chicago, as general Western agents are carrying a stock of these goods which are meeting with ready sale.

"SHIP" CARBONS OF THE STANDARD PAINT CO.

Mr. John Jordan, of Schiff, Jordan & Company, of Vienna, is now in New York. The Standard Paint Company are sole agents and importers of the "Ship" carbons manufactured by Schiff, Jordan & Company, and Mr. Jordan is here looking over matters generally, and before returning will visit all the large cities in the United States. The company are now making an active push on carbons with very gratifying results. We quote from a letter just received from one of their best customers: "As far as we can learn all of our customers to whom we have sold the 'Ship' carbons have found them perfectly satisfactory." The Standard Paint Company have just received large consignments of carbons from Vienna and are therefore in a position to fill orders immediately from stock.

ARMORITE INTERIOR CONDUIT.

The Armorite Interior Conduit Company, of 478-480 Fort street, West, Detroit, Mich., have issued a little pamphlet and price list describing their new Armorite system of interior conduits.

The tubes are made any size from 5/8 inch inside diameter to 3 inches, all 10 foot lengths. The tubes are lined with a thoroughly prepared wood, cut in semi-cylindrical sections and forced into the armor, making, when complete, insulation of the highest character.

The Armorite system is claimed to possess many advantages over the present method of installing iron conduit. Ordinary bends up to 1-inch conduit can be made cold on the job by the workmen.

THE HOPE ELECTRIC APPLIANCE CO., of Providence, R. I., report business very good in the specialties which they make, an excellent idea of which may be had from consulting their page advertisement in this week's issue. Mr. Robert A. Fessenden, treasurer of this company, was recently in New York, and favored this office with a call, when he informed us that they were now putting on the market a new knife motor switch in which the make and break is instantaneous, and the movement cannot possibly be centered. The company have recently been reorganized and are now in good shape to fill orders promptly and to manufacture a first-class line of electrical specialties.

THE AKRON SMOKING PIPE CO. have moved their factory to Mogadore from Akron, O., where they have an extensive new plant, and are turning out a vast quantity of porcelain to fill the increased orders, which they have recently received. The company has found considerable demand for their goods in the East as well as West.

H. B. CAMP CO., of Aultman, O., have had very great success with their vitrified clay conduit, which is laid in mortar or cement, making it capable of sustaining great weight in case of being undermined, as it is then one continuous solid cemented mass. The conduit is laid with the patent mandrel system of Mr. Camp. The conduit is extensively used in different parts of the country. The Cataract Construction Company have employed it; the Metropolitan Street Railway Company, Washington, D. C., have used 50,000 feet; Pittsburg, Pa., has 800,000 feet, and in Philadelphia there are 900,000 feet in use.

DORNER & DUTTON MANUFACTURING CO., Cleveland, O., report business good and the outlook for the coming year as bright. They are filling an order for seventeen trucks, D. F. Henry patent, for the Federal Street and Pleasant Valley Railway, of Pittsburg, Pa. They also are building thirty of their 25-A trucks for the Fort Wayne Consolidated road, and have recently shipped five trucks to Bangkok, Siam, where there are already twenty-five in use. This company is just bringing out a novel car heater for electric roads, which is light, compact and economical. The company is also the agent of the Compo Brake Shoe for the Central, Western and Southern States.

ON WEDNESDAY, MAY 20, at 12 o'clock, at the Real Estate Salesroom, No. 111 Broadway, New York, exclusive selling right under Letters Patent No. 457,842, covering the swinging ball lightning arrester, also Letters Patent No. 284,460, relating to cloth steepers for copying presses, will be sold at public aution.

MR. FRED M. LOCKE, of Victor, N. Y., has had some very flattering testimonial letters from electric light men and others concerning his specialties. His insulator pin is guaranteed against breakage, and his porcelain insulators will carry any amount of current safely. He is paying particular attention to the overhead construction of lines for all classes of electrical work.

THE MECHANICAL AND ELECTRICAL MANUFACTURING CO., of Brooklyn, begins business with a capital stock of $50,000. Among those interested are E. Denning, W. E. Dillman, C. Olsen, and W. G. Lord, of Brooklyn, and Ely Pullen, of Jersey City.

THE NON-POLARIZING DRY BATTERY CO. has been formed in this city by J. C. Kaempter, J. Liebes, and A. Liebes, with a capital stock of $100,000.

THE BERLIN IRON BRIDGE COMPANY have issued a neat and pretty calendar for 1896, giving pictures in color of their work in bridges, roofs, power houses, etc.

Department News Items will be found in advertising pages.

POWER TRANSMISSION.

LONG DISTANCE POWER TRANSMISSION AT LOWELL, MICH.

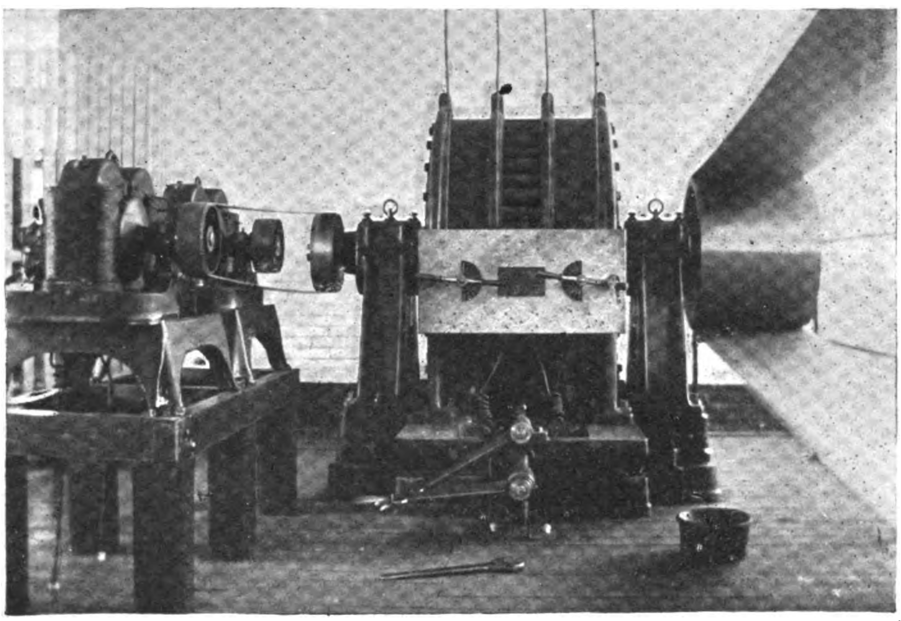
BY J. B. W.

ONE of the most typical and the longest electric transmission plants east of the Mississippi River has recently been installed at Lowell, Mich., by the Lowell Water and Light Company. The power house is situated about one mile east of the town upon the Flat River, a tributary of the Grand. On the east side of the river is a large waste weir, which is used in time of high water. The power house, a substantial brick building, is located upon the west bank.

In the basement of the building are three vertical turbines of 100 horse-power capacity each, two of them being Leffel, and one a new American special. These wheels furnish power for driving one 200 kilowatt "S. K. C." alternating current generator. The pumping machinery which supplies water for the village of Lowell is also located here. The wheels are so arranged that any one may be connected or disconnected to the machine line shaft by means of clutches, thus making it possible to throw any wheel in or out without shutting down the plant. The generator is belted to this line shaft and supplies current at 1,000 volts. The town of Lowell is supplied at this voltage. Step-up transformers raise the current from 1,000 to 10,000 volts, and at this high potential supply the transmission line upon which it is carried to Grand Rapids, eighteen miles away; there it is reduced by means of step-down transformers to 2,000 volts and distributed for light and power indiscriminately. Eight thousand alternations are used in this work, and the motors of the "S. K. C." type with condensers are used exclusively for power.

The marble switchboard in the Lowell station is perfect in its adaptation and equipped with the best apparatus obtainable for high voltage work. Two double-pole switches and two "S. K. C." circuit breakers control the Grand Rapids line, while the Lowell circuit is similarly controlled. The generator is furnished with regulator heads by which the voltage of either phase may be raised or lowered independently of the other, thus making it possible to throw the load of the Lowell circuit upon either phase, and yet maintain a perfect balance of voltage at Grand Rapids, over eighteen miles away.

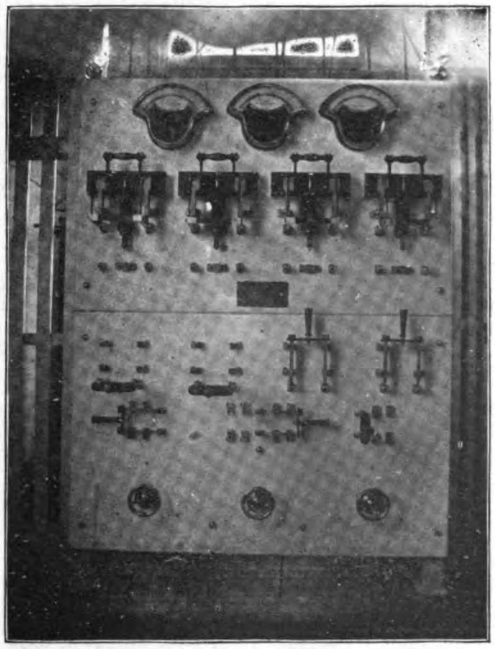
THE DAM AT LOWELL, MICH.



S. K. C. GENERATOR AND EXCITER.

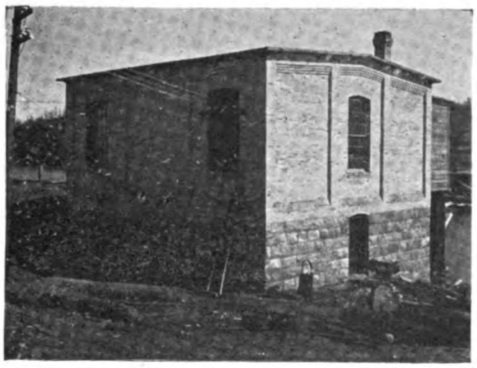
The pole line is of the most modern construction, and very substantial, consisting of 30-foot poles, with not less than six-inch tops, set 100 feet apart. The four No. 6 wires are carried upon two cross-arms, and are so arranged as to make a square having 18 inch sides, the diagonal wires of which form the circuits for each phase of the generator. They are sup-

ported upon the Locke triple petticoat porcelain insulators, which give very perfect insulation, the leakage being extremely



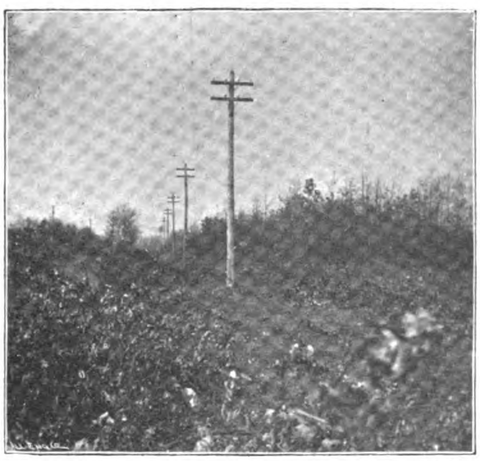
THE SWITCHBOARD AT LOWELL.

small, even with a pressure of 12,000 volts upon the lines. The circuits are protected from lightning discharges by string-



POWER HOUSE AT LOWELL, MICH.

ing a barbed-iron wire over the tops of the poles, which wire is grounded at every other pole. For indicating grounds upon the high voltage lines static ground detectors are used.



THE TRANSMISSION LINE.

The Stanley Electric Manufacturing Company, and the Lowell Water and Light Company, have in this installation practically demonstrated that power can be carried long distances at high voltages through a thickly settled region and distributed for an indiscrimate use of arc, incandescent lights and power with perfect success, and that by using these high voltages the losses in the lines can within a commercial basis be reduced to less than the average losses in the distributing circuit of low tension direct current central stations in large cities.

The officers of the company are O. C. McDonald, president; Charles A. Church, secretary and treasurer; L. W. Kutsch, superintendent. The pole line was constructed under the supervision of Mr. M. M. Wood, of Chicago, and the installation of the electrical equipment was made by W. B. Jackson, one of the engineers of the Stanley Electric Manufacturing Company.

ELECTRIC LIGHTING.

SOME ACCOUNT OF THE EVOLUTION OF THE INDUCTOR ALTERNATOR.[1]

BY JOHN F. KELLY.

In beginning this brief sketch of the evolution of the inductor alternator,[2] I wish to define my conception of the type, and I have found it necessary to include some machines not usually regarded as inductors. An inductor alternator, as I understand it, is one in which the electromotive force in the induced coil is the result, not of changes in the space relations between such coil and the flux-producing agency, but of changes in the flux through said coil, brought about by the motion of iron pieces serving as magnetic conductors. When the flux is due to an exciting coil, the foregoing definition requires constancy of the space relations between the exciting and the induced coils, and in general this constancy of relationship is mechanically expressed by the entire immobility of both coils. It is, however, possible that the inducing coil should turn on its

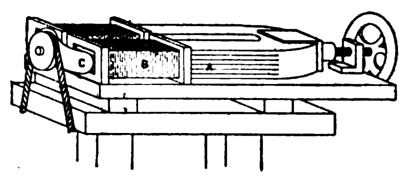


FIG. 1.—KNIGHT, 1854.—A, INDUCING MAGNETS; B, INDUCED COILS; C, ROTATING KEEPER.

axis without in any way altering its relationship to the induced, and in some cases this is the construction adopted.

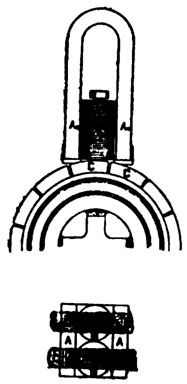
As a means of producing electric energy on a large scale, the inductor alternator is the latest claimant for public favor, and yet it is far from being a newcomer. Its advantages have been apparent from the earliest days of the art, and a long series of distinguished inventors have worked at its development. Although until about eight years ago it was an extremely inefficient generator, its extreme simplicity secured it an introduction when not much power was required. Indeed, if we bear in mind that the Bell telephone considered as a translating device, is an inductor alternator, we shall have to regard the inductor as the most widely used type of alternator. Our concern here, however, is only with machines useful in

[1] Read before the N. E. L. A., New York, May 5, 6 and 7, 1896.

[2] The almost exclusive reference to English inventors in this paper is not due to underrating the efforts of others, but solely to lack of space and time. It would have been impossible to give adequate recognition to all, and it happened to be more convenient for me to trace the development along English lines until the last stage than along any other. I have no doubt that a parallel history might be written for any of the important cultured lands. At the present time the art of inductor building is more highly developed in the United States and on the European Continent then in England. Indeed a mere mention of the name of the engineers on the Continent, engaged in the development of inductor machines—Rühlmann, Dobrowolsky, Arnold, Kolben, Brown and Thury—is sufficient evidence that their work must be of importance.

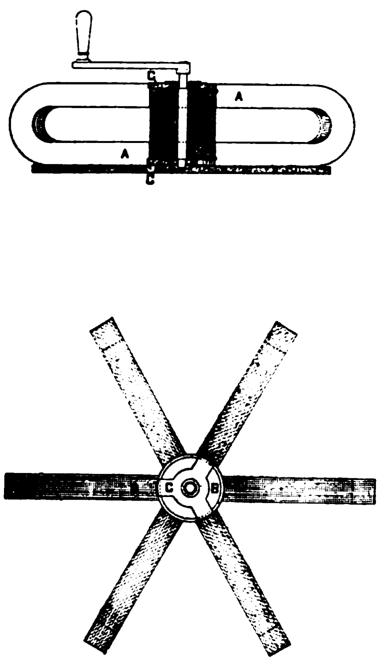
large sizes, and any others are of interest only as foreshadowings.

I shall first call your attention to Knight's machine, shown in Fig. 1. This machine was patented in 1854 in England. Its defects are obvious, but it should not be overlooked that it is



FIGS. 2 AND 2A.—HENLEY, 1856.—A A, INDUCING MAGNET; B B, INDUCED COILS; C C, KEEPERS.

not worse than its rivals of other types, and, indeed, no worse than most of the modern magnetos for signaling purposes, while it is unquestionably of a more robust construction. Henley's machine, Figs. 2 and 2a, consists of an inducing magnet with an electro-magnet set between its poles and in a plane at right angles to them. A double series of rotating keepers connects first one pole of the electro-magnet to the north pole of the inducing magnet, and the other to the south pole, and then reverses these connections, thus giving use to an alternating flux through the electro-magnet. Figs. 3 and 4 show an interesting design of Wheatstone's. There is but a single induced coil, within which moves an iron cylinder provided at each end with radial polar extensions. This single coil form has been



FIGS. 3 AND 4.—WHEATSTONE, 1858.—A A, INDUCING MAGNETS; B, INDUCED COIL; C C, KEEPERS.

taken up again by recent inventors, but has not yet come into use. Like Knight's machine, this of Wheatstone's suffers from the great variation in the magnetic flux in the inducing magnets. Wheatstone says that the inducing magnets in this machine may be electro-magnets. Fig. 5 shows another design of Wheatstone's, which shows considerable improvement over the other. The variations of magnetic flux are here confined to those portions of the magnetic circuit in which it is necessary they should occur. The flux as a whole is steady, and the machine operates by its varying distribution, the keeper now directing the flux through one pair of induced coils, now through the other. Wheatstone does not appear to have had this reason in mind in duplicating the induced pair of coils. His object appears to have been to secure a smoother electro-

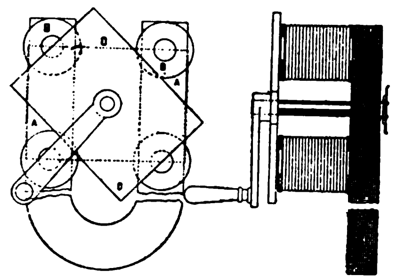


FIG. 5.—WHEATSTONE, 1858.—A A, INDUCING MAGNET; B B, INDUCED COILS; C C, KEEPERS.

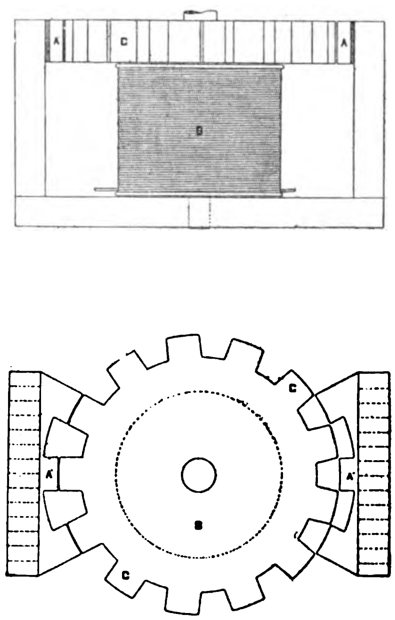
motive force curve. This machine was introduced into telegraphy, and I am assured by Mr. Stephen D. Field that it gave first-class service. The Lippens machine, shown in Fig. 6, is

FIG. 6.—LIPPENS.—A A, INDUCING MAGNETS; B B, INDUCED COILS; C C, KEEPERS.

so like Wheatstone's first design that it needs no description. A machine designed by S. M. Martin and S. A. Varley is shown in Figs. 7 and 8. It consists of two inducing magnets, with an induced magnet between them, connected to the soft iron yoke.

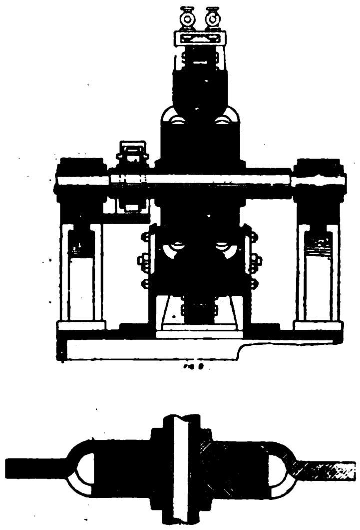


FIGS. 7 AND 8.—S. M. MART N, S. A. VARLEY, 1868.—A A', INDUCTOR POLES; B B, INDUCED COIL; C C, KEEPERS.

A revolving, toothed iron disc alternately closes the magnetic circuits of the two inducing magnets through the induced magnet. This machine may be considered to be Henley's, with one

limb of the electro-magnet suppressed, and only one limb of the inducing magnet in action at a time.

The machine described by Holmes, Figs. 9, 10 and 11, in his English patent of 1868, is worthy of considerable attention. In some respects it may be considered as an inversion of Wheatstone's first design. A single exciting coil gives rise to a number of poles, while the induced electro-magnets are separate and distinct. An interesting feature is that the cores of the induced magnets are slotted to prevent Foucault currents. The exciting coil feature has been adopted in all modren inductors with which I am acquainted, save one, and the sub-division of the iron in armatures to prevent Foucault currents has become a matter of course. Yet, in respect to the steadiness of the flux, this machine is distinctly retrogressive and decidedly inferior to Wheatstone's second design. Holmes intended the machine for electric lighting, but I am not aware of its ever having come into practical use.



FIGS. 9 AND 10.—HOLMES, 1868.—A′ A, INDUCTOR POLES; A A, EXCITING COILS; B B, INDUCED COILS; C C, KEEPERS.

Gramme's invention came near putting an end to work on inductors, as, indeed, to work on alternators of any kind. Yet, in the time intervening between the introduction of the Gramme machine and the resurgescence of the alternator, provoked by the introduction of the modern transformer, C. F. Varley[1] designed an inductor, Figs. 12 and 13, which deserves mention for its novelty. The induced coils are subject to the influence of two inducing magnets which tend to develop opposite fluxes through them. These magnets are alternately short-circuited by the keepers, and, in consequence, the flux through the induced coils is alternated by arranging the keepers so that they begin to short-circuit one inducing magnet before entirely open-circuiting the other; the flux in the inducing magnets is kept more or less constant. In this same year, Paul Jablochkoff took out an English patent for an inductor alternator. It is of the single induced-coil type; but were it not for the inventor's great fame, considering the date, it would not be worth attention.

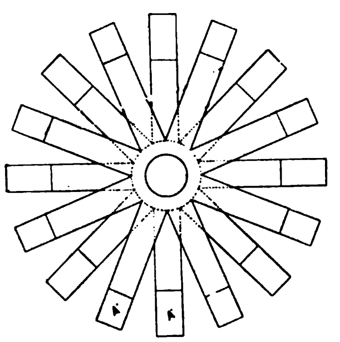


FIG. 11.—HOLMES, 1868.—A A, INDUCTOR POLES.

Even the best of these early inductors must have had vast iron losses. In most cases there was no thought of preventing them, and, when preventive measures were adopted, they were entirely inadequate. The mass of iron subject to magnetic change was always, relatively to the size of the machine, enormous, thus necessarily increasing the hysteresis loss; while no sufficient provision appears to have been made for the prevention of Foucault currents. The machine of Klimenko, exhibited at Vienna, which required more power to drive it when running light than when loaded, was not, I think, exceptional.

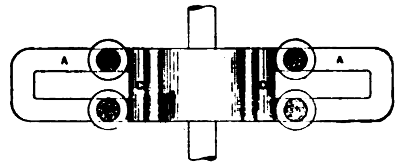

FIG. 12.—C. F. VARLEY, 1877.—A A, INDUCING MAGNETS; B B, INDUCED COILS; C C, KEEPERS.

In 1887, Mordey cut the Gordian knot by entirely suppressing the iron in the induced portion of the machine. The highly and deservedly successful machine that bears his name is shown in Figs. 15 and 16.

There is a central core surrounded by the exciting coil, A. From each end of this core projects a set of radial polar arms, which are recurved so as almost to meet one another. In the space left free are mounted the thin induced coils, BB, in a circle. The induced coils are wound in the plane of this circle, and are in number twice the polar faces on one side. The induced coils are fixed and the inducing magnet revolves. The exciting coil turns with the core, but this is electrically immaterial, and the results would be the same were it at rest. Obviously, the total reluctance of the magnetic circuit is the same, no matter what the position of the inductor. Change of flux in the iron is due only to armature reaction, and it gives rise to iron losses only because of its space variations. With a low armature reaction, such losses will be extremely small.

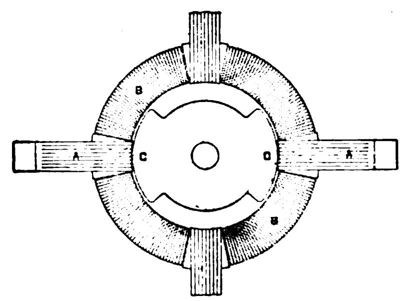

FIG. 13.—C. F. VARLEY, 1877.—A A, INDUCING MAGNETS; B B, INDUCED COILS; C C, KEEPERS.

Mordey's success, instead of putting an end to attempts to build inductors with iron in the induced portions, gave rise to a new series of efforts. Indeed, Mordey himself was foremost. His English patent of 1887, relating to the coreless armature machine, also described a machine with cores, and in subsequent patents he describes the machines shown in Figs. 17, 18, 19 and 20.

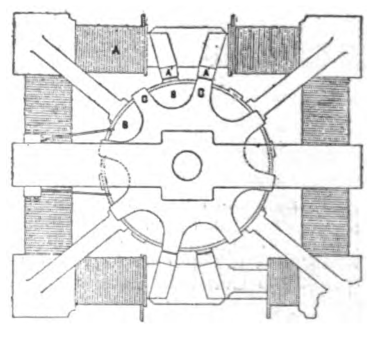

FIG. 14.—P. JABLOCHKOFF, 1877.—A A′, INDUCTOR POLES; A, EXCITING COILS; B B, INDUCED COILS; C C, KEEPERS.

[1]The figures of C. F. Varley's machine were made entirely from description. They may be quite different from those in his patent.

These machines have not come into use, and, presumably, they are not as satisfactory as the coreless machine. Yet they show a marked advance when compared with the older machines. The use of the short-circuiting pieces, C′, as well as the bridges, C, tends to make the flux constant in amount and to restrict the magnetic changes to the induced portions of the

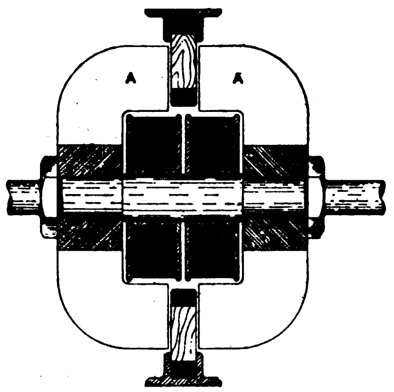

FIG. 15.—MORDEY, 1877.—A A, EXCITING COILS; A′ A′, INDUCTOR POLES; B B, INDUCED COILS.

machine. The iron subject to magnetic change is also properly laminated to prevent Foucault currents. The most obvious fault in the designs is that the mass of iron in the induced portions is large, and that all of it is subject to hysteresis loss.

In passing, it may be worth while to note one peculiarity of single induced coil machines like the earlier of the Mordey

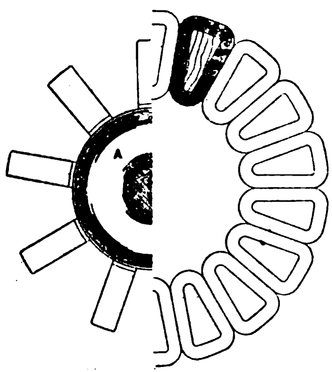

FIG. 16.—MORDEY, 1887.—A, EXCITING COILS; B, INDUCED COILS.

designs. With any given frequency, the output is independent of the speed; or, in other words, the only limit to reduction of speed is the possibility of further sub-dividing the poles. For, with the number of poles increased N times, the total change of flux takes place with 1/Nth the angular motion. This remarkable property may some day bring about the introduction of

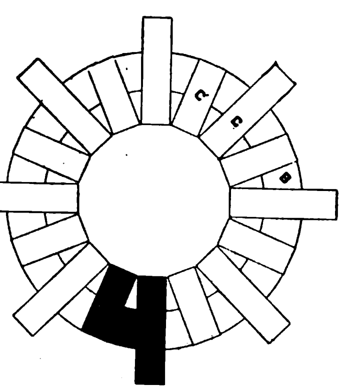

FIG. 17.—MORDEY, 1888.—B, INDUCED COIL; C C, KEEPERS.

machines of this class for direct connection to very slow-speed engines.

The Kingdon machine, Fig. 21, is a modernized Henley machine. The exciting and induced coils are wound on the alternate polar projections, and the magnetic connections between the inducing and induced cores are alternately reversed by the rotating keepers, C. The whole of the iron in the machine appears to be subject to hysteresis loss. Foucault currents are checked in the usual manner by lamination. In this machine, if the induced coils are so wound that they may be worked in parallel, it is possible to reduce the iron losses in proportion to the load by cutting out both inducing and induced coils in the same degree. I hardly think that this advantage is sufficient to countervail, having the hysteresis loss too high to begin with. A few of these machines were put into practical use, but I think not many.

The machine designed by Rankin Kennedy in 1890 is a twinned form of the Mordey, shown in Figs. 17 and 18, with the short-circuiting pieces, C′, left out. This necessitates the

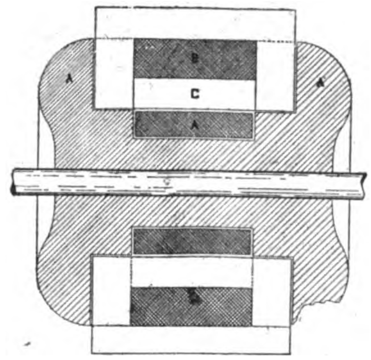

FIG. 18.—MORDEY, 1888.—A A, INDUCTOR POLES; A, EXCITING COIL; B, INDUCED COIL; C, KEEPER.

lamination of the whole of the iron, and subjects it all to hysteresis loss. The twins are so arranged that the induced electromotive forces in the inducing coils are in opposition, so as to prevent the development of alternating currents in the inducing circuit. The machine has not, I think, been practically introduced, and in my judgment it is less fitted for use than its prototype.

The modern machines thus far described lend themselves badly to polyphase working. This is true even of the standard Mordey, while as to the others, adaptation to polyphase means practically duplication or triplication of the whole machine. As polyphase machines, they are merely mechanical combinations of single-phase machines. A machine adapted directly to polyphase working, on the other hand, regulates more closely and is more efficient as a polyphase than as a single-phase machine. The machines that follow are all suitable for polyphase.

The first of them, Figs. 22 and 23, is due to one of the masters of our profession in this country, and would even on this account alone be worthy of attention. But mechanically, in the robustness and simplicity of design, it seems well in advance of its predecessors. The induced coils are well secured and out

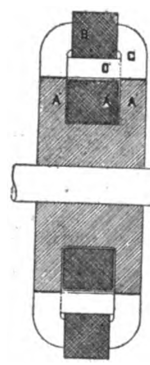

FIG. 19.—MORDEY, 1889.—A, EXCITING COILS; A A′, INDUCTOR POLES; B, INDUCED COILS; C C, KEEPERS.

of harm's way, and the only moving pieces in the machine are the shaft and the single star-shaped inductor. The adaptation of the machine to single, two or three-phase working is merely a matter of the number and grouping of the induced coils. The duplication of the exciting coil is not, I think, to be considered an improvement. High hopes were entertained of the future of this machine. Of the causes of their frustration it is not for me to speak.

The operation of the Pyke and Harris machine will be clear from the drawings, Figs. 24 and 25. The machine consists of a pot magnet with a central core. At the bottom of the pot

lies the inducing coil, A. The lip of the pot and the core carry inwardly and outwardly projecting laminated polar extensions which support the induced coils, B. Between these polar extensions move the rotary laminated keepers, C. What I have called keepers here, on account of their appearance and size, really correspond to the inductor in the Thomson machine, and in that which follows, for they normally constitute that

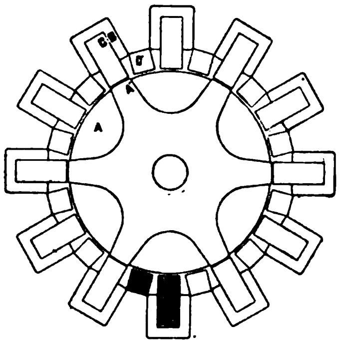

Fig. 20.—Mordey, 1889.—A, Exciting Coil; A', Inductor Pole; B, Induced Coils; C, Keepers; C', Short Circuit Keepers.

portion of the machine in which the flux is most invariable. There is no reason why a machine of this form should not be all right electrically if well designed. Mechanically, however, it seems to sacrifice that very simplicity which makes inductors desirable.

I now come to the machine with which I am best acquainted, and in whose designing I took part. For these reasons I may

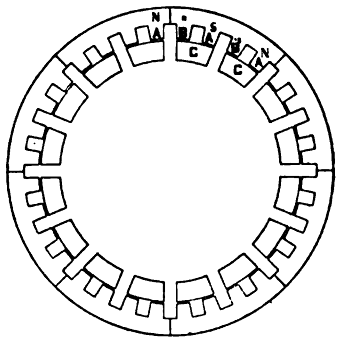

Fig. 21.—Kingdon.—A A, Inductors; B B, Induced Cores; C C, Keepers.

be pardoned for going more into detail in the description, since they enable me to give more information. Coming after that of so many able engineers, it is scarcely to be expected that the work of my colleagues and myself should result in any startling change in form, and, in fact, our improvements are not such as to catch the eye. They, however, have made the inductor alternator with iron-cored armature a success; so

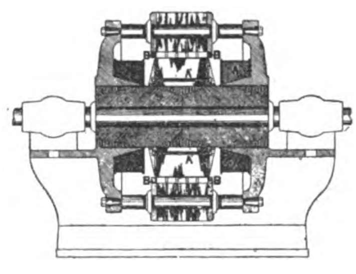

Fig. 22.—Thomson, 1890.—A' A', Inductor Poles; A A, Exciting Coils; B B, Induced Coils.

much so, that I have no hesitation is saying that the inductor is not only the alternator of to-morrow, but that it is the alternator of to-day.

Figs. 26 and 27 show clearly the construction of the machine. The rotary inductor is a cylindrical steel casting with outwardly projecting, laminated pole pieces at either end. The armature consists of two rings connected by wrought-iron tie bars. The induced coils are sunk below the surface in grooves in the armature rings, and the stationary exciting coil lies in the space between the pole-pieces and the armature rings. The machine is very effectively ventilated by means of openings in in the armature rings, and the stationary exciting coil and the spaces between the tie bars. The exciting coil itself is protected from injury by a massive hollow ring of cast copper, inside which it is wound.

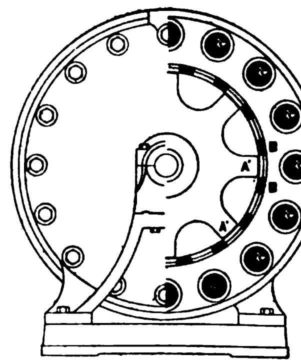

Fig. 23.—Thomson, 1890.—A' A', Inductor Poles; B B, Induced Coils.

I have already called attention to the importance of keeping the flux constant in the inductor, so as to avoid hysteresis and Foucault-current losses therein. The only thing tending to disturb the inductor flux is the varying reluctance caused by change in the relative position of the armature slots and the inductor poles. To keep this at a minimum is the chief reason

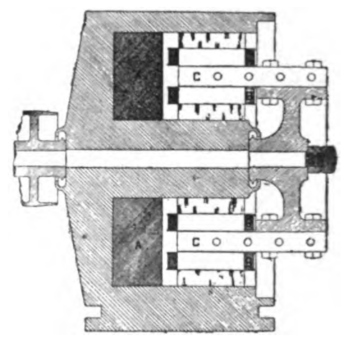

Fig. 24.—Pyke & Harris, 1892.—A A, Exciting Coils; B B, Induced Coils; C C, Keepers.

for preferring a double wreath of induced coils to a single one. Mechanical interruption at both ends is necessary in either case, and it is wise to take advantage of it in distributing the induced coils. With the same amount of wire, the space variation of reluctance is much less when both air-gaps are utilized than when only one is, and, at the same time, the regulation of

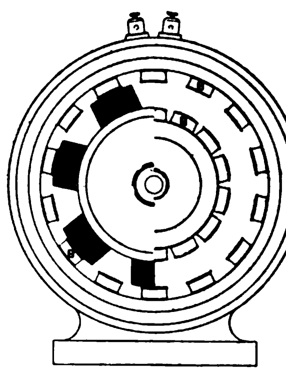

Fig. 25.—Pyke & Harris, 1892.—B B, Induced Coils; C C Keepers.

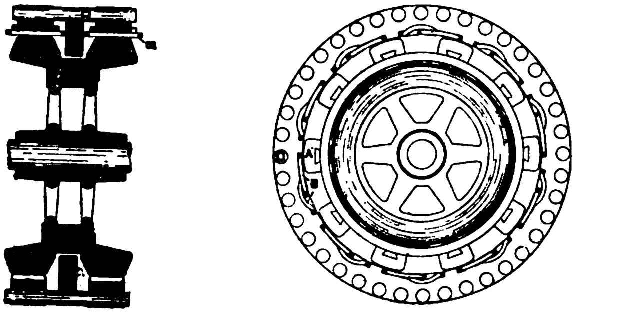
the machine is better. As complete lamination of the body of the inductor is difficult, even a slight change of flux is to be sedulously avoided. Lamination of the pole-pieces is necessary, even with constant flux, as the slots necessarily change its distribution.

But, even with the flux through the inductor constant, the

difficulties are by no means surmounted. A large mass of iron in the armature is a necessity of the construction, and the losses in this way may be such as to make the machines practically inoperative. Only thorough lamination would put an end to the Foucault losses, and thorough lamination is, for structural reasons, out of the question. Another solution is imposed. Now, when the flux is constant in the inductor, it is obvious that in amount it must also be constant in the armature. It but shifts in position without altering in magnitude. But to give rise to the electromotive force in the induced coils, it is unnecessary that the shift should take place throughout



FIGS. 26 AND 27.—"S. K. C.," 1893.—A, INDUCTOR POLES; B, INDUCED COILS; C, KEEPERS.

the mass of the armature. It is necessary only that the shift should take place through the coils; that is, to the depth to which the coils are embedded. The problem is, therefore, to combine a steady flux in the center of the armature with a shifting flux in the armature faces; or, in other words, the distribution of the flux in the middle of the armature must be independent of the points in the faces at which the flux enters. Stated in this way, analogy with the conditions of electrical distribution in parallel is suggested and this points to the solution. Consider for a moment the two laminated rings as electrical mains and the tie bars as translating devices. Then, if the two mains be of low and the translating devices of high resistance, the current through the translating devices will be substantially independent of the points of attachment of the feeders—the analogues of the inductor poles. Similarly, if the reluctance in the direction of the lamination be low in comparison with that in the direction of the tie bars, the magnetic flux in each bar will be constant, no matter what the position of the inductor poles. In this manner, the change of flux is confined to a small portion of the armature iron, which may be thoroughly laminated, and thus Foucault-current losses are suppressed and hysteresis losses reduced to a minimum. It thus becomes possible to use in the armature any quantity and form of iron demanded for structural reasons.

It will be noticed that the inductor poles are curved in a special manner. This is done to make the electromotive force curve as nearly as possible a sine curve. You will remember that some time ago much space was given up in the electrical journals to a controversy as to the best form of electromotive force wave. Nearly every form of wave found some advocate for some purpose, but somehow the sine wave seemed always to be second best. As we are building machines for general service, we are entirely satisfied with that curve which is second best for each special purpose, believing it to be in consequence the best for general distribution work.

The heavy copper bobbin surrounding the exciting coil, besides being a mechanical protection for the coil, is also of use in that it prevents the development of an excessive electromotive force in either exciting or induced coils, if the exciting circuit should be accidentally broken. It resists very powerfully any sudden change of flux.

An important advantage of all stationary induced-coil machines, and, of course, therefore, of inductors, is the possibility of regulating separate circuits or feeders with little or no auxiliary apparatus. Since it is possible to tap the armature coils at any point, any desired electromotive force between zero and the maximum may be obtained for one circuit without altering the excitation, and, consequently, without interfering with the electromotive force of any other circuit. Circuits or feeders having different drops may thus be provided for. Figs. 28 and 29 show two methods of operation. The coils, AA, in the first are the main inducing coils, giving the electromotive force necessary for all circuits or for the mains in a feeder and main system. BB are the auxiliary or regulating coils. The number of the regulating coils in circuit is controlled by the switches, CC. The diagram shows only two circuits; but, of course, any number may be branched on, each with its own regulating switch. This method is the simpler for the operation of only one or two machines. With a larger number of machines I would recommend the method shown in Fig. 29, as it gives simpler switch connections. In this method, the auxiliary induced coils do not act directly upon the circuits, but only through the intermediary of the auto-converters, D. This method of regulation has the advantage over the ordinary "booster" system that the auto-converter, D, for the same regulation needs to be only one-half the size of the corresponding "booster," and it is, besides, more efficient. The adoption of either method secures the same flexibility and ease of control of

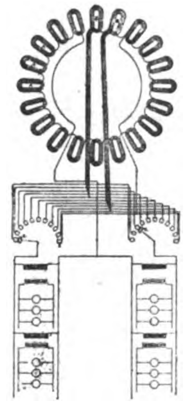


FIG. 28.

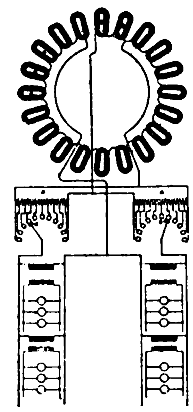

FIG. 29.

the individual circuits as if a separate machine were used to feed each one, while, at the same time, we get the lower first cost and greater economy of operation of large machines.

THE NIAGARA CALCIUM CARBIDE PLANT.

BY ORRIN E. DUNLAP.

THE calcium carbide plant at Niagara Falls is now in operation. This plant is the property of the Acetylene Light, Heat and Power Company, of Philadelphia, and is the first plant of its kind erected in America for commercial purposes. The start was made on April 27. Mr. J. M. Morehead, chief engineer of the Electro-Gas Company, superintended the erection of the plant.

The company claim that they can make carbide for less than $23 per ton of 2,000 pounds, and that this will be improved on. At present a record is made and kept of everything done at the plant, so that in course of time Vice-President Vincent, who is in charge, will have fully accurate data as a basis for computation.

As originally erected the factory was 40 x 90 feet at the foundation. The structure is of brick, the front portion being two stories high. To this building a brick addition 30 x 60 feet has been added to that part which is one story high. Other extensions are in contemplation. The front, or two-story, part of the building is devoted to the crushing and grinding plant, of 50 tons capacity. In the rear of this is the furnace room, containing four furnaces, and adjoining the furnace room on the lower floor is the transformer room. Beyond the furnace room is the storeroom. The laboratory is upstairs; the office on the lower floor. The president of the company, Mr. C. C. Adams, has stated that a continuous furnace is to be added to the plant, the present furnaces not being of that description. This, of course, would be a material factor in lessening the cost of the production of carbide, about which there is so much dispute at present.

The Niagara furnaces shown in the engraving, Fig. 1, each contain a cast iron crucible 3 feet 6 inches long, 2 feet 8 inches deep, and 2 feet 2 inches wide. The electric furnace consists of a horizontal bedplate, or crucible, connected to one

pole of the generator or transformer, and of a vertical carbon pencil connected to the other pole, suspended above the center of the bedplate and capable of moving in a vertical direction.

In starting a furnace in operation the carbon pencil is momentarily placed in contact with the bedplate. The carbon pencil is then raised, imposing an air gap in the circuit. Having established the arc in this manner, the material is fed in towards the crucible, or bedplate, covering the arc and surrounding the pencil to a depth of from two to three feet. The production of carbide begins immediately. The carbide thus

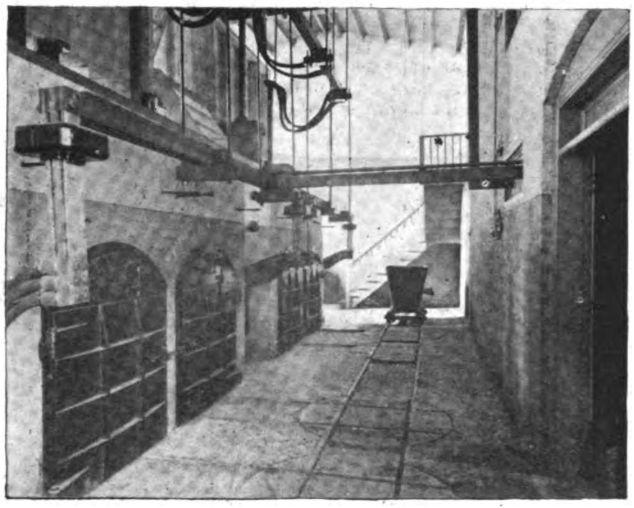

FIG. I.—ELECTRIC FURNACES IN THE CARBIDE PLANT, NIAGARA FALLS.

produced forms under the pencil and tends to close the air gap. As the air gap is shortened the resistance of the furnace is lowered and the load increases, which is shown by the ammeter. The attendant in charge then raises the pencil so as to lengthen the air gap, increasing the resistance and lowering the load to its normal amount. This adjustment is necessary every few minutes. One man can attend four furnaces. In the installation an ammeter showing the flow of current to each furnace is placed in immediate proximity to the carbon-raising device, which controls the carbon for that furnace.

After the process has been going on in this manner for

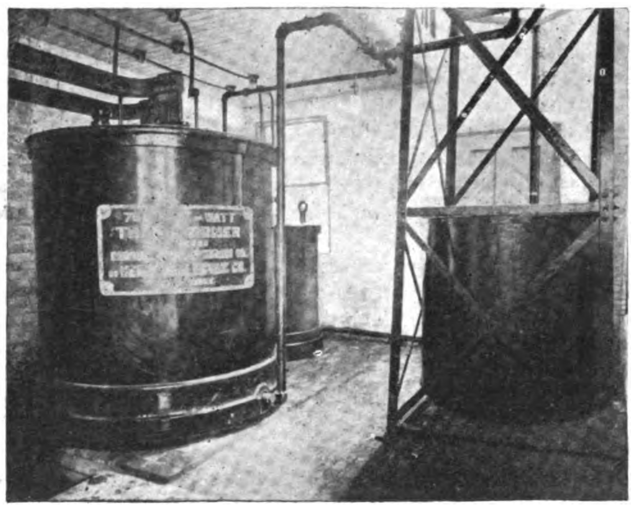

FIG. 2.—750 K. W. TRANSFORMER, CARBIDE PLANT, NIAGARA FALLS.

from one to three hours, a column of carbide from one to four feet in diameter is formed between the bedplate and the bottom of the carbon pencil, the arc being maintained between the top of the column of carbide and the bottom of the pencil. As the carbide formed has a comparatively high electrical resistance, and as this remains in circuit after it is formed, it is economical to stop the process, clear out the crucible and make a new start, after a column of two to six feet—according to the capacity of the furnace—has been produced. The process of drawing a charge consumes from three to five minutes. The carbide is then allowed to cool, after which it is broken up and may be stored for any length of time.

Each of the furnaces at Niagara is designed to consume 500 horse-power. The bedplate in the furnaces at Niagara consists of a cast iron crucible placed on a car, which is run into the furnace on a track under the carbon pencil. A clamping device makes the necessary electrical contact on the side of the crucible. The "pencils" consist of six carbon slabs 46 inches long, 4 inches thick, 8 inches wide, at lower end, and 16 inches wide at the upper. These are clamped in a cast iron holder, which in turn is secured to the end of a copper rod 3½ by 3½ inches. Flexible copper cables are fastened into the upper end of this rod to permit of a vertical movement of about 12 feet. The carbon pencils, the carbon holder, and the rod are all counterpoised to lessen the work and facilitate the raising and lowering of the upper electrode. After the arc is started the mixed material is fed into the crucible by opening the chute and allowing it to drop in from a bin located above the furnaces.

The furnaces at Niagara, for the present, are wired in parallel and two are in operation at the same time. Some dioxide of carbon is produced during the process and this carries out of the furnace, mechanically, a small portion of the lime and coke. To provide a settling chamber in which this can be recovered a flue 12 feet long, with hanging walls and diaphragm, is built back of the furnaces and along the floor to a vent at some convenient point. Each furnace, consuming 500 horse-power, it is asserted, will produce in one day about 2½ tons of carbide.

The electrical equipment of the plant at Niagara consists of one 1,000 horse-power single-phase transformer and a reactive coil to be used in starting the furnaces, to prevent an overload on the generators; these are shown in the engraving, Fig. 2. There is also a 75 horse-power, two-phase, 2,000 volt motor used for operating the crushing, grinding and mixing machines, elevator and conveyors.

HIGH VOLTAGE LAMPS AND THEIR INFLUENCE IN CENTRAL STATION PRACTICE.—V.

BY G. L. ADDENBROOKE, M. I. E. E.

(Concluded.)

IT may be useful here to give a few general data relating to accumulators as they stand at present. The leading makers' prices of central station batteries work out at about £13 per kilowatt on a discharge for three hours, for the plates, cells and acid only; while, including stands, erection, connections and switching arrangements, the price works out about £17 per kilowatt, or, if buildings also are included, about £19 per kilowatt. In such a battery, I find the plates and lead cells alone would weigh about 8 cwt. per kilowatt output on the three hours' discharge basis; and that 1 cwt. of plates and cells costs a little under £2—or the cost comes to about £40 per ton. Now, as lead costs under £12 per ton at present, and seeing how much almost pure lead, in a very simple form, there is in accumulators, it does not seem unreasonable to anticipate that in the future, when accumulators are made on a much larger scale, we may see the price gradually come down to, say, £25 per ton, with, perhaps improved capacity and life. At least, it appears to me that there is as good hope in this direction as there is of reduction in price and improvement in quality in any other department of electrical engineering. If such a consummation were attained, it is pretty clear that it might pay to use accumulators for power stations, as well as lighting, wherever an eight or nine hours' day was in vogue, and that they may ultimately come to exercise a much wider influence on the future of the electric industry than most engineers have anticipated.

In order to gauge in some measure what has been the improvement in accumulators during the last few years, and since the question of the system of central-station supply was last prominently before this institution, I lately took an opportunity of talking the matter over with Mr. Epstein, and I asked him if by looking up old contracts and catalogues he could give anything definite on the subject; in reply, he has sent me the following letter: "I have looked into the question of the prices of accumulators, and I find that, comparing the prices of 1890 with the present ones, there is, on an average, a reduction of 25 per cent. But another and more important point is this—that whereas the types then manufactured were only allowed to be discharged in about ten hours, necessitating in the case of shorter discharges much larger batteries than required for the purpose, the discharge rate has since then increased very considerably. Taking one with the other, I think I am justified in saying that the reduction altogether amounts to quite 50 per cent." In view of these facts, and considering that it is now the custom to buy accumulators on a moderate maintenance agreement, and also all the added experience of

the last five years' work, it will be at once evident on how much sounder a basis commercially accumulators now rest, and how much stronger the arguments in favor of their employment in central stations are than they formerly were.

Upon the three hours' discharge basis, I find a kilowatt capacity of accumulators occupies approximately 4 cubic feet space, for the cells and connections, so that we get a kilowatt-hour into 1.33 cubic feet. Now a discharge of a kilowatt-hour, allowing for losses, will keep about fifteen 16 candle-power lamps going for one hour. Allowing that a gas burner using 6 feet of gas per hour is equal to a 16 candle-power lamp, the amount of space needed in a gasometer to store gas for the same amount of light is $6 \times 15 = 90$ cubic feet, or 70 times as much space. Of course, this is not quite a fair comparison, because nothing is allowed for stands, access, etc.; but I think it will be quite fair if we allow ten times as much space for access, etc., as the accumulators take themselves. Even under these, the actual conditions, accumulators only occupy one-seventh the space which the equivalent gasometer would. We arrive, therefore, at the curious conclusion that, if the London gasometers were emptied of their gas and fitted up as accumulator rooms, sufficient accumulators for lighting London could easily be arranged under working conditions in one-seventh of the space which would be available. We have, therefore, nothing very enormous to fear in the way of accumulator houses, even if accumulators are used in the future on the most extensive scale for lighting and power purposes.

Interesting as these speculations are, it is desirable, however, to return to what is more specifically our subject. It is usual at present to place the accumulators in the central station, except in a few instances, such as in Mr. King's system at Chelsea, Mr. Parker's Oxford system, and a few special places. Usually under these circumstances the accumulator is subject to the heavy drop at full load, which decreases its efficiency by 10 to 15 per cent. With 20 volt lamps the drop on the feeders within a mile radius would be much less than is usual now, and therefore the value of the accumulators would be correspondingly increased. For longer distances from central stations than a mile, however, undoubtedly the right place in most cases for accumulators will be at the feeder points. This is the more feasible with 220 volt lamps than under present practice, because the distributing network is so much larger from each feeder, and each feeder becomes the center of a serious amount of lighting, which will pay for individual attention. Although from the table I have given the cost of copper per lamp installed for feeders is very moderate, yet on a two-mile feeder it amounts to a considerable sum in the aggregate, and if, by installing accumulators at the end of the feeder for one-third to half the full output, the section of the feeder can be cut down by one-third or a half, a very important saving is effected; and, of course, if accumulators for two-thirds or three-fourths full load were installed, the cost of feeders would be correspondingly reduced. This has already been recognized in practice, and many devices have been brought out for charging accumulators in series, or by the help of motor transformers using a high-tension current; but I would point out that the use of 220 volt lamps on a three-wire system does away with the necessity for any of these complications. All that is needed is a continuous-current motor transformer of the "booster" type. In this, one armature circuit is across the mains, and wound with a high resistance and many turns, while the current to the accumulators passes through the second circuit direct; the second circuit being wound with a few turns, so that the voltage of the main current in passing through the armature is raised, say, 30 per cent. The motor transformer then need only be about one-third the capacity for the charging current, and the cells can be charged at any time, while the circuit is supplying lamps, so that continuity of supply without complication is ensured. By these means the cost of long feeders would be much reduced on the figures given above; which means also that it would be practicable to extend the lighting radius much further than was contemplated above at the same cost, should it be needed. An important factor is also brought in—that, having once laid a feeder of fair size, accumulators can be added at the outer end as the lighting grows, and thus a very large increase of lighting could be gradually met without relaying the feeder or disturbing the streets, which is always an expensive and troublesome operation.

In what I have said above I have indicated a feeder to each half square mile as an average, or four to the square mile; but it is clear that, if accumulators were employed, and it were desirable to concentrate them in order to save labor and attendance, it would be very simple to run short sub-feeders from a center, so that one distributing point where accumulators were situated, and one feeder from the central station, could be economically made to serve a square mile or more.

It is further worth noting that at 220 volts the cutting in or out of a cell makes less than 1 per cent. difference in the voltage, and not 2 per cent., as at present. This is an important consideration in keeping the light steady, a point the importance of which is becoming more and more recognized.

The convenience of the system for arc lighting does not need pointing out, as nine arc lamps can be run in series. One more point is the effect which a general electric supply at 220 volts on the lines indicated above would have on the power supply question. There is no difficulty in procuring already motors of any size, from 50 watts upward, to run on 220 volt circuits, the number of amperes they take being, of course, half what is usual now; while for larger sizes, say, above 3 or 4 kilowatts, they could, of course, be coupled across the two outers at 440 volts. If we then add the facts that the drop on the feeders would be less than at present, that the current density in the distributing system on the basis I have laid down would only be about half what it is at present—and when we consider that there would only be 1½ per cent. fall of pressure at full load on the distributing mains, and that by cross-coupling even this would be reduced—then it seems to me that it goes almost without saying that motors could be used to a far greater extent than at present is possible without appreciably affecting the regularity of the lighting. Accumulators at the feeding points would also be an important aid in this respect; if they were so used, the fall of voltage from them to the motors would rarely exceed 2 per cent., and under such circumstances motors of considerable size could be started and stopped (even without special starting resistances) without the rush of current being perceptible on neighboring lamps. In this respect, therefore, the use of 220 volts is likely to be very advantageous, and do away with the necessity of having to lay special power mains—for some years, at any rate.

The utility of having generators in the lighting stations giving the current and voltage which is needed for tramway work is also obvious; in fact, it looks as if one station in future would do all the power supply for a town, the lighting being only one adjunct of its business, and that, possibly, not the largest. With most of the lighting done by means of accumulators charged during the night, and the station supplying power to the tramways, etc., during the day, it ought to be possible to secure a very fairly even all-day load with one set of plant, instead of two as at present. This would, of course, lead to important economies in generating expenses. In fact, it looks as if we could already see far enough ahead practically to enable Mr. Preece's prophecy to be fulfilled in a moderate time—"that the electric light would ultimately be the light of the poor man as well as of the rich."

And now I must conclude. The title of my paper was "High-Voltage Lamps, and their Influence on Central Station Practice." In the first place, I have endeavored to show that high-voltage lamps are thoroughly practical. Next, that high-voltage lamps are more desirable than lamps of the usual voltage and of high economy. I have also shown reasons why it is probable that the economy of high-voltage lamps may in time nearly approach that obtainable in ordinary voltage lamps.

Having thus tried to establish the soundness of the position of the high-voltage lamp itself, I went on to consider what influence the adoption of a high-voltage lamp would have on central station practice. I have shown how it simplifies and renders less costly the distribution of current, and how it improves the conditions of lighting. I think I have further made it fairly clear that for nearly all practical requirements of town lighting the direct supply system will prove simpler and less costly, as well as more advantageous, than any system, whether direct or alternating, in which transformers are used; in fact, the necessity for this class of apparatus, except for special cases, seems to vanish.

I think, therefore, that when the facts are fairly faced, there does not seem much doubt that those engineers who have advised their clients to erect continuous-current direct supply stations in the past have done wisely, and will be found to have served their clients' best interests; and that for the future alternating-current stations, even for country towns and scattered districts, should only be erected after the most careful weighing of possibilities.

It is considerations of this character which have led me to keep very much in the background as regards central station lighting for the last four years. Having been associated from the early days with alternating currents, my predilections were in that direction; and although the position seemed secure, yet, seeing the possibility of great improvements in several directions which would tell strongly in the favor of direct supply (but the exact advent of which no one could actually foretell until it arrived), it seemed to me more prudent to turn one's attention to other things for the time than to incur the risk of recommending work which might soon have to be undone. I have always expected and looked forward to a time when there would be one system of lighting, with varia-

tions merely in details, and have felt that the rivalry between the two systems would some day end as the battle of the gauges ended in the early railway days, and I think there are signs of the end now. It seems as if the narrow gauge would win again—as if the tortoise would again beat the hare, though it is true that to do so the tortoise has had to improve its pace considerably.

REPORT OF COMMITTEE ON DATA.[1]

Your committee is able to present a tabulated statement of watt-hours produced per pound of coal from 82 central stations using coal as fuel, and from one using crude oil, and are able to show the class of equipment from all, boiler tests from 32, and engine efficiency from 8. So far the work has been carried forward on the lines of the previous reports by this committee. In addition to this, we have been able, from the information furnished, to construct load lines from 22 of the stations reported, the lines being presented on Charts 1, 2 and 3, submitted herewith, each line being numbered to correspond with the number of the report. Economies are given from a number of the largest electric stations in the country, 5 of them

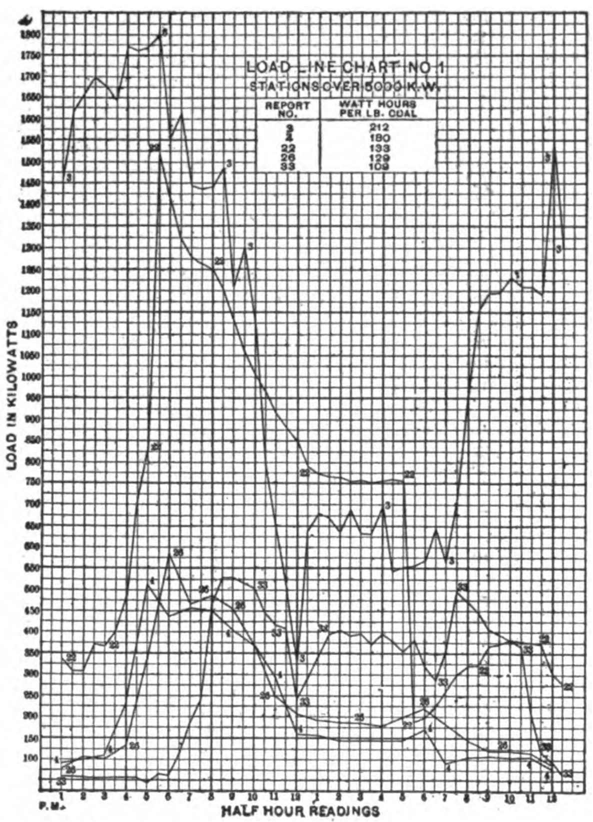

CHART No. 1.

having an output of over 10,000,000 watt-hours per day, and 45 having an output of 1 to 10 million watt-hours per day. Four of the large stations represent a production of 94,270 kilowatt-hours and a consumption of 524,667 pounds of coal, or 179 watt-hours per pound of coal. The aggregate output of these 49 large stations reaches the production of 212,617 kilowatt-hours in one day at an expense of 1,316,703 pounds of coal, or an average of 161 watt-hours per pound of coal. The aggregate output of 32 smaller stations, those producing less than 1 million watt-hours per day, represents a production of 11,973 kilowatt-hours with an expenditure of 194,274 pounds of coal, or 62 watt-hours per pound of coal. The aggregate electrical output of entire report, several stations having reported for a long period, in one case (Report 6) for one year, represents the generation of 4,618,976 kilowatt-hours at an expense of 28,-274,536 pounds of coal, or an average of 164 watt-hours per pound of coal. The average efficiency of the 81 reports using coal as fuel is 108 watt-hours per pound of coal; one report giving the production from crude oil shows 1,717 watt-hours per gallon of oil.

[1]Presented at the N. E. L. A. Convention New York, May 5-7, 1896.

The load lines shown in the charts have been constructed from thirty-minute readings from meters or estimated from voltage and amperes. The committee realize that in the case of alternating currents the product of amperes times volts may

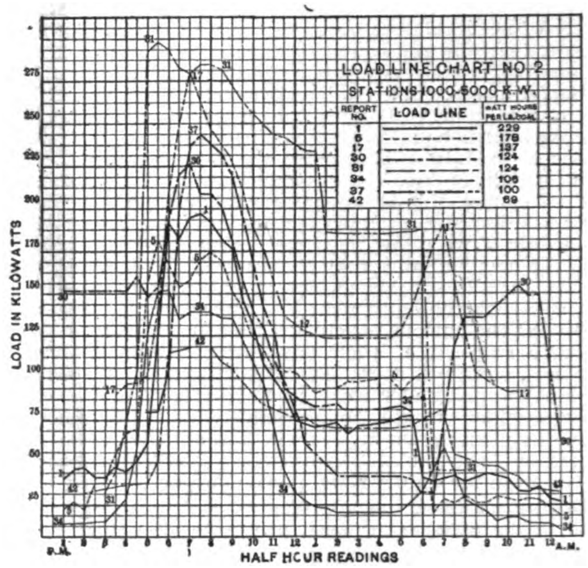

CHART No. 2.

not give the absolute watts, but this method has been considered sufficiently accurate for this work, and has been used in a few instances. The minor points called for in the information blank sent out by the committee relative to evaporation per pound of coal, water used in the engines, calorimeter tests, etc., have not received very general attention, although simple directions were given for this work. The 31 stations

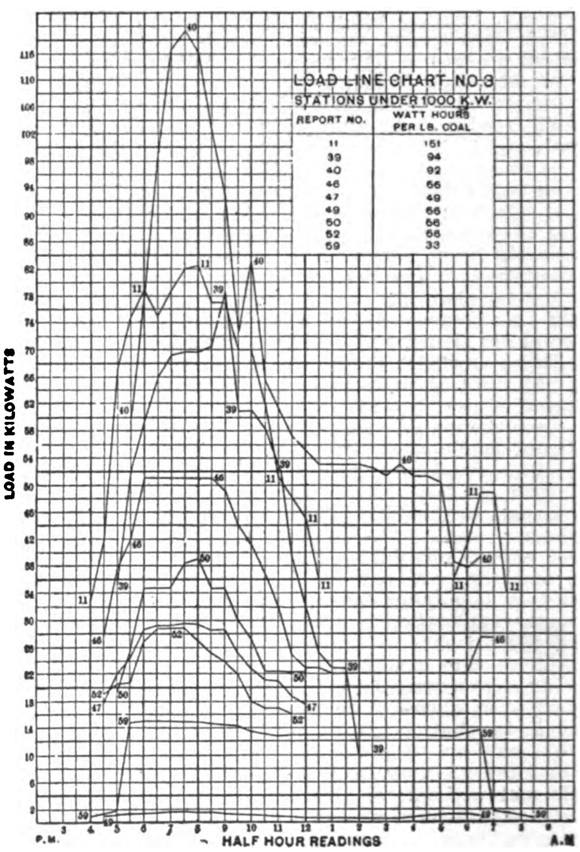

CHART No. 3.

reporting the water evaporated per pound of coal show a wide range of boiler efficiency not to be accounted for by the difference in quality of fuel. Report No. 81 evaporates 10.5 pounds of water per pound of semi-bituminous coal, comparing fav-

orably with report No. 8, each using horizontal tubular boilers; while report 67 evaporates only 4.66 pounds of water per reports being 7.09. In engine efficiency 8 stations report the water consumption per indicated horse-power. The triple ex-

NOTES.—1, 2, 3; See Load Line Chart 1, 2 or 3, the load line bearing the same [number as report.
4; Average from one year's record.
5; Total for one month.
6; Per gallon of oil.

Equipment Letters denote classes as follows:

A. Engines, triple expansion condensing. Boilers, horizontal water tube. Dynamos, multipolar on engine shaft.
B. Engines, Corliss compound condensing. Boilers, vertical water tube. Dynamos, bipolar, belted from jack shaft.
C. Engines, simple Corliss, or slow speed condensing. Boilers, horizontal tubular. Dynamos, continuous current.
D. Engines, high speed compound condensing, belted direct to dynamo.
E. Engines, simple high speed condensing, belted direct to dynamo,
x. Any of the above non-condensing.
y. Belted to dynamos.
z. Dynamo on engine shaft.

pound of bituminous coal with the same style of boilers. The average evaporation per pound of coal from all stations giving pansions lead in economy, report 80 showing a consumption of 15½ pounds, and report 3 showing 18 pounds of water per

indicated horse-power; these comparing reasonably with report 29 where an indicated horse-power is produced by non-condensing engines with 26 pounds of water. Report No. 22 in the Table of Economies submitted at the last convention, showing a production of 262 watts per pound of coal, and having the highest economy in the stations mentioned in that report, is from the same station as report No. 3 in the present table, and which in point of economy stands third on the last, the economy being 212 watts per pound of coal, a showing somewhat inferior to the previous report. The station is reported in a general way as running at greater economy than when the previous report was made. The efficiency figures, however, would seem to contradict this statement and to verify the statement in the present report. In the previous report, 9.37 pounds of water were evaporated per pound of combustible and 17 pounds of water consumed in the engines per horse-power. The present report brings the evaporation per pound of combustible down to 8.81 pounds of water, and the steam consumption in the engines is raised to 18 pounds, which would account for the lower efficiency stated in the present report.

Attention is called to the reports from plants running with non-condensing engines, in which report 26 (see load line) is able to show 129 watt-hours per pound of coal; report 32 (see load line), 113 watt-hours; report 33, 109 watt-hours; report 37 (see load line), 100 watt-hours, and report 38, 95 watt-hours. While Nos. 39 (see load line), 43, 59 (see load line), 68 and 71 running condensing produce respectively only 94, 68, 33, 78 and 87 watt-hours; this showing and other features in the report proving conclusively that it is as much a question of management and manipulation as of the type of machinery used.

In conclusion, we are led to repeat a former statement by this committee that the economy secured in generating power for electrical work does not compare favorably with the production of power for other purposes, and that this is also true after taking into consideration the variation in load due to electrical work. Referring to a recent statement of the economy of the Chestnut Hill pumping station, at Boston, it was found that in actual water lifted a horse-power was produced by the consumption of 1.34 pounds of coal; allowing that the efficiency of pumps compares favorably with efficiency of the generators, and making no allowance for variation in load, one pound of anthracite coal used with the same economy in electrical work should produce 557 watt-hours. Our load line charts show a fair average of the variation in electrical work, line 3, chart 1, dropping from 1,800 kilowatts at 6 p. m. to 250 kilowatts at midnight; yet the changes seem, as generally true in electric lighting, to be fairly uniform, and a station planned with the proper units for the work should operate the much larger percentage of its generating appliances of a fair basis of economy, bringing the record in this work much nearer the standard of efficiency in other lines. We advise more careful records, more frequent tests of all apparatus and a steady application of principles of economy until this record can be made to show more favorable comparison.

EVOLUTION OF INTERIOR CONDUITS FROM THE ELECTRICAL STANDPOINT.[1]—II.

BY LUTHER STIERINGER, M. I. E. E.

The users of conduits having a lining of insulation, in order to be consistent, should place only bare copper conductors within them. There is only one insulated iron tube, however, in use at present in which such a practice is carried out. This is for underground purposes. A recent installation at Niagara Falls is one of the latest examples of this system. The requirement for insulation of interior conductors is five megohms per mile. In view of this, it can hardly be said that a tube is "insulated" in a commercial sense when, if subjected to the tests applied to conductors, it deteriorates to such an extent as to be practically of no value. Such insulation in conduits is, on its face, of no value whatever to the conductor, which for its efficiency must depend entirely on its own insulation.

Although a period of fifteen years has elapsed since the introduction of the incandescent light, it cannot be said that a standard system of wiring, having the elements of permanency to recommend it, has yet been adopted. Cleat, knob, molding, and other makeshift methods, are still resorted to. Similar makeshift practices were in use in the early gas and water installations, such as the placing of the conductors on the outside of walls and ceilings. The concealment and proper placement of such conductors brought about a comprehensive standard of practice that is now nearly universal.

Conduits, when properly devised to protect insulated electric conductors placed within them from mechanical and chemical injury, make such protection absolute, and are accepted by all intelligent architects, engineers and constructors as permanent. Such a conduit, to be practicable, must be a pipe, or tube, of injury-resisting material; as, for instance, iron gas pipe, which has proved its durability in other more hazardous systems of distribution. The cardinal principle covering all conductors is that they must not allow leaks. The insulation on an electrical conductor, if possessing the property of resisting injury and deterioration, might be considered as self-sufficient. No such insulation, however, has been, or is likely to be, developed. There is one other embryo system that may be developed, possessed of sufficiently desirable features to yet become a standard and a rival of the conduit for interior distribution, viz., the solid, or fixed, system, in which the conductors are firmly fixed in position with the insulation in an injury-resisting metal tube, or covering. These can be made of any length, to suit all requirements.

Another form of a solid system is seen in the cable largely in use abroad for underground work. Its lead covering preserves the insulation, and the metal armor prevents mechanical injury. It has been suggested that this cable could be made sufficiently flexible to be installed from outlet to junction and junction to service. There certainly are situations where it can be employed to advantage.

Some years ago what is known as the concentric wiring system was introduced in England, where it is now in extensive use. "In this system the central conductors must be surrounded over their insulation by a metallic sheathing of conductivity equal to or greater than the core." The concentric system has not been employed in this country, although leading electrical engineers have long ago indorsed its practicability and usefulness.

A company recently put on the market an iron tube (gas pipe) with a lining of thin paper impregnated with an insulating compound, claiming for it the same values in insulating that were possessed by thicker paper-lined tubes already marketed, and also claiming the further advantage of a large bore with the same outside diameter of tube. This concern was absorbed by a company manufacturing the heavy paper-lined iron conduit, and since this consolidation the thin-lined tube has disappeared from the market.

An interior electric conduit of steel, thinner than ordinary gas pipe, with brazed seams, is being introduced. It is undoubtedly intended to be lined with paper similar to the iron-pipe conduits now made by several firms. The special advantage claimed for this steel tube is its cheapness. A large amount of similar tube has been in use for various purposes for some time. Experiments are now being made by various parties with steel and mild steel tubes of injury-resisting qualities and in special forms and fittings, with the idea that they can be produced at a cost lower than gas pipe, and, if found necessary, can be coated or lined with insulations of any kind or thickness.

Iron pipe coated with rubber and other compounds has been in more or less general use for gas and water services for many years. These tubes were coated principally for the purpose of preventing oxidation. The present practice in the case of gas and water mains, whether large or small, including all cast iron pipe used in plumbing, is to immerse the same in a hot bath of bituminous material, for the purpose of preventing escape of gases and oxidation. Such a coating in interior conduits would produce a smooth surface which may be of value, and at the same time cheap and serviceable. So far as the insulation of interior electric conduits is concerned, however, dependence must be placed in any and every case on the covering of the conductor, and not on the lining of the conduit. There need be no restriction as to the kind of material from which interior conduits are made, provided they conform to the requirements of perfect protection against mechanical and chemical injury to the conductors. Such protection was urged in 1890 by the National Electric Light Association at the Montreal meeting, and has since been insisted on by the National Board of Fire Underwriters, and still more recently at the conference on the amending of the national code of rules for safe wiring of buildings, held at the headquarters of the American Institute of Electrical Engineers in New York, March 20, 1896. At this conference the consensus of opinion which has been emphatically expressed by several delegates of large experience was tersely summed up by one of the members in the following brief sentences: "The reason for a lining in the interior of iron pipe must be either mechanical or electrical; if it is simply mechanical, it is inexpensive. If the reason is electrical, is it not rather anomalous that, in a city like this, you can have 100 miles of pipe in the street in which the insulated wires lie in a bare grounded tube, whereas the moment you go into a house you must not have it?" These

[1]Read before the N. E. L. A. New York May 5, 6 and 7, 1896.

requirements need only intelligent interpretation and enforcement to secure satisfactory results. As there is no outward pressure on conduits for electric uses, the same can be made in a simpler and less costly manner than the metal tubes now marketed, and yet possess all the requisite injury-resisting qualities. As soon as this fact is appreciated by manufacturers, evolution will produce the same beneficial results in respect to lessening the cost of material as was the case with wrought iron pipe, which has been tremendously cheapened within the past few years through use of improved methods. The adaptability of material to a purpose is well illustrated in the use of iron pipe in the pipe lines from the oil regions to the seaboard, a distance of over 500 miles. These have been in use for many years under enormous pressures, and give perfect satisfaction. On the other hand, all the resources of the United States Government could not provide a masonry conduit that would answer the purposes or stand the tests to which the above mentioned iron-pipe lines are daily subjected.

Professor Silvanus P. Thompson, in his concise and forcible statement made before the Society of Arts, on May 5, 1893, with reference to house wiring, said: "What is wanted is a mode of running the wires and fixing the switches and other accessories, that they shall not only be electric-tight, but shall be water-tight, gas-tight, air-tight, oil-tight, and rat-tight." All of the above requirements, and more, are fulfilled by a properly insulated conductor inclosed in an injury-resisting metal pipe.

In one of the recent installations of one of the large buildings on Broadway, New York, the electrical engineer who made the plans, firmly believing in plain iron pipe, called for it in the specifications submitted to the contractors. The argument used in introducing insulated iron tube, which was afterward installed, was that the insulation did no harm. If this insulation did not cost more than an iron pipe, or a coated iron pipe, that argument might be proper; but the fact is that architects and contractors find it difficult to have their clients agree to this additional expense. If it is not essential, it obviously suggests extravagance in engineering that is not warranted.

It has been said by an eminent engineer: "Proper engineering consists in utilizing no more material than is required to give satisfactory results." Any additional cost may benefit to a large extent those who seek to market their goods at the expense of a business which would have a more rapid growth if unnecessary cost could be avoided. We are all interested in the promotion of what is at once the cheapest and the best.

APPENDIX.

"House Wiring for Electric Light." Patent No. 343,087, granted June 1, 1886, known as Distribution and Control. No suit has ever been brought on this patent, although it has become the standard system of wiring. The company owning the patent has apparently contributed it to public use in order to advance the introduction of its interior conduits.

Extracts from the specification:

"The object in view is to produce a system of wiring houses, vessels, or the interior of other structures for incandescent electric lamps, arranged in multiple arc or multiple series, wherein there will be a complete and independent control and protection of all the circuits, so that they can be separately made and broken for turning on and off the lights, and properly inspected and tested for 'grounds,' cross connections or imperfect insulation or contacts, and so that the danger of injury by the heating of the conductors will be entirely obviated by the protection of both poles of each circuit by fusible safety catches, wherever a smaller conductor branches from a larger one; all this with the smallest possible number of switches and safety catches. The conductors will be of the minimum size and cost, reducing the expense of installation. There will be the minimum number of changes in the size of conductors, so as to simplify greatly the calculations of sizes of conductors and the preparation of proper plans, and to render the work easy of execution by workmen of ordinary intelligence.

"There will be a proper and equal distribution of current upon the conductors and to the lamps, maintaining all the lamps at normal incandescence, practically independent of lamps in other circuits, or divisions of the same circuit, and not taking any conductor unduly or beyond a safe current-carrying limit, and there will be a convenient location of switches and safety catches for the operation of the switches for testing circuits, for repairs and for replacement of safety catches. In general, the System of House Wiring may be stated to be a System of Distribution and Control, as distinguished from the System of Circulation heretofore employed. In the latter system the main conductors are run past all 'outlets' or points where the wires run into fixtures and the branch lamp circuits are taken from the main conductors at all points along their length, and are run by the shortest paths from the outlets to the mains. The general principle of the System of Distribution and Control is to take all branch circuits from each pair of main conductors at one point, and, if necessary, to divide a pair of branch conductors to all sub-branches from the branch conductors at one point, and so on to any extent of sub-division that it may be found desirable to carry the wiring.

"The conductors of each main are protected at the machine or machines or at the street connections (if in a general system), by double pole safety catches, and are controlled by switches which are also preferably double pole, and at each point of departure of branch conductors from the mains or of sub-branches from branches, each circuit is protected by a double pole safety catch, and controlled by a double pole switch, and the several safety catches and switches for each point of departure of branches from the mains or sub-mains or sub-branches, from branches are assembled together.

"The system hertofore employed has many practical disadvantages and defects, which are overcome and obviated by this system of distribution.

"The features of the invention are applicable to house wiring, whether the wires are concealed or are carried along the surface of walls and ceilings, but while exposed work may be done imperfectly and more expensively by a system of circulation, it is practically impossible to do 'concealed' work in this way, and provide accessible switches and safety catches for all the circuits, and hence the invention has special advantages in its application to concealed work."

A careful study of the patent from which these extracts are quoted may furnish useful information to the electrical engineer.

Extract from a paper read by W. J. Jenks, before the World's Fair Insurance Congress, at the World's Columbian Exposition in 1893:

"It is evident that if conductors are to be capable of ready removal for inspection or replacement, they must be so well insulated from each other and from the tube with which they may be surrounded as to resist the tendency to leakage or short circuit which is produced by the pressure of the particular system to which they are applied. Frequently difficulties arise from the disturbance of such tubes by carpenters, masons, gas fitters and other mechanics, who make changes in the surroundings after the tubes have been placed. Is there not a suggestion of a cheap and useful form of conduit for this work in the fact that for ten years or more the metal pipe of fixtures carrying electric lamps have supported and mechanically protected the wires by which these lamps have been fed? We have only to consider how the portion of the interior conduiting system which can be removably inclosed can be extended from the short length, from the lamps back to the service or junction of the interior conductors with the underground or overhead distributing wires, for which extension of the fixture pipes from the ceiling outlet to the point of supply of the building would provide. Can it not be presumed that, if by closing the upper end of the fixture stem with a water-tight plug we have been able for the past ten years to keep the inclosed wires running through that pipe in good condition, so that they have neither short-circuited between themselves nor grounded upon the fixture metal, we can make an entire system of distributing tubes of gas pipes without encountering serious engineering difficulties?"

THE HEATING AND VENTILATING OF THE SIEGEL-COOPER STORE.

In our recent description of the electrical equipment of the great Siegel-Cooper store mention should have been made that the heating and ventilating plant was carried out according to the designs and plans of Mr. A. R. Wolff, consulting engineer.

TROUBLE WITH THE TACOMA CITY PLANT.

Owing apparently to politcs in city affairs, there has been a good deal of trouble recently in the Tacoma city lighting plant, wires being cut and men refusing to work.

A SALT LAKE CITY TRANSMISSION.

President Donnellan, of the Big Cottonwood Power Company, Salt Lake City, has just entertained a large party there to celebrate the near completion of the power-transmission enterprise, planned by Mr. R. M. Jones, the details of which have already appeared in the columns of The Electrical Engineer.

CONTENTS.

COAL CONSUMPTION IN CENTRAL STATIONS.

FOR several years past the Committee on Data of the National Electric Light Association has submitted its report at the conventions, but notwithstanding the evidently earnest work and desire of the committee to give the association a valuable comparative document, their efforts can hardly be said to have been crowned with success. The blame for this must be laid on shoulders entirely outside of the committee itself and must be brought home directly to the door of central station managers. It is one thing for a committee to send out elaborate blanks to be filled out, and another thing to have these blanks properly filled and returned. It is, indeed, a sad thing to contemplate that, of some 2,700 central stations operating in the United States at the present time, the statistics of only 82 should be available, and that among these barely a score are given in the desired fullness. This is, indeed, a poor showing, and is in itself a sufficient explanation of the reason why so many stations are operating at low economy—the fact being that probably not one station manager in twenty is aware of the manner in which his apparatus is running. Admittedly unsatisfactory as the report is, it, nevertheless, indicates in a small degree what has been accomplished in some of the best stations in the country, and to that extent is of much value as recording standards for other stations to work up to. In glancing over the table one is struck as much by the diversity in the figures of boiler economy, as by that in those of the engines, even in what may be considered large stations, and in which, it may be presumed, competent supervision ought to be provided. In both cases the question of management is probably a large factor in the equation of economy. This is well brought out in the report, which dwells on the fact that in some instances stations running non-condensing are operating at higher economy than those having condensing engines. The committee might have been specific and added that the discrepancy here shown is probably due to the injudicious selection of the size of units, which works more to the disadvantage of the compound than of the simple engine. Regarding the future work of the Committee on Data, we must reluctantly agree with its spokesman at the convention in his expressed view that the results accomplished are not commensurate with the time and trouble spent on the collection and tabulation of the data. A good suggestion, however, was made, namely, that the work be hereafter confined to the collating and analysis of data of a certain number of stations of each type. This plan would limit the size of the undertaking and would still permit of comparisons being made and of the tracing of the causes leading to the results obtained. These test stations would thus, after a period, constitute a set of models, as it were, towards which similarly equipped stations ought to work—or which it would be well to shun.

PUCK'S "FORTY MINUTE" GIRDLE.

NOT until the cable has been laid across the Pacific will the telegraph be able to accomplish Puck's prediction that he would put a girdle round about the earth in forty minutes; but the experts at the National Electrical Exposition came pretty near doing it on Saturday night by sending to Tokio and back and to the tip of South America and back in 47½ and 21 minutes, respectively. It was a great night for the Western Union, Postal and Commercial Cable Companies, and none that saw it will ever forget the spectacle when the salvos of cheers from more than 10,000 people in that brilliant hall lifted Thomas A. Edison to his feet twice to receive their spontaneous and unstinted homage.

THE FEATURE OF THE EXPOSITION.

THERE is one feature of the exposition that must strike all observers in any degree familiar with the electrical situation, and that is, the courage and success with which what are known as the "independent manufacturers" have practically monopolized the show. Leaving out of view the superb exhibit of the local Edison Company, which, of course, includes a great deal of General Electric apparatus, and leaving out also the excellent exhibits of the Brush and Westinghouse Companies, it might fairly be said that the exposition owes its magnitude and importance very largely to the splendid displays of concerns that belong to no trust or combine, but depend upon the merit of their goods for public favor and patronage. In reality this exposition thus indicates the relative degrees of present prosperity and future activity as between the debt-burdened, tottering monopoly and the swarm of numerous energetic companies that are specializing their goods and capturing the market.

It is now recognized that one company after another has gone into the embrace of the General Electric Company simply to be gutted, leaving free for new enterprises a mass of talent and experience which is soon in service for new capital and in its own behalf. Thus a few "inside" stockholders are benefited, but the General Company has won nothing tangible. It is obvious that fifty or sixty millions of capital in the electrical business cannot be kept intact on a turnover of only some fifteen millions a year. Even a turnover equal to the bloated capital would barely pay dividends on it, and who expects ever to see the General Company do half that amount of business?

To be brief, the field belongs to the independent manufacturer, and we know of no power of purse, litigation or strategy that can deprive them of the great and grand market of electrical applications already established or now opening up.

220 VOLT INCANDESCENT LAMPS.

THE discussions at the recent meeting of the National Electric Light Asociation took in a wide range of sugjects, but, as we have had occasion to remark before in referring to the convention, the incandescent lamp was passed over with scarcely a mention. This is all the more to be regretted since recent developments in this field would have furnished an excellent topic for discussion. We refer to the steadily increasing use of 220 volt incandescent lamps. From the results thus far attained, the inference is fair that with the lapse of time their employment will cause the general displacement of the time-honored 110 volt lamp. The effect of the introduction of the high voltage lamp on existing circuits is admirably set forth in the exhaustive paper of Mr. G. L. Addenbrooke, concluded in this week's isue; but, in order to more fully comprehend the nature of the new departure, it may not be amiss to point out the fact that at the same efficiency, a 200 volt lamp must have a filament four times the resistance of a 110 volt lamp, and with the same surface. This means a very long and very thin filament, and such filaments are at once difficult to make and hard to support in the bulb, owing to their great length and lack of stiffness. Regarding the efficiency of such lamps, the fact must not be lost sight of that owing to their extreme thinness, these filaments are much shorter lived than the thicker 110 volt filaments at the same efficiency; and in order to render them commercially useful they are drawn to consume four watts per candle. This lower efficiency makes the filament thicker, besides lowering its temperature of operation. These relations seem bound to exist in lamps made by the present methods, using hydrocarbon treatment, and any improvement which produces a good 3-watt 220 volt lamp will probably make a corresponding improvement in the practical efficiency of the 110 volt lamp. The advantages of 220 volt lamps, from an engineering point of of view, are pretty well recognized; but it seems to us that Mr. Addenbrooke over-estimates them somewhat by basing his calculations on a constant percentage of loss in conductors, which in the example selected by him makes the same size conductor carry twice as much current for 220 volt lamps as for 110 volt lamps. Objections have been raised in some quarters to the introduction of 220 volts into fixtures, but with increasing use and with experience, these will be overcome without doubt. Inquiry develops the fact that during the past year one company alone sold 10,000 240 volt lamps, and that their quality is constantly improving so that as good results are obtained in practice from a 240 volt lamp as from the 3.1 watt, 110 volt lamp.

THE FERTILITY OF ELECTRICAL INVENTORS.

THE fine exhibit of electrical models made by the U. S. Patent Office at the exposition attracts large crowds, while it is no uncommon thing to see well-known engineers and experts hanging over the cases by the hour. Some of them meet with an occasional surprise, as did Mr. Westinghouse, when he came accidentally upon a telephone system which he invented as long ago as 1879. Some people who thought his electrical knowledge of late acquisition are as surprised as he.

But what impresses one in these interesting cases is the fertility of the leading electrical inventors. It has indeed been a glorious field for opportunities of work, and hence the leaders in electricity are likewise the leaders over all. The figures recently compiled by the U. S. Patent Office to show how things stood in this respect, are remarkable. We find Edison credited with 711 patents, taken out at the rate of 28 a year; Elihu Thomson with 394; Edward Weston with 274; C. J. Van Depoele with 244; and C. E. Scribner with 248. These men and their inventions respresent wellnigh all branches of the electrical arts, and are closely followed by others high on the roll of fame.

And yet, as one looks around the show and on the industry at large, one realizes that new big groups of inventions are needed, and that in all probability new names will be associated with them. There is room for the younger men and the triumphs of their seniors should stimulate them.

STEAM AND ELECTRIC LOCOMOTIVES.

NUMEROUS writers have discussed the probabilities of the adoption of electric locomotives on steam railway trunk lines, but all of these discussions have thus far treated the subject in a general way, and no detailed figures have been forthcoming by which a fair judgment might be formed of the real practicability of the proposition. In the articles by Mr. William Baxter, Jr., which have appeared in these columns, that writer has for the first time undertaken to show by direct comparison of item with item the true status of the situation, basing his arguments on the official reports of steam railway companies. In this week's issue Mr. Baxter undertakes to show that in the case of the Pennsylvania Railroad, that company could effect a saving of over $6,700,000, or 16.4 per cent. of its operating expenses, by the adoption of electricity. Some of Mr. Baxter's figures will no doubt call forth criticism among steam railway engineers; but far from seeking to evade them, we know that Mr. Baxter would be pleased to have any such brought forward. A thorough ventilation of the subject will not, we believe, result disadvantageously to electricity.

ELECTRIC TRANSPORTATION.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—XII.

Wm. Baxter Jr.

THE next item in the cost of operating steam roads that would be reduced by the use of electricity is that of water supply for locomotives. As electric motors do not use water no supply would be required and therefore the whole of this expense could be saved.

The next item in order is that of all other supplies to locomotives, and this includes oil, waste, packing for stuffing boxes, etc. As there are probably twenty times as many parts that require lubrication on a locomotive as on an electric motor, and as some of these parts, such as the cylinders, for example, require a large amount of lubricant, it is quite evident that the amount of oil used to lubricate locomotives would far exceed that required for motors. As to waste the same statement holds good. Locomotives are wiped off every day, but motors not once a week, and then the difference between the amount of surface to be cleaned in both cases is very great. As to packing, there would be none required for electric motors. In view of these facts it will not be unreasonable to cut down this item fully 75 per cent.

Now we come to the two last items, and we will consider them together because the change in methods of operating a road by electricity that would reduce the amount of one would also reduce the other. As will be noticed these two items cover the wages of switchmen, flagmen, watchmen, telegraph operators and train dispatchers, and also other expenses in connection with the telegraph system. We assume that these charges include the cost of operating the signal system, and on that account claim that the amount can be reduced by the adoption of electricity. To effect a reduction in these charges it would be necessary to replace the block system now used by an automatic one, in which the motion of all the motors on the road would be controlled one by the other, in such a manner as to render collisions practically impossible. We have already explained this system in a general way; it is not necessary to go into a detailed description, as several such systems have been devised and some have been worked out so as to meet every possible case that may arise in practice. Therefore it cannot be said that we claim a reduction in the two items under consideration on the supposition that a new and perhaps impracticable system of guarding against accidents would have to be used. It is true that a new system would have to be used, and it is also true that such a system has not yet been proved a practical success by actual trial. But there are some things that are so self-evident that we know they will work perfectly before they are tried and their actual practical operation only serves to demonstrate the fact. This is one of those cases, and no doubt there are hundreds of electrical engineers who have thought out arrangements of this kind.

TABLE 15.

SAVING IN OPERATING EXPENSES OF PENNSYLVANIA RAILROAD BY SUBSTITUTING ELECTRICITY FOR STEAM.

	$	Per cent.	$
Repairs of roadway	2,844,126	20	568,825
Renewals of ties	806,661	20	161,332
Repairs of bridges, etc.............	389,597	5	19,479
Repairs of locomotives	2,896,735	85	2,462,224
Repairs, shop machinery, etc......	149,167	5	7,458
Wages of engineers and firemen...	3,222,974	36[1]	1,147,103
Fuel for locomotives	3,724,481	72*	2,689,713
Water supply for locomotives.....	264,840	100	264,840
All other supplies for locomotives...	236,616	75	177,462
Wages for switchmen, etc..........	1,017,118	5	50,855
Wages of telegraph operators, etc..	1,142,946	5	57,147
Total..................................			$7,606,438

A full description of this system would convince any one at all familiar with the subject that an automatic system such as here proposed is thoroughly practicable, but such a description cannot be given until the rights are properly secured.

What proportion of these two items could be saved by using the system here proposed cannot be determined accurately, as we have no way of ascertaining what portion is directly chargeable to the signaling system; but it is evident that by doing away with all the signal stations pure and simple, that is, those at which there are no switch levers to operate, a very considerable saving could be made. As we are practically without any data upon which to estimate the possible saving, we will make a very moderate claim. We know to a certainty that a saving could be made, and if we can save anything at all it ought to be at least five or ten per cent. We will restrict our claim, however, to the smaller percentage.

We will now summate what could be saved by the substitution of electricity for steam and thus determine whether the total amount is enough to justify the expenditure necessary to provide an electrical equipment.

From the above table we see that the sum total of all the savings that can be made by the adoption of electricity amounts to more than seven and a half millions of dollars, which is over eighteen and a half per cent. of the total operating expenses. This looks like an enormous saving and will no doubt come as a surprise to those who have only counted on making a reduction in the coal bill. It seems almost impossible that such a saving could be made. It may be well, therefore, to look over our reasoning once more and see whether we have assumed a saving in items in which a reduction cannot be reasonably expected.

The first three items, repairs to roadway, renewals of ties, and repair of bridges, may be open to dispute. It may be claimed that no saving could be made in this direction, and although reasoning on correct theoretical principles would lead to the inevitable conclusion that the repairs to the structures would be reduced by the use of electric motors and the consequent elimination of the violent vibrations caused by locomotives, we will concede that there may be room for doubt as to whether the saving would be as large as here claimed. In fact, to see how we will come out by making an extremely conservative estimate, we will admit that nothing can be saved in these items. As to repairs to locomotives we would not be willing to make any such concessions for the very simple reason that, as was clearly shown in the discussion of this question, seventy per cent. of these repairs is on parts that are not used at all in electric motors, and the remaining thirty per cent. is on the machinery of the locomotive. It seems impossible that the wear on the motors should be even as much as one half what it is on the corresponding parts of a locomotive; and that is the relation that was allowed in claiming a reduction of eighty-five per cent. Therefore, we will have to insist, even though willing to make every reasonable concession, that the saving in this item is not any more than practice would bear out.

The repairs to shop machinery and tools is a debatable question and we will therefore strike it out, although there can be no doubt that it would be reduced, from the very fact that there would be less repair work to do. The reduction in wages of firemen could not be changed, as it can be effected if motor cars are used instead of locomotives, and there is no good reason why they should not be used.

The saving in fuel is another item which will not admit of any reduction. A careful consideration of all we have said on that point will show that it has already been made as small as possible. Of the remaining items the only ones in which there is any room for argument are the last two, which cover the wages of switchmen, flagmen, watchmen, telegraph operators, etc. These we can drop out of our claim of savings. Adding together these items that may be conceded to be more or less doubtful we will have:

Repairs to roadway	$568,825.26
Renewal of ties	161,332.38
Repairs of bridges	19,479.89
Repair of shop machinery, etc.........	7,458.35
Wages of switchmen, etc...............	50,855.94
Wages of telegraph operators, etc......	57,147.30
Total	$865,099.12

We thus see that by throwing out entirely those items in which there is room for a reasonable doubt, we still are able to show a saving of $6,741,343.12, which is nearly 16.4 per cent. of the operating expenses.

Inasmuch as we have gone over our figures a second time and have pointed out those items that would be struck out wholly or in part, in an ultra conservative estimate, it is only fair that we should go over them again and see whether there are not some other items in which we could be justified in claiming a saving if we were determined to make the best possible showing for electricity.

[1] Approximately.

In following out this course, if we look at the charges under the heading of maintenance of way and structures, we will find that the cost of renewing rails has not been included in the list of items in which a reduction could be effected. But it will be apparent at once that if the smooth motion of a train drawn by electric motors, and particularly the smooth motion of the motor car itself, will tend to reduce the wear on the roadbed and ties, it will have the same effect on the rails. As a matter of fact it should have, if anything, a greater effect. A locomotive does not move in a straight line parallel with the rails, but follows a wave-line course, due to the side strain caused by the unbalanced condition of the moving parts. This wave motion causes a lateral sliding of the wheels over the rails and thereby increases the wear. This action may not produce very noticeable effects, but, whatever it may amount to, it represents just so much wear that would not be produced by electric motors. It is evident, therefore, that in neglecting to make a reduction in this charge, we have failed to give electricity its full due.

In the matter of maintenance of equipment we have made no claim for a reduction of the cost of repairs of cars, and yet there are several reasons why we should. The more even motion of the motors would produce less strain on the couplings, and, in a measure, on the whole car, and this would necessarily reduce the wear. But this is not the principal cause that would tend to prevent deterioration. The effect of the smoke and cinders on the cars is a factor of considerable importance, especially with passenger cars, on which their action soon produces a dingy appearance, in consequence of which frequent repainting is necessary. This, however, is not all; sometimes the cinders set fire to the cars and in this way considerable damage is done; although this does not happen very often, it is no doubt of sufficiently common occurrence to have a considerable effect on the total cost of repairs.

This brief allusion to some of the causes of wear and tear on cars that are due to the action of the locomotive and would be eliminated by the substitution of electricity will serve to show that, in justice to the latter, we should have made a reduction in this item, but did not do so from a desire to confine our claims to thos charges in which a saving is self-evident and of such a character as to be estimated with a fair degree of accuracy.

Under the head of conducting transportation we find that the largest charge is that for wages of trainmen. We have not claimed that the adoption of electricity would reduce this item, but it undoubtedly would. We may also add that no reduction was made in the wages of enginemen, the reduction in that item being only the wages of firemen. But to be fair we should claim a reduction in wages of enginemen and trainmen. The reasons for this, briefly stated, are, that a motor car could make more miles per day than a locomotive, therefore a smaller number would be required to make the same yearly mileage, and consequently the total wages of enginemen would be reduced. This would be true if the present rates of speed were maintained, but as it would undoubtedly be found that increased speed in all classes of traffic would be more economical, a still further reduction could be made.

As there have been a great many conflicting statements published as to the daily runs of locomotives, and several attempts made by friends of the latter to show that a locomotive can make as great a mileage as an electric motor, it may be well to show just what is done in actual practice.

On the Pennsylvania Railroad there are 1,103 freight engines, and the total miles run by freight trains per year is 20,400,358. It is evident that these locomotives are not in use all the time, as a certain number will always be in the shops undergoing repairs. Assuming that only ninety per cent. are in constant use, we would find that the average number of miles run per year by an engine would be about 20,500. If twenty per cent. of the locomotives are in the repair shop on an average, then the yearly mileage would be about 23,100. In the passenger service there are 478 locomotives, and the total miles run per year by passenger trains is 14,908,800. Figuring on a basis of ninety per cent. of the engines in use, the miles run per year would be 34,670, and on an eighty per cent. basis, 39,000 miles per year.

Trolley cars making an average speed of less than ten miles per hour run from 45,000 to 50,000 miles per year. At this rate motor cars drawing freight trains at 15 miles per hour could easily cover 65,000 to 75,000 miles per year, and those used for passenger work and making an average speed of 30 miles per hour, could run over 100,000 miles per year. Now, if so much greater yearly mileage could be made by electric motors, it follows that the wages of motormen would be very much less than the wages of enginemen per train mile, as the daily compensation would certainly not be any higher, and the miles covered would be much greater. Therefore, from this cause, the reduction in the item of wages of enginemen and firemen would be even greater than we have claimed.

As to trainmen, the reduction in wages per train mile would probably be very small or none at all, if the present rates of speed were maintained; but as has been shown, an increase in speed could be made in all classes of work without any material increase in running expenses. This cannot be done with steam, because the repairs, and especially those on locomotives, increase very fast with augmentation of speed. The reduction in wages of trainmen per mile run would more than make up for any increase in cost of coal and repairs, even for a considerable increase in velocity; therefore, by adopting a somewhat higher speed a considerable saving could be made, and not only that, but with the same equipment, more work could be performed.

In view of all these facts it is evident that our estimate is very conservative and that the results shown could be fully realized in practice.

The saving, as shown, does not represent the net result, as from this amount must be deducted the wages of employés in the power stations and linemen required to keep the trolley lines and feeders in repair. The cost of fuel consumed in stations would not be deducted from this saving, as that has been included in the calculations just made.

We will, in the article to follow, give an estimate of the capacity and cost of installation of an electric equipment for the Pennsylvania road, and in connection with this estimate will show the number of employés required as linemen and stationmen, and the total amount of their wages. We will then be able to show the net difference in cost of operating the roads by steam and electricity, and also the cost of changing to the latter system.

AN UNDERTAKER'S WAGON LIGHTED BY ELECTRICITY.

William J. Tickner & Sons, undertakers, have purchased a novel design in the way of an undertaker's wagon. It was used for the first time a few days ago. The wagon is lighted by electricity by means of a storage battery under the seat. The wagon is drawn by two pure-white horses.

NEWS FROM LOS ANGELES.

The electric road from Los Angeles to Santa Monica Beach, a distance of 20 miles, has been opened for traffic, and upon the following Sunday the company sold several thousand round-trip tickets. It was impossible to accommodate the crowds. People were riding on tops of cars and on trucks, and even standing room was at a premium.

Mr. Herman Laguna, who secured the franchise for the telephone company in Los Angeles some nine months ago, has his agents on the ground contracting for instruments, and claims he will start things a-moving inside of sixty days.

THE BIG B. & O. ELECTRIC LOCOMOTIVES.

The last of the three great electric locomotives for the operation of all trains on the main line of the Baltimore and Ohio Railway has been shipped from the Schenectady works of the General Electric Company. These locomotives will handle the entire freight and passenger traffic of the Baltimore and Ohio Road passing in and out of Baltimore from the north through the Belt Line Tunnel which passes under the city, and which is the longest soft earth tunnel in the world. Each of these locomotives weighs 96 tons, and while almost equal in size to the largest steam locomotives, greatly exceed them in power—that of each equaling nearly 1,500 horse-power. The first was put into service in August last and the second in December, since which date they have been handling the entire freight traffic of the Baltimore and Ohio through the tunnel without accident of any kind.

No limit of speed has yet been reached with these engines. Eighty miles an hour has been attained.

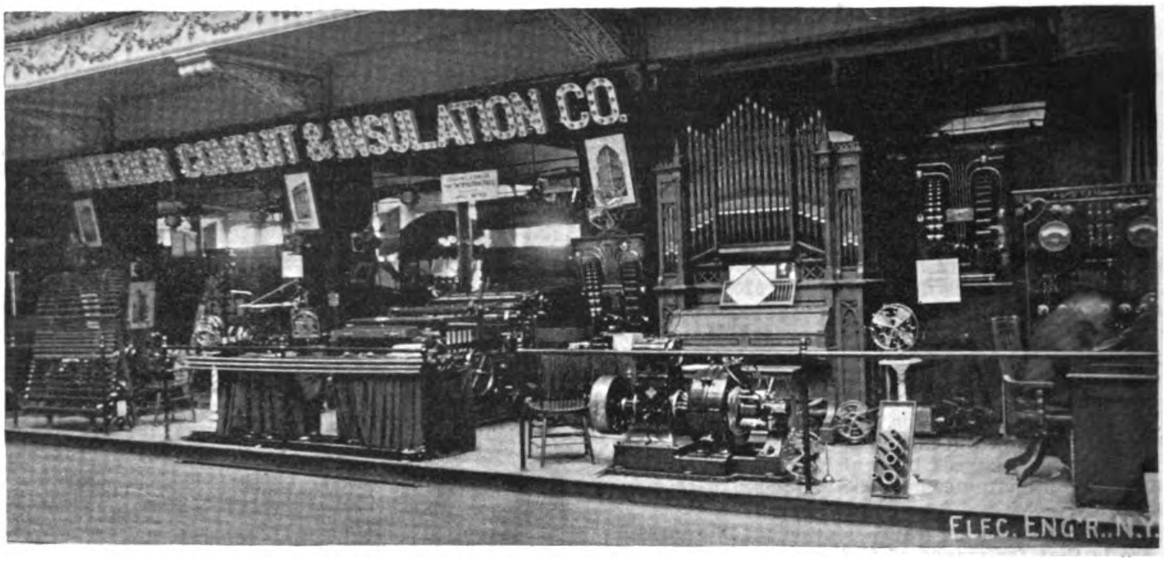
As soon as the third locomotive reaches Baltimore it will be assembled and placed on the tracks. They will then undertake the passenger service as well as the freight traffic, and the present coke-burning engines used with the passenger trains running through the tunnel will be shut off before entering the tunnel.

THE ORDER for the wire for the new electric railway in course of construction between Elgin and Geneva, Ill., has been secured by Holmes, Booth & Hayden, Waterbury, Conn., through their Western agent, Mr. M. B. Austin, the whole amounting in the aggregate to some 125,000 pounds. The Ohio Brass Company have closed the order for the overhead material and tools for the same line through their Chicago agent, Mr. J. H. McGill.

Exhibition Notes—II.

THE INTERIOR CONDUIT AND INSULATION CO.'S REMARKABLE EXHIBIT.

PERHAPS it was not generally realized until this exposition what a remarkable variety of goods and apparatus is turned out by the Interior Conduit and Insulation Company. The space occupied by the Company is almost the whole of Section E, and covers nearly the entire north side of the main hall. It is filled with products that touch all the various branches of the art, and there are few concerns that could begin to make so varied a display. Reflecting credit on the management of the company for its enterprise and energy, the goods tell a remarkable story also of inventive ability and of effective factory skill and vigilance.



THE INTERIOR CONDUIT AND INSULATION CO.'S EXHIBIT AT THE ELECTRICAL EXPOSITION.

It would be difficult to enumerate all the noteworthy appliances and pieces of apparatus included in this extraordinarily fine exhibit. There is, of course, a complete collection of all the types of interior conduit, down to the last, with junction boxes, etc.; and with these are associated many special features such as the interior conduit system adapted to underground work for all classes of wires. Johnson double pole switches are there also, with couplings and other details. It is not to be forgotten that the company had meantime been working out a very successful sectional underground trolley system, in regard to which there are many inquiries made at the show.

Turning to the generating apparatus, we find a direct connected Lundell plant for marine purposes in particular, and driven by a Case engine. Nothing could well be more compact. Then there is a fine display of Lundell motors standing by themselves, and one of them running a small generator of the same general type. A great variety of machinery is in operation driven by Lundell motors, from an S. S. White dental outfit up to a Cottrell printing press. In the central space is a fine one-half manual pedal base Liszt organ with 20 stops, from Mason & Hamlin, operated by the Lundell organ blowing outfit. When Mr. Vandewater, of the company's executive staff, who is a well-known composer and musician, is induced to take the console, a treat is given that delights hundreds of people; while the easy flexibility of the method is clearly shown at the same time.

As for ceiling fans, electrolier fans, desk fans, etc., of the famous Lundell spherical type, their name is legion, for they are not only to be seen within the space, but all over the building, "a boon and a blessing to men." One of these motors has the honor of having been the first to receive Niagara power in New York City. The Western Union circuits were being adjusted and balanced for the Tesla two-phase system, when, in order to ascertain if there was much current on the line, a little Lundell was picked up and hitched on. It was running free, without load, but gave at once unmistakable evidence of the fact that Niagara was literally and actually doing work in New York City, 465 miles away. The motor has been fittingly embellished to commemorate the occasion.

The exhibit is in charge of Mr. Kimber, but Messrs. Johnson, Bakewell, Pease, Lundell and others are all frequently present. They have no reason to be other than very proud of their record at the exposition, and the exhibit must undoubtedly do the company great good.

EXHIBIT OF THE WESTINGHOUSE ELECTRIC MFG. CO.

IT would not have been easy for the Westinghouse Company to have put one of their big Niagara generators on the main floor of the exposition, but they secure just as great an effect with the public by their little Tesla two-phase motor running the Niagara model by Niagara energy. In fact, it may here be said again, that none of the exhibits run to bigness, but are all highly representative.

The current from Niagara for the motor is reduced in pressure at the Falls to about 450 volts and transformed to three-phase by the Scott system. Two Western Union wires and the earth circuit are used, Mr. A. S. Brown, the electrical engineer of the Western Union Telegraph Company, having assisted in the plans and arrangements. The line distance is 465 miles. At the New York end, the voltage is reduced to 12 volts and transformed into two-phase by highly efficient converters.

In order to give the public a clear idea of the action of the Tesla rotating field, a ring of iron has been wound with coils in the two-phase relation. In the strong external rotating fields, copper plated eggs, gyroscopes, rings, discs and other metal bodies are set waltzing in a manner that interests the student and greatly tickles the sensation hunter.

THE WESTINGHOUSE EXHIBIT.

Practical applications of the Tesla two-phase principle are given by several two-phase motors, a Shallenberger meter, and single-phase self-starting motors. Among other things in the space are the new Westinghouse fan motor, a standard switchboard panel, switches, Wurts' lightning arresters, etc. The exhibit is in charge of Mr. Arthur Zimmerman, of New York,

and Mr. Malcolm Maclaren, of Pittsburg, who are indefatigable in their attentions and explanations to visitors. The space is topped by a large handsome red sign with incandescent lamp ornamentation.

THE EXHIBIT OF THE NEW YORK EDISON CO.

UNDER the active and intelligent supervision of Mr. R. R. Bowker himself, the New York Edison Company, over whose affairs he watches so vigilantly, has made an exhibit that evokes admiration from the public and expert electricians alike. It is not large, nor is it small. It is not ornate, but it is very handsome, and its regard for the sense of proportion is very pleasing. It is not a central station, nor is it a bazaar of electrical goods, yet it shows clearly what a central station can do and how the work is done; while at the same time it is surrounded and flanked by adjuncts which bring into proper prominence the various uses to which electricity can be put, ranging from a static machine at one end run by motor, an electrical piano and a cooking outfit, to a printing press at the other end.

THE NEW YORK EDISON ELECTRIC ILLUMINATING CO.'S EXHIBIT.

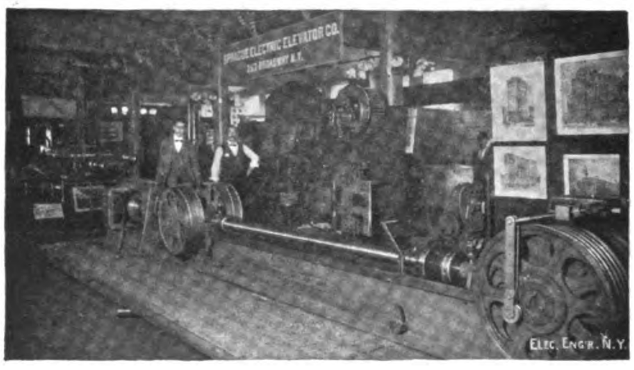
The exhibit lies along the whole southern side of the main hall. As the visitor enters from the stairway, he sees a clever representation in color, on canvas, of the great operating room in the central station at Duane, Elm and Pearl streets. Here are shown, as though in relief against the scenic background, actual sections of the Van Vleck edgewise regulating system, with dynamo switches, regulators, ampere and voltmeters, and with controlling apparatus feeder. Current for this exhibit is supplied to the feeder switchboard from the Edison street mains, and from a storage battery, illustrating the use of such batteries in Edison stations. From this switchboard the current passes through a feeder-tube, such as is used in the city streets, to a feeder-box, thence to a distributing-box, thence through a street main to a service-end box, such as is placed on a consumer's premises. Next the feeder-box is one of the new controllable boxes, by which a tie-feeder can be divided from the station into distributing feeders. From the service-end box, current is carried through an Edison chemical meter, such as is usually placed in a customer's premises (as also through a Thomson wattmeter) and is distributed as it would be in a house, from a distributing switchboard, for its varied applications in lighting (incandescent and arc), power, cooking, heating, etc. Two posts, similar to those on Fifth avenue, show the Edison-Bowker system of street lighting. Electric cooking is shown in practical operation, under the direction of Mrs. Sickels, who gives cooking lessons, as is also electric ironing; and electric heating is exhibited by ordinary radiators, by the "electrotherm" for bedwarming, poulticing, etc., and in other applications.

The power exhibit includes a modern printing press run by Card motor, under the supervision of Mr. R. T. Lozier, without belt or shafting; ventilating fans of various types; surgical and dental machinery; a sewing machine; the electric piano, etc. Elevators run by electric current are shown elsewhere in the building. The center of the exhibit is occupied by the huge curved frame of an upper field of one of the monster 800 k. w. dynamos in the Duane street station. On the map are representations of the principal stations of the Edison Company, which has now six stations, supplying 6,000 customers with over 300,000 incandescent and 3,700 arc lamps, and about 15,000 h. p. for power and miscellaneous purposes, forming the largest installation of any electric supply company in the world. Beyond this exhibit is a dark room in which is a joint exhibit of electric lamps manufactured by the General Electric Company and used by the Edison Company. This room illustrates various methods of lighting, including the latest plans for using reflected light, so that the lamps are not directly seen. There are some very clever theatrical and trophy effects in it. Electric signs and advertising specialties are also exhibited.

The whole space is railed, the posts carrying knobs in imitation of Edison lamps. The wiring, though "temporary," is very carefully and thoroughly done. It is enough to say that Messrs. Lieb, Van Vleck, Smith, Williams and other members of the company's well organized staff have planned the exhibit, laid it out, and given its operation their best thought and endeavor. A finer epitome of the central station art has never been shown.

DISPLAY OF SPRAGUE ELECTRIC ELEVATORS.

THE Sprague Electric Elevator Company have an exhibit in Section F, just back of the Interior Conduit Company, in which they group some of their latest and best machinery.



THE SPRAGUE ELECTRIC ELEVATOR EXHIBIT.

It is not material which lends itself to spectacular use, but there are a great many visitors to the show who appreciate its genuine importance, and who linger around the space to

study it. Mr. Frank J. Sprague is himself in constant attendance and much sought after. The exhibit comprises a multiple sheave elevator for passenger use in office buildings, etc.; a tandem and gear drum elevator, a house elevator, and a grouping of the regulators, switches and detail parts. A Sprague electric passenger elevator is also running in the building, able to carry a hundred people, and has been employed for all the distinguished guests. The worm and nut principle of the Sprague system has already been frequently described in our columns, and there is no need to go into details of it here. It may be added that a number of interesting modifications and special variations have been worked out.

THE GENERAL ELECTRIC EXHIBIT.

THOSE who are quizzically inclined at the show make good humored fun of the great General Electric Company, which has a neat display fronting on the Main Hall, the chief feature of which is a large frescoed background with a goddess of plenty in it. The average idea is that with less background of promise and more foreground of reality, the General Electric Company might have produced a better effect, for it is certain that the ordinary visitors to the show—and there are a great many of them—go away with the idea that the General Electric Company is one of the smaller concerns, whose chief business lies in the sale of a few pretty stage effects. The electrician knows better than this, of course, and knows that much of the adjoining exhibit of the New York Edison Company is to be regarded as an exposition of what the vast resources of the General Electric Company can do.

The space is neatly framed around with incandescent lamps, and includes standard and inclosed arcs as well, one or two fine electroliers being shown. There are also a number of smaller G. E. details, such as motors, meters, etc., and some bromide prints of apparatus and plants. Just off the space is a room containing a board at which one can switch on and off lamps of all sizes and voltages; and this is supplemented by some pretty shields, stage effects, etc. The whole has been tastefully arranged, and the "Brownie Room" in particular is crowded all the time.

THE GENERAL ELECTRIC CO.'S EXHIBIT AT THE ELECTRICAL EXPOSITION.

BORNE, SCRYMSER COMPANY, of New York, made a handsome display of oils suitable for dynamo, motor, cylinder, engine and machinery purposes. They supplied oil to a number of the exhibitors and in this way advertised their various products. Mr. Renshaw and Mr. J. H. Torrey were in charge of their exhibit and attended to the wants of all consumers.

"HABIRSHAW."

A STRONG personality tells anywhere, and when an individual reputation is built up by long years of success it takes a hold on the public mind that cannot be shaken off or

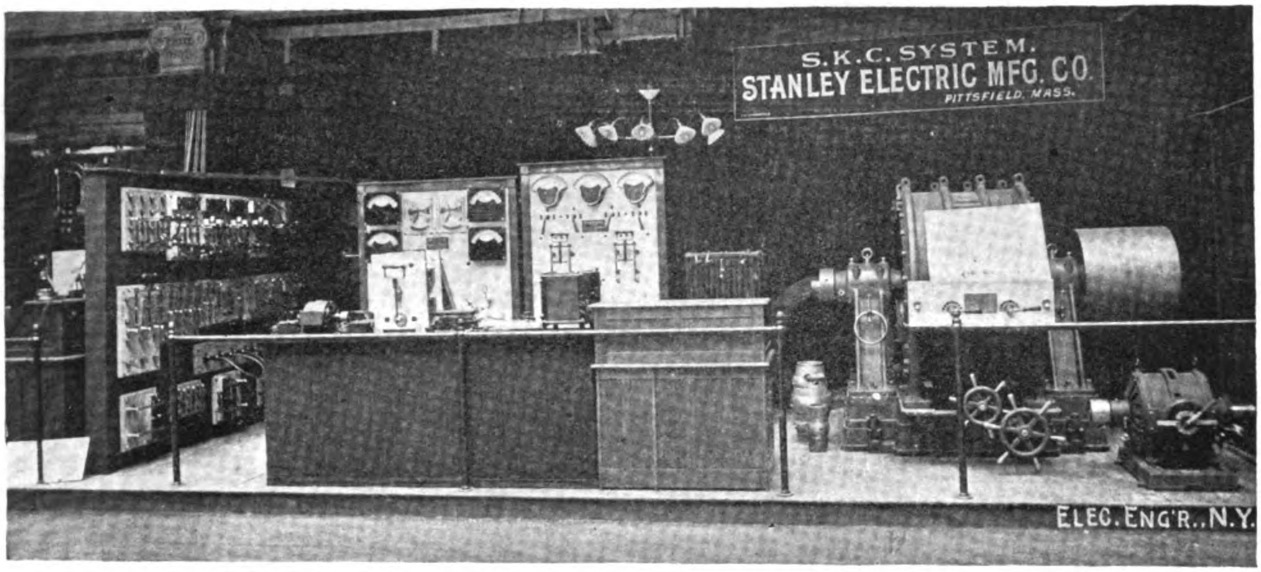
THE HABIRSHAW WIRE EXHIBIT.

disturbed. There are many fine wire and cable exhibits in the show, and it may be questioned whether a better grouping of them has ever been made before. Among these one of the most prominent and deservedly interesting is that of the India Rubber and Gutta Percha Insulating Company, of this city, who, true to their national colors, have their handsome booth effectively draped in red, white and blue, while the lamp "banners" on their "outer wall," bear in gleaming bands of light the universally-known name of Habirshaw. The booth, however, is not for mere display, but is business to the "core." Around it are reels of wire and cable, across its ends are sample boards; the central desk brims over with samples of Habirshaw products for all the purposes of telegraphy, telephony, electric lighting, electric power, etc. The exhibit also contains some very interesting examples, bare and covered, of the bars and cables made for the Niagara plant and power transmission, constituting some of the heaviest copper pieces

ever built. The exhibit is under the constant direction of Mr. J. W. Godfrey, general manager, associated with whom are Messrs. Harrington and Olsen, while Dr. Habirshaw himself is not an infrequent visitor on evenings when there is some chance of moving around with comfort.

THE EXHIBIT OF THE STANLEY ELECTRIC MFG. CO.

It is a fortunate thing that the Stanley Electric Manufacturing Company, of Pittsfield, decided to put a big machine in its space, for while it is a considerable strain on the floor, it typifies for the visitor the heavier class of apparatus not otherwise to be seen in the Main Hall, and gives an excellent idea of the degree of perfection reached in phase dynamos. It is indeed a beautiful machine, which finds admirers of its curves among the ladies who know very little of its intrinsic merits. Facing as it does on the Main Hall, one of the six exhibits that has the honor so to do, the Stanley Company enjoy considerable attention. The exhibit is excellently grouped. It includes not only the big 180 kilowatt generator, but single and two-phase motors, several Stanley transformers, switchboards and their equipment, measuring instruments, and a great variety of details, all showing care in production and beauty of finish. The exhibit was put in order under the direction of Mr. J. F. Kelly, who has also been in frequent attendance.



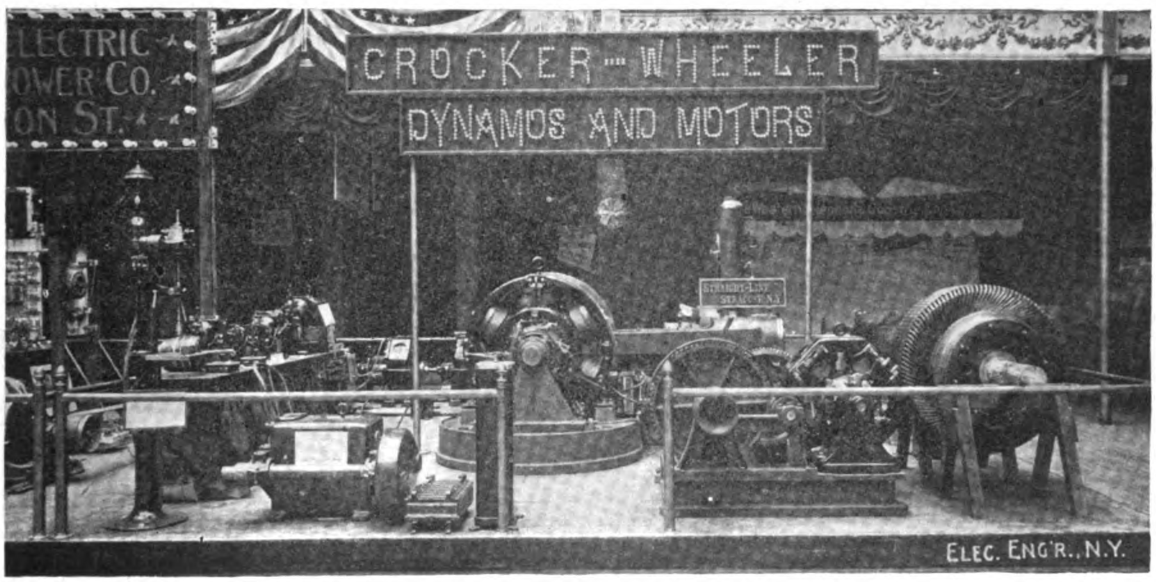
THE STANLEY ELECTRIC MANUFACTURING CO.'S EXHIBIT AT THE ELECTRICAL EXPOSITION.

FINE EXHIBIT BY THE CROCKER-WHEELER ELECTRIC CO.

SECTION L on the main floor is perhaps one of the most interesting and attractive of the exposition, both on account of the conspicuous place it occupies, and also because it embraces but three exhibits representing well known and progressive firms. One of these, near the main entrance, marked space 164, is occupied by the Crocker-Wheeler Electric Company, who have on exhibition a great variety of their products.

In the center of the display is a Straight Line engine directly coupled to a 56 kilowatt Crocker-Wheeler dynamo, compound wound, operated as a compound motor and driving the steam engine. An armature for a 250 horse-power dynamo and one for a 100 kilowatt direct connected machine attracts a great deal of attention, as does also the ironclad "mill motor," used for driving machinery in rolling mills. It is dust and water proof, and protected against mechanical injury. Such machinery will undoubtedly replace the steam engines used at present. The apparatus here is a 40 horse-power machine, and is used with an ingenious controller.

Motor dynamos transforming direct to alternating currents and 115 to 200 volts are shown, and a small motor is connected directly to the main shaft of a Prentice Tool Company two-

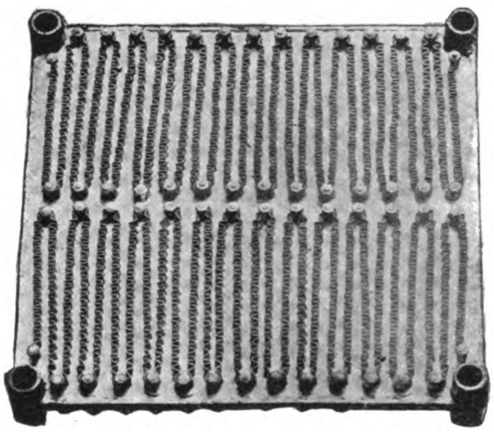


THE CROCKER-WHEELER ELECTRIC CO.'S EXHIBIT AT THE ELECTRICAL EXPOSITION.

speed sensitive drill. Small $^1/_{12}$ horse-power fan outfits with ball joints at the bases are in operation, and project the air at any desired angle. Besides these we see motor dynamos with automatic field cut-out, automatic brake motors for hoists, punch presses, etc.; a standard 230 volt, 3 horse-power motor, zigzag iron rheostats, the new automatic gravity drop starting box, which prevents a person from starting the motor should the current have been shut off from any cause without first putting in the starting resistance; also a 15 horse-power rotary transformer, with a primary of 115 and a secondary of 200 volts. A very instructive feature of the exhibit is the actual winding of small ⅛ horse-power and 65 horse-power elevator motor armatures by experienced men from the works at Ampere, N. J. It may be of interest to note that on the evening before the opening of the exposition a Crocker-Wheeler motor was run by the current brought from Niagara Falls, this being the first motor to operate machinery in the City of New York by that source of power. The following gentlemen are ready at all times to impart any desired information: Francis B. de Gress, Alfred D. Baldwin, H. D. Lufkin and Gano S. Dunn. Dr. Wheeler and Professor Crocker are also frequently present.

THE EXHIBIT OF CARPENTER AND LEONARD RHEOSTATS.

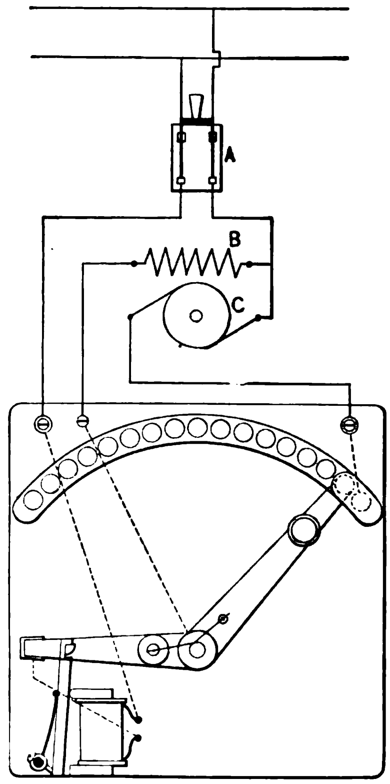
IN no branch of the electrical manufacturing arts has there been more real and rapid advance than in the construction of rheostats. When one remembers the huge, clumsy old contrivances, as big as a sentry box and as full of spiral wire as a spring bed, it is little short of amazing to find the same important functions of current regulation performed by a modest disc or slab no larger than a chair seat. Moreover, with the reduction in size and refinement in detail, has gone a lowering of price that is simply phenomenal. Rating efficiency against efficiency between old and new, it will be found that a modern rheostat can be bought for about 20 per cent. of the cost of three or four years ago.



Leonard Ribbon Rheostat.

There have been various workers in this field, but the fact that the Carpenter Enamel Rheostat Company, as represented by the Ward Leonard Electric Company, of Thirteenth and Washington streets, Hoboken, are the only exhibitors of rheostats in the exposition, is indicative of a good many things to the student of electrical industries. Messrs. Carpenter and Leonard are distinguished for having begun the reform in rheostat work and for having pushed it so far that they may be said to have literally created a new art. Their influence is felt abroad not less than here, for their goods go to every leading concern in Europe, while unsolicited orders pour in constantly from foreign houses.

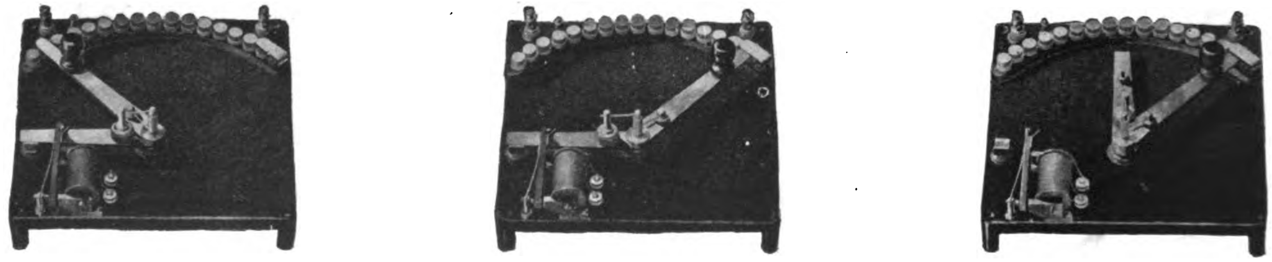
The Ward Leonard Company will hereafter be the representative before the public of the Carpenter Rheostat Company, whose goods it will market. It will introduce important new lines of apparatus based on existing methods, and will also rapidly develop new appliances due to the later inventions and patents of Mr. Leonard and Mr. Carpenter. As their highly interesting exhibit at the show proves, these two gentlemen have deliberately selected the field of heavy work upon which to concentrate their efforts more particularly, but they have had, owing to the demands on them, to bring out one or two specialties. The heating of air and water, however, as in the case of heating rooms, cooking, etc., they have let alone, believing that their work was most needed in what may, perhaps, be called "serious" work.



A.—Double Pole Switch.
B.—Motor Shunt Field.
C.—Motor Armature.

Diagram of Connections.

At the exposition, where they occupy Space 43, Section C, the Ward Leonard Company issue a new catalogue, which is in reality a clever and very valuable treatise on rheostats and their use. It contains a number of highly important tables, one notable feature of which is the evident scientific grading of the sizes, so that a purchaser can get his rheostat effects in any combination and degree best suited to his requirements. Hitherto, sizes and capacities have been widely and extravagantly apart, but with this catalogue in hand, any need can be economically filled.



Starting. Full Speed. Automatically Stopped.

Leonard Automatic Universal Rheostat.

The round type of Carpenter field rheostat is familiar, and a wide range is shown, while the classification in the catalogue is extensive and complete. The next item is a striking novelty, due to Mr. Leonard, and recently patented. It is an enamel

rheostat. of the appearance here indicated. It is well known that in earlier forms, fine wires have been embedded or laid flat in spirals in the enamel. There would seem to be, however, a limit to the capacity of the enamel to stand the sudden and frequent development of heat, and hence Mr. Leonard has devised a method in which thin metal ribbon is used, set in enamel, but standing out at right angles to the iron base-plate. Hence ensues an elasticity and radiation ability that is remarkable, while the general slight rise in temperature is also a very good quality. The ribbon is of special alloy, and does not appreciably deteriorate or oxidize. These Leonard enamel rheostats will take care of any large currents for heavy work.

The next novelty shown is the Leonard universal automatic rheostat, here illustrated in perspective and by diagram. Its quick action is a guarantee of protection against sudden overload of a motor or against the sudden cessation and return of current, or against the carelessness of the operator, or against practically any effect of current that would damage the machine.

The end aimed at is accomplished by one magnet placed in series with the entire motor current. This magnet consumes no appreciable amount of energy, and does not heat under any conditions to a detrimental degree, and does not affect the speed of the motor at all. In thus automatically opening the circuit to a shunt wound motor the main circuit is opened, but the shunt field, under all conditions, is kept connected upon the armature, the armature winding and field winding always form a closed circuit, and hence there is no field discharge and no sparking in opening the circuit.

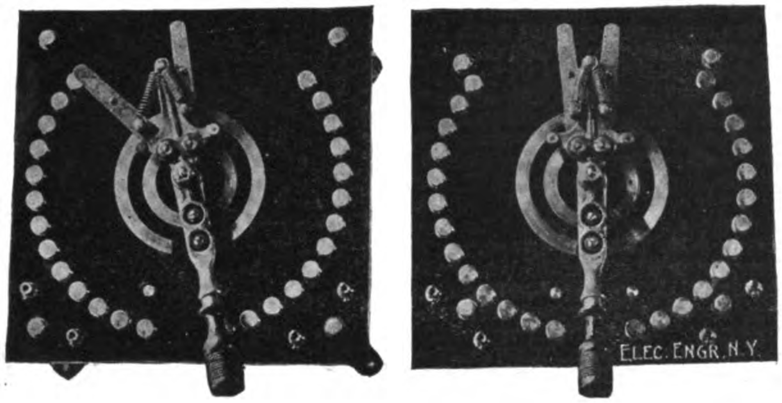
After the circuit is automatically opened it cannot be again closed, except by first inserting all the resistance of the rheostat, thus making it impossible to send an excessive current through the rheostat and motor. The rheostat contact lever has a spring always tending to insert the resistance. The lever cannot be left upon an intermediate contact. When the resistance is all cut out the lever is held by a friction clip. No carelessness on the part of the attendant or a stranger can possibly result in any damage. The arrangement of the magnet so as to perform its functions of safeguarding from each end of the armature is most ingenious and very prettily worked out. If anything wrong happens, the circuit has got to open.

Another neat piece of apparatus is the reversing controller, for motors ranging from ½ horse-power up to 100 horse-power. At the show one of the sizes can be seen in operation in the fine exhibit of the Niles Tool Works, and it may be here noted that hardly an exhibit of light and power in the building is without Carpenter rheostats on its armature or switchboards.

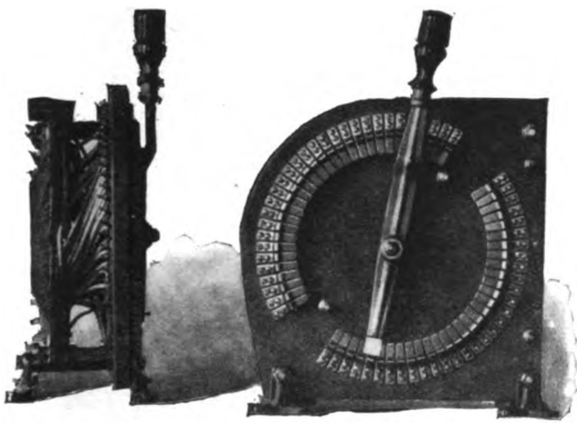
Theatre dimmers have of late years come to be an indispensable adjunct, and in the advertisement of the Ward Leonard Company in this issue of The Electrical Engineer a bank is shown as installed in the Star Theatre, New York. The details are as shown by the cut herewith. No fewer than 350 have been sold within the last nine months, and others since the opening of the show. The economy of space and the greater safety are incalculable.

Two minor pieces of apparatus seen in the exhibit at the show attract much attention from the public, namely, the Leonard flatiron and the Leonard soldering iron. In the former the concentration of heating effect is pushed to the utmost degree, but it finds a rival in the solderer, a large type of which is shown, intended for 500-volt street railway work. How a road can get along without such an appliance, it is difficult to imagine. There are a few other pieces of apparatus on view, but, as already said, though the enamel lends itself to many purposes, and though the company have sundry ingenious small appliances, it is the "heavy current" work that demands practically all their time and energy.

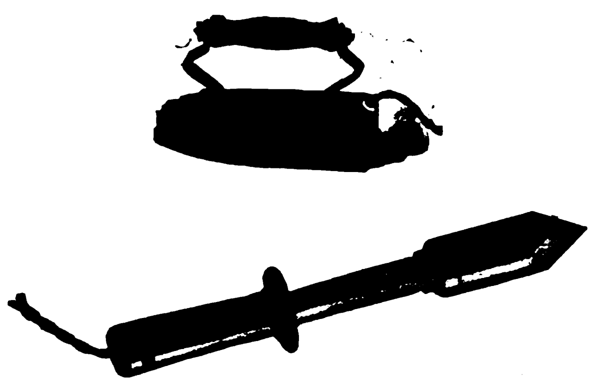
The catalogue, it may be noted in conclusion, contains a table of useful equivalents, by Mr. Leonard, for dealing with electric heating problems, and one due to Mr. Kennelly, giving ohmage, etc., for wires from No. 0000 down to No. 40, which runs 34,340 feet to the pound.



REVERSING CONTROLLERS.



THEATRE DIMMER.



LEONARD FLAT IRON AND SOLDERING IRON.

RUSSELL-SEE ELECTRICAL INDICATOR COMPANY.—The only exhibit of electric sidelights is that made by the Russell-See Electrical Indicator Company. Their booth represented, as it were, a ship at sea with sidelights burning, showing clearly the extended use to which their lights can be put in ships, locomotives, signal posts, etc. Their device consists of an ordinary cylindrical reflecting headlight, in which are contained two incandescent lamps, so connected that if one fails to burn the other will take its place and continue to burn and at the same time give notice of the change by means of an annunciator.

A CHOICE EXHIBIT BY THE BRUSH ELECTRIC CO.

"LIFE in the Old Dog Yet," might well be the sign hung up over the excellent exhibit made by the Brush Electric Company, of Cleveland, in the basement or generating plant. The exhibit occupies no less than 425 square feet, and is every inch of it solid with good apparatus. The space may be said to be divided into two parts, one devoted to the historical exhibit of the company and the other to the exhibit of their latest and most modern machinery. Mr. S. M. Hamill, general manager and vice-president, and Col. Rogers have both taken personal pride and pains in the arrangement, and have the pleasure of knowing that their efforts are appreciated daily by the public and by crowds of friends.

The historical exhibit consists of the Brush arc dynamo which was sold in 1877 to parties in Baltimore, who ran it for twelve years. Also a sixteen-light, 2,000 candle-power arc dynamo, which was run by the Fulton Worsted Mills, Fulton, N. Y., from September 1, 1879, to April 10, 1892, when it was secured for the exposition at the Columbia Exposition. Also a forty-light Brush arc dynamo, which was operated by the Berkeley Company, in Providence, R. I., from December 1, 1881, to May 19, 1893, when it was purchased for exhibit at the Columbian Exposition. These dynamos are exhibited just as they left the factory years ago. Not a bobbin or an armature has been rewound, or a shaft, wire or a commutator replaced.

The working exhibit consists of a new 80 light, 2,000 candle-power Brush arc dynamo connected to a 60 kilowatt, 200 volt motor. Eighty double Brush arc lamps hung gracefully around the exhibit are operated from the direct connected dynamo.

In connection with the direct connected 80 light dynamo is shown in practical operation a machine running with a load of eighty lights with a difference of potential not exceeding 1,500 volts between any part of the machine or circuits and the machine still maintaining its automatic regulation. To put it more plainly, these circuits are run direct from the terminals of the dynamo on any of which circuits the voltage does not exceed 1,500 volts, or, in other words, on any one of which circuits there are not more than twenty-seven 2,000 c. p. arc lights. This is an entirely new method of running on an arc dynamo and is exhibited for the first time in the Brush exhibit. It was devised and carefully worked out by Mr. C. M. Green, of the Brush testing department.

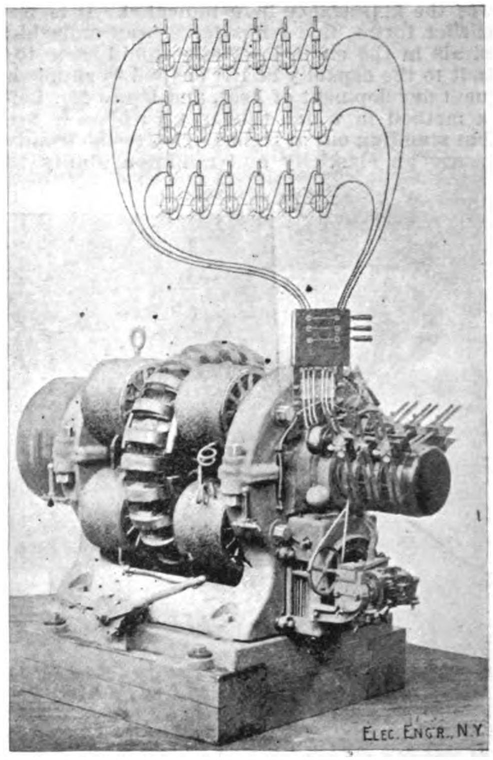


FIG. 1.—THE BRUSH, 3-CIRCUIT ARC DYNAMO.

There is also a 100 light, 2,000 candle-power Brush arc

FIG. 2.—THE BRUSH ELECTRIC COMPANY'S EXHIBIT.

dynamo and a 125 light, 2,000 candle-power Brush dynamo. These three large arc dynamos are of the very latest Brush type. They have been recently designed by the Brush company, who have already sold over 20,000 lights capacity of them.

A rack of the various styles of lamps which the Brush company manufacture is also exhibited.

EXHIBIT OF THE ELECTRIC STORAGE BATTERY CO. OF PHILADELPHIA.

As the development of the storage battery and its applications are of unbounded interest to the electrical engineer, as well as to the general public, its advantages having long been recognized, it is not at all surprising to see at all times an eager crowd surrounding the exhibit of the Electric Storage Battery Company, of Philadelphia. Their display in spaces 53-56, Section D, main floor, is one of the largest and best equipped of the exposition, as they do not simply show samples or models, but the actual pieces of apparatus, regardless of size and expense. We find here a battery of 128 Chloride accumulator cells, charged on the Edison 240 volt, three-wire circuit. They are charged directly through a motor booster of 90 volts; a complete controlling switchboard accompanies this outfit, containing Weston meters and Carpenter enamel rheostats.

A 21-foot electric launch occupies a prominent place in the center of the exhibit, the motor being exposed to view, also the battery racks. Adjoining this is the large type of central station cell of no less than 4,260 ampere-hours capacity.

Beside this stands an electric carriage, similar to the one which won the gold medal at Chicago. It is fitted up with a battery which will give it a maximum speed for thirty miles. The complete outfit weighs 1,700 pounds.

Besides these larger contrivances, portable batteries for fan motors, lamps and various other appliances are shown in generous quantity.

This splendid exhibit is in charge of the well-known authority on storage batteries, Mr. Charles Blizard, the general manager of the New York office.

THE ELECTRIC STORAGE BATTERY CO.'S EXHIBIT AT THE ELECTRICAL EXPOSITION, NEW YORK.

NOTES OF THE EXPOSITION.

During the week a set of Lieut. B. A. Fiske's range finding apparatus, intended for the new battleship "Iowa," has been added to the collection in the Loan Exhibit. It is complete with all the circuits, instruments, etc., and attracts great attention. It gives the range at two miles, with a possibility of error not exceeding 3 per cent.

The Electrical Luncheon which followed the cable-sending feats on Saturday night was served in a room in the roof garden, specially fitted up under the direction of Superintendent Nathan. It was a blaze of color, tastefully set off by plants and foliage. The electrical lighting effects were beautifully done by the decorative lamp department of the General Electric Company, under the planning of Mr. McAllister. The Birdsall Electric Manufacturing Company also contributed some choice pieces, including a bank of roses, etc., wired with lamps, a music box in circuit with the flowers, jardinières with lamps, cigar lighters, and other things that greatly interested everybody. The luncheon was served by the Murray Hill Hotel, and was cooked and warmed on the electrical apparatus loaned from the Edison exhibit. During the luncheon, the band played on an adjoining stage. After this agreeable interlude, Mr. Edison received the guests in his X-ray chamber, and gave them all an opportunity to inspect their own bones at the fluoroscope. The entertainment was given by the Exposition Company, to whom the credit is due for a most delightful experience.

A great many distinguished visitors have attended the show during the past week. Among them were the Corean Embassy; Donna Elvira de Bourbon, daughter of Don Carlos; Miss Sarah J. Farmer, daughter of the late Professor Farmer; various members of the Vanderbilt family, and practically all the fashionable contingent of New York society. The schools and

colleges have now begun to arrive, and last week saw several institutions represented, from Columbia College down. During the present week a great many others will be at the show.

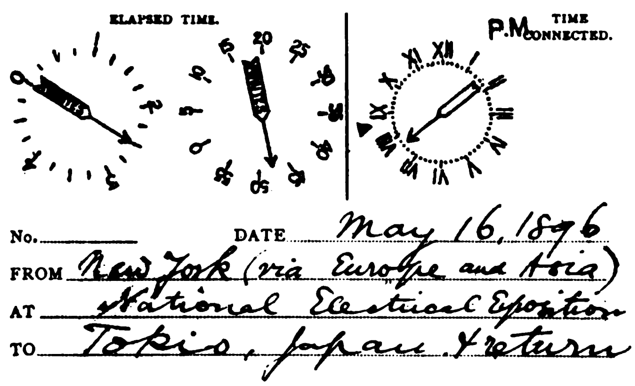
The Edison fluoroscope exhibit is a great drawing card. It is operated by Mr. Luther Stieringer, who has it under the care of Messrs. Fred Ott, Brown and Dally, from the laboratory, three tried and expert experimenters, who are not a little amused at their new experience in showing a delicate scientific discovery to thousands of people.

A lecture room for the display of X-ray slides, Geissler tubes, spectrum of the arc, etc., has been fitted up on the annex floor and is already a drawing card. Miss Crumbach, who has been helping in the Press Bureau, is the lecturer, and does her work well, Messrs. Stieringer and Osterberg having helped to equip her with the necessary stock of scientific popular talk.

Mr. G. E. Curtis, the photographer at Niagara Falls, N. Y., has sent to the exposition a magnificent series of views of the grand old Cataract, mounted. They have been grouped along the back of the Erie Canal exhibit and elicit unbounded admiration. Copies mounted or unmounted can be obtained from him at very reasonable prices. Better views of the Falls have never been taken.

KEEPING TAB ON THE ROUND-THE-WORLD MESSAGE.

IT occurred to Mr. Abbott, of the Calculagraph Company, that it might not be a bad idea to keep tab on the message to Tokio and back on Saturday night, and he accordingly did so. The card that went through the machine is reproduced herewith. It was noted at the time that a short fifty minutes



CALCULAGRAPH CARD USED FOR THE "ROUND THE WORLD" MESSAGE. TIME, 47½ MINUTES.

elapsed, but as there were many watches in use and none agreed, it was thought best by those who announced the news to be on the safe side. Mr. Abbott's forethought, however, secured the exact times and the exact duration, and the card herewith constitutes, therefore, part of the historical record.

GORDON-BURNHAM BATTERY EXHIBIT.

The Gordon-Burnham Battery Company, of New York, have an extremely interesting exhibit of their celebrated Gordon cell, which is largely used for open and closed circuit work. They have installed their exhibit in a tastefully decorated booth, and arranged the cells in pyramidal form. At intervals they have in circuit a few Geissler tubes, which serve to attract attention and fascinate the passers-by. Within the past few months the Gordon cell has made rapid strides and is now used on nearly every railroad in the United States for signal work. It has also become a prime favorite for telegraph, telephone and fire alarm work, besides all the usual domestic electric purposes. Mr. F. A. Burnham, general manager of the company, is in frequent attendance, but the exhibit is in charge of Mr. R. W. Gordon, vice-president, and W. C. Banks, electrician of the company.

HUGO REISINGER'S EXHIBIT.

Hugo Reisinger, of No. 38 Beaver street, New York City, is making a splendid exhibit of the celebrated "Electra" High Grade Nürnberg Carbons which he introduced into this country and which have become a prime favorite for constant potential and alternating current arc light.

The exhibit consists of carbons for direct and alternating current lighting, searchlight carbons and all kinds of carbons for telephone construction, batteries and smelting purposes.

We understand that the European factory of the "Electra" carbons is the oldest and by far the largest in Europe, and the carbons manufactured in the same have gained a world-wide reputation during the past ten years by their fine and uniform quality and high efficiency.

Two very interesting tables show the life of the "Electra" carbon as compared with others, and the weight of the dust produced by the various makes of imported and domestic carbons.

The booth, which is most tastefully decorated in white and gold, is much admired as being one of the handsomest at the exposition. Mr. John C. Outwater, who has charge of the electrical department, is in constant attendance, and his uniform courtesy in explaining the various diagrams has won many admirers. For an exhibit of carbons, Mr. Reisinger is to be congratulated upon imparting to it something of real live interest, and the exhibit has called forth much praise from many of the visitors.

EUGENE MUNSELL & CO.—The exhibit made by this company consists of large samples of block India and amber mica, also solid sheets of India mica segments, washers and mica for rheostats. The booth is very effectively decorated.

THE MICA INSULATOR CO.'S EXHIBIT.

THE MICA INSULATING CO. occupy the same booth as Eugene Munsell & Company, their exhibit consisting of a fine array of micanite segments, tubes, troughs, rings and plates. A striking feature of their exhibit is a large commutator made up of micanite, and also an armature made up of the same material.

THE BALL & WOOD CO. have in operation a 50 horsepower engine direct connected to a 100 kilowatt Siemens & Halske generator. The engine is equipped with the new Ball & Wood oiling system, gravity feed, dispensing entirely with the use of oil cups, and admitting of close inspection by the engineer while in use.

EXHIBIT OF THE NEW YORK CARBON WORKS.

NOT showy or sensational, but to the electrician and engineer very effective, is the snug exhibit of the New York Carbon Works along the north side of the main hall. Their display embraces all the leading specialties in carbon manufacture, with not a few lines in which they have made a distinctive reputation. Among the goods shown may be mentioned carbon discs or buttons, carbon granulated and carbon dust for microphones; carbon points for small apparatus needing contacts and non-sparking pieces. There are also carbon plates and cylinders for battery use, and a fine line of carbon brushes. The latter are of the type sold by the works to such roads as those of Chicago, the North Hudson County Company, the Brooklyn and Coney Island, and others.

The works also exhibit some fine carbons for arc lamps, which have been selected for many styles, and have now been adopted for the Nowotny lamp, to be seen also at the show. The carbon brushes are made in three qualities, soft, medium and hard, and run very smoothly and quietly. The lamp carbons are of equally high grade and are made to fit any requirement of current or voltage. The carbon plates are made from the best retort gas carbon, and are finished with much

precision and care. The range of cylinders and cups is large, for both open and closed types of primary battery.

At the show the works have been admirably represented by Messrs. G. W. Mills and H. N. Mills. The headquarters of the concern in New York City are at 39 and 41 Cortlandt street. The factory is located at Newark. The officers are J. S. Silver, president; Albert Storer, vice-president; W. H. H. James, secretary and treasurer, and G. W. Mills, general manager. In the absence of the latter well-known gentleman, who has been called away to close up some important orders, his son is taking excellent care of the exhibit.

THE EXHIBIT OF WOOLF'S ELECTROZONE.

IT would hardly be supposed that a very attractive exhibit could be made up out of electrolyzed salt water, but Mr. A. E. Woolf, with wonted taste and cleverness, has contrived to do it, and his space, No. 142 and 145, in Section H, immediately adjoining the historical and loan exhibit, and beautifully draped in yellow, etc., is one of the best, and always crowded. In the enclosure is a huge bottle, human size, of electrozone, and right in front lie framed extracts from the leading papers of America describing the use of this purifier and disinfectant at the New York water supply at Rikers Island of garbage; by the Philadelphia Board of Health, and elsewhere. Nearby are microscopes for showing the effect of electrozone when sprayed on living organisms in water. Supplemental to this are working models of the Woolf system of electrolytic bleaching, and the Woolf method of manufacturing chlorine and caustic soda by electrolysis. In fact, Mr. Woolf has the leading electro-chemical exhibit of the show, and is scoring heavily by his enterprise and by the fact that he is pushing

WOOLF'S ELECTROZONE EXHIBIT.

along a genuinely good thing. Besides the distribution of electrozone, he is giving away samples of "Meditrina," a concentrated solution to whose virtues in sea-sickness not a few who went to the last yacht races will testify.

MOORE'S "ARTIFICIAL DAYLIGHT" EXHIBIT.

During the convention of the National Electric Light Association, Mr. D. McF. Moore delivered a lecture to a crowded audience on his vacuum tube lighting. Since that time he has taken possession of a niche in the main flight of stairs, just off the main hall, where he has constructed an entirely inclosed booth. It is exteriorly draped in red and interiorly in white, and against the white background are placed a number of tubes, spirals, designs, etc., to illustrate the possible effects obtainable with his methods. It is only fair to say that this little modest room, where daylight is manufactured, and where Mr. Moore himself is often present as chief magician, is one of the most attractive and popular features of the exposition. Mr. Edison remarked laughingly that it was even drawing more people than the X-rays; and, as a matter of fact, as many as 2,500 people in a night have stood patiently in line in order to watch the cheery gleams of those long white tubes, "full of luminescent nothingness." Every visitor of distinction to the show has considered it his or her duty at least to see the Moore exhibit and then go away wondering over it.

EXHIBIT OF THE NATIONAL CARBON CO.

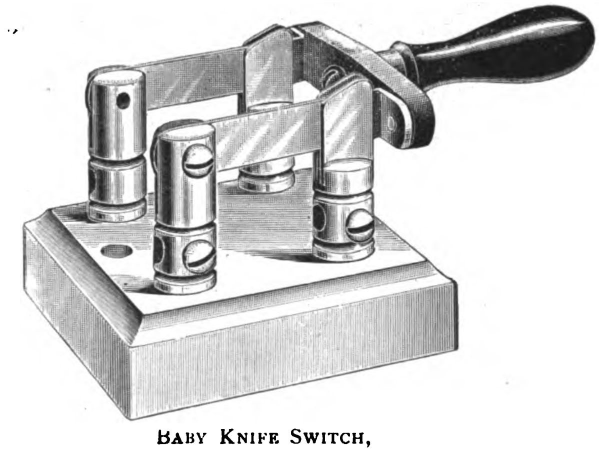
"SMALL, but select," is a phrase that would apply appropriately to the exhibit of the National Carbon Co., of Cleveland, whose display in Section G, Space 156, is here shown. The uninitiated often express surprise on finding that electrical carbons are in such variety and profusion, and here they see that even in the single item of arc light points the opportunities for diversity are numerous. Of arc carbons there

THE NATIONAL CARBON CO.'S EXHIBIT.

is an excellent display. It is supplemented by a wide range of battery carbons and accessories, an important and interesting category. Perhaps the most striking group is that of carbon brushes for dynamos and motors. The conquest of the carbon brush is here exemplified and demonstrated in a very forcible manner. The exhibit is neatly draped and rounded out with photographs of the great factory at Cleveland, O. Mr. B. F. Miles was present to see the exhibit put in good shape at the start.

THE H. P. BALL MANUFACTURING CO. AND ITS EXHIBIT.

A NEW corporation under the above title has just been formed for the manufacture of electrical apparatus and supplies, with headquarters at 101 Beekman street, New York City, the factory being located in Brooklyn. The company are prepared to furnish estimates on switchboards and special apparatus, and call particular attention to their baby knife



BABY KNIFE SWITCH,

switches, herewith illustrated. These are larger than the other makes on the market, having a capacity of 35 amperes, although they are called 25 ampere babies. The switch is mounted on a large porcelain base and has highly polished parts which are lacquered thoroughly to retain their brilliancy of machinery polish. The switch is well made by special machinery for this purpose, and the company is prepared to furnish the trade with a first-class article at a very low price. It will also manufacture and sell switchboards,

switches, distributing boards and electrical appliances of all kinds.

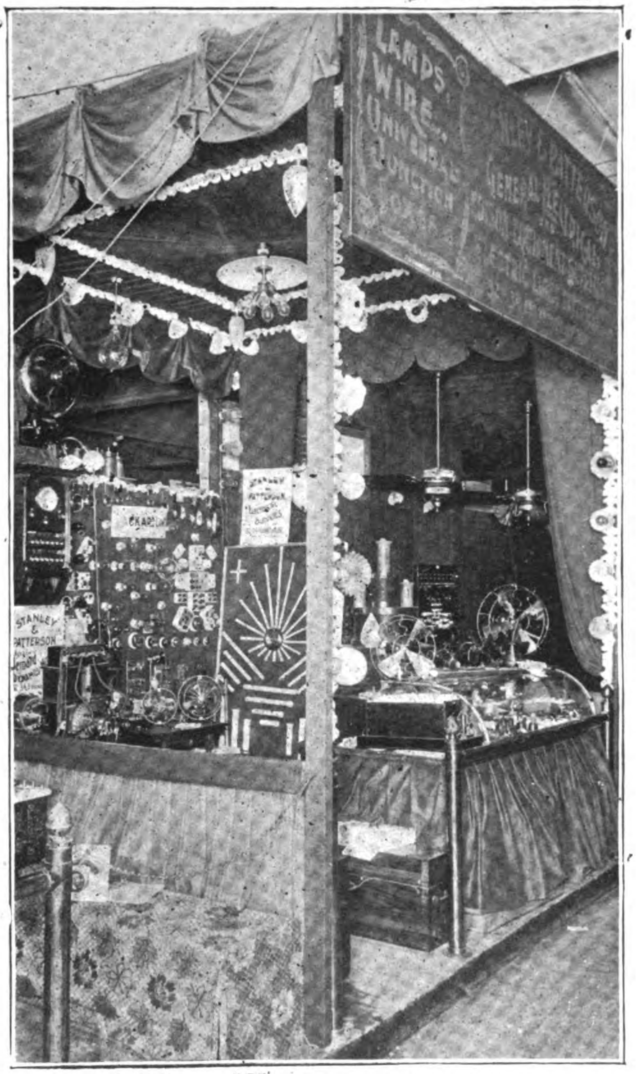
Mr. H. P. Ball, the president of the company, has been in the electrical field for ten years, most of which time has been spent with the General Electric Company, both in New York and Schenectady. While in this employ Mr. Ball designed the complete equipment of electric switchboards used in the United States Navy, and afterwards, as superintendent of the Carpenter Enamel Rheostat Company for two years, he designed a number of new appliances and improved types of rheostats.

The company's factory is thoroughly equipped with the best machinery and well adapted to turning out first-class work. They will be glad to correspond with all possible customers and agents.

At the exposition the company show a handsome switchboard of their "Baby" switches, with a capacity of 35 amperes, which is the biggest "Baby" on the market. In addition to these the company make switches and switchboards of any capacity. Their work, as illustrated at the show, is much admired.

THE STANLEY & PATTERSON EXHIBIT.

STANLEY & PATTERSON have one of the most attractive booths in the exhibition, consisting of all kinds of general electrical supplies. Among the specialties are Packard lamps, the booth being lighted by fifty 16 candle-power lamps of different colors and one 500 candle-power mogul lamp. A part of



THE EXHIBIT OF STANLEY & PATTERSON.

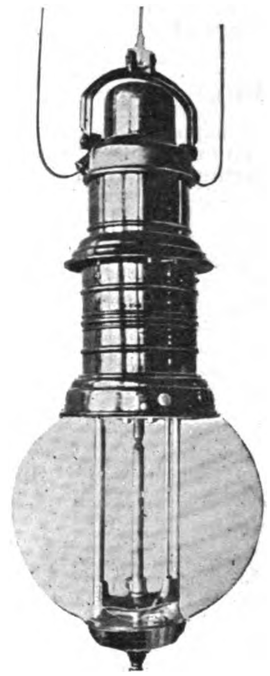
these lamps are run by a motor generator manufactured by E. G. Bernard Company, of Troy, N. Y.

In one side of the booth is placed a sample board, nicely arranged, of Brunt & Thompson's porcelain tubes. Near the center of the booth is a pyramid of Paranite wire, which is made by the Indiana Rubber and Insulated Wire Company. Jonesboro', Ind.

The exhibit is in Section F, on the main floor, and is thus advantageously placed. It catches everybody's eye, and having attracted attention, holds it.

THE REACTANCE SYSTEM OF ARC LIGHTING.

ONE of the most interesting arc lighting improvements shown at the exposition is that known as the "reactance system," the invention of Mr. W. S. Horry, who is kept busy explaining it in the booth of the United Electric Improvement



THE HORRY REACTANCE LAMP.

Company. Mr. Horry brought out this system in 1894.

Lamps of the ordinary Helios type are used with the addition of a small coil of thick wire built in them. The lamps are in series and are fed from the primary current of an ordinary alternator. The system is automatic, the current on the line remaining constant even if the carbons are all burnt away. There are no transformers, fuses or shunt spools employed.

The complete system comprises one transformer, which is located at the station, and a small switchboard. With these the proper current can always be served into the line, so that forty or less 2,000 candle-power lamps can be run on one series line from a 1,000 volt alternator, or eighty lamps may be run in series from a 2,000 volt alternator.

The current required from the alternator varies with the number of lamps in series and on the line itself a constant current of fifteen amperes is used.

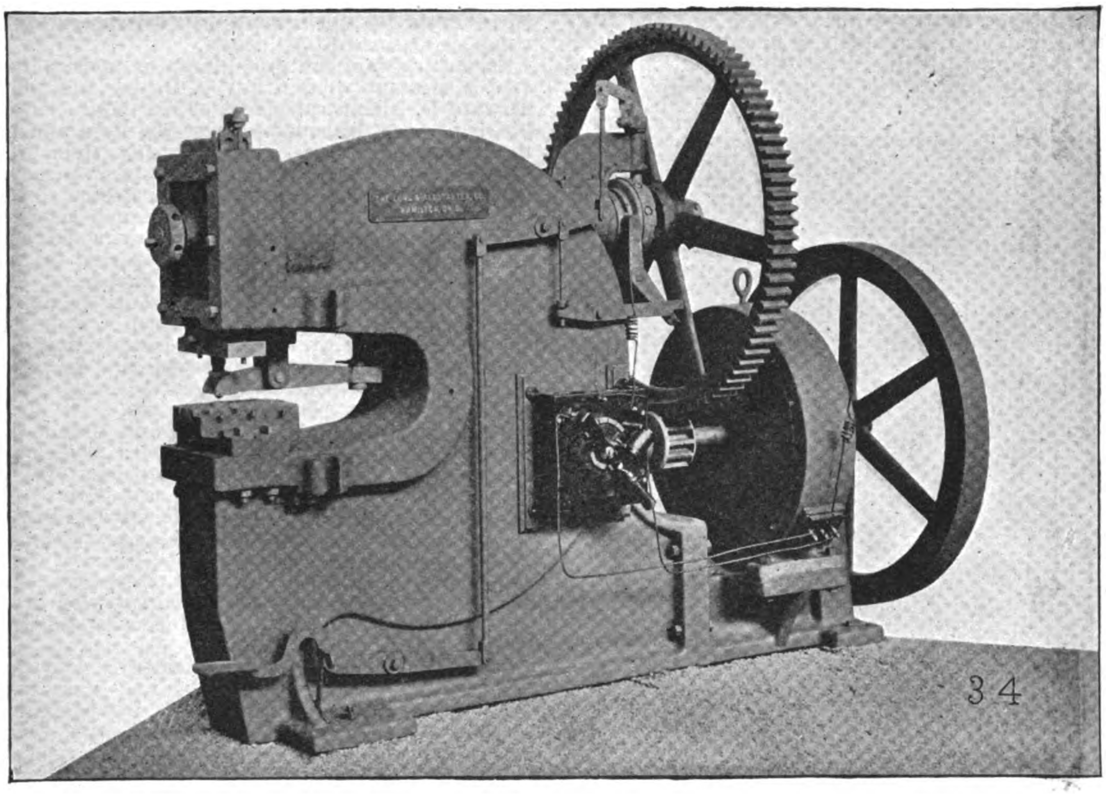
One of the strongest features of the system is the low cost of installation, and in this respect it is claimed to be far superior to the transformer system. Judging by the comments of electric light men who have seen the system and heard Mr. Horry's explanations of it, a rapidly increasing application of it may be looked for. It is already in operation on a dozen street lighting stations, and all the managers and engineers visiting the show insist with genuine anxiety on getting full details.

SPON & CHAMBERLAIN.—Glancing over this company's exhibit, the old saying is recalled, that we cannot have too much literature. Their exhibit is very complete, and Mr. Spon himself gave it his personal attention.

THE OKONITE CO.—Well located to the left of the main entrance are the cosy quarters of the Okonite Company, presided over by Captain W. L. Candee and Mr. George T. Manson. The booth is tastefully decorated in yellow, and is a reception room as well as a bureau of information. The most characteristic point about the exhibit is the total absence of all wire coils, a few samples of Okonite mounted on cards being all there is to remind the visitor of the company's mission in life. The company is evidently of the opinion that not to know Okonite is to confess oneself unknown. Gum-chewing young ladies gaze with envy upon a 700-pound ball or "biscuit" of Para rubber which forms the pièce de résistance of the exhibit, and two football teams are now being organized to play a game in which the great Okonite ball will be used.

A CARD MOTOR-TOOL UNIT.

We illustrate herewith one of the many applications of electric power to which the Card Motor and Dynamo Company have been paying special attention with much success. The tool shown is a Lang & Alstatter punch, and, as will be observed, the location of the motor is such as to interfere in nowise with the best and most economical operation of the tool. These direct-connected Card motors are a feature of the show.



Lang & Alstatter Punch Driven by Card Motor Direct Connected.

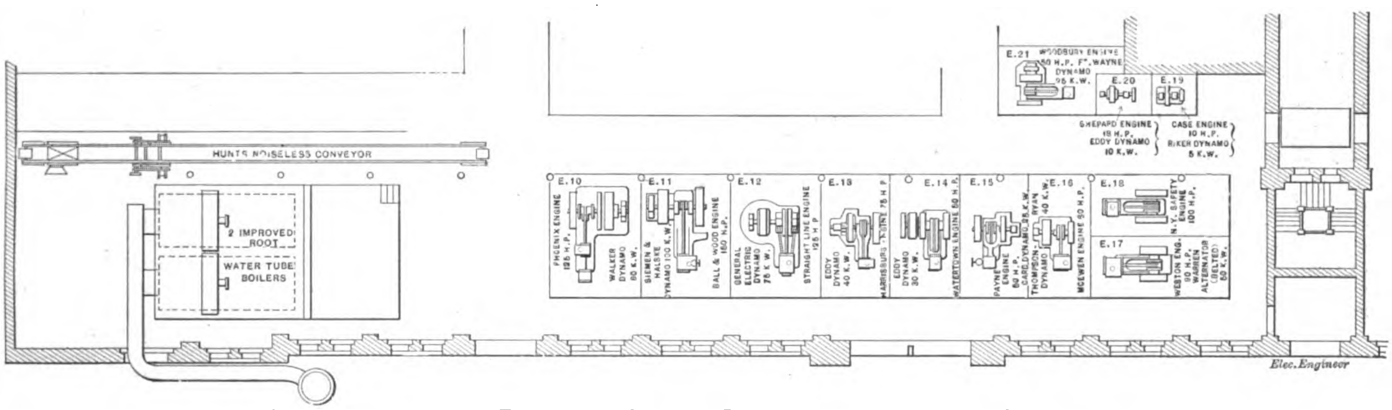
EXPOSITION POWER PLANT.

Probably the most instructive object lesson, to every steam user visiting the exposition, is the truly magnificent display of engines and dynamos in the generating department. True, the results are not as large and imposing as those shown at the Columbian Exposition, but for design and execution from both the electrical and steam engineering standpoints the present display may fairly be said to eclipse anything thus far brought to the notice of the public.

The accompanying diagram will give some idea of the extent and variety of the display. The most characteristic feature, of course, is the proponderating number of direct connected units, only two out of the twelve dynamos being driven by belts. The unit nearest the boilers is that of the Phœnix engine of 125 horse-power, which drives a Walker 50 kilowatt dynamo. This is the only compound engine shown at the exposition. Then follow in regular order the following: Siemens & Halske 100 kilowatt dynamo, with interior pole pieces, direct connected to a Ball & Wood 150 horse-power engine; General Electric multipolar 75 kilowatt dynamo direct connected to a Straight Line, 125 horse-power engine; Eddy 40 kilowatt dynamo direct connected to a Harrisburg "Ideal" 75 horse-power engine, which unit was illustrated in our last issue; Eddy 30 kilowatt dynamo direct connected to a Watertown 50 horse-power engine, Card 25 kilowatt dynamo direct connected to a Payne 50 horse-power engine, Thompson-Ryan 40 kilowatt dynamo direct connected to a McEwen 60 horse-power engine. The two dynamos at the end of the line are belt driven; one of these is the 50 kilowatt Warren alternator (the only alternating machine in the power plant), and is driven by a Weston 90 horse-power engine, and an 80 horse-power Crocker-Wheeler dynamo driven by a 100 horse-power New York Safety engine.

On the other side of the main aisle are two small direct driven units. That at the end consists of a Riker 5 kilowatt dynamo direct driven by a Case 10 horse-power engine, and in the adjoining space is an Eddy 10 kilowatt dynamo driven by a Shepherd vertical engine. Finally, there is a 25 kilowatt Fort Wayne dynamo direct driven by a Woodbury 50 horse-power engine.

The power plant is completed by a pair of 500 horse-power Root boilers, to which coal is supplied by a Hunt noiseless conveyor, which also disposes of the ash.



Arrangement of the Engine and Dynamo Plant at the Electrical Exposition.

HARRISON J. SMITH.

THE president of the National Electrical Exposition Company, Mr. H. J. Smith, has found his position one of so much importance in the eyes of the public of New York and of the electrical community that it is likely he would hardly have accepted his office had he known of the fierce light of journalism that would be brought to bear upon him and upon his conduct. He has, however, stood the ordeal with a due admixture of modesty and equanimity, and now it is in order to congratulate him upon the success of the great enterprise which has been uppermost in the thoughts of himself and associates for

HARRISON J. SMITH.

so many months past. Mr. Smith, as a typical central station man, was a fortunate selection for the post, while the curious compound of aggressiveness and conservatism that makes itself felt in all his actions and in every conversation, was just about the element needed to approve the good things and frown down on the undesirable.

Mr. Smith is the superintendent of the Edison Electric Illuminating Company, of New York, the largest of its kind in the world, and nothing more need be said to indicate the nature of his daily duties, and of the work required in their discharge. It has been good training for the control of an electrical exposition.

SUPT. MARCUS NATHAN.

Upon no man has the actual work of putting the National Electrical Exposition in good shape fallen more heavily, to be discharged more efficiently, than Mr. Marcus Nathan, the cheery and imperturbable superintendent. His familiarity with the vast building and with exposition methods in general have been invaluable, and while the exigencies of the present case have presented many problems, Mr. Nathan has mastered them all successfully. Only by dint of hard work could this have been done, and Mr. Nathan has literally camped on the spot, spending days together within the building. His courtesy and kindness to all, even to exasperated exhibitors with real or imagined grievances, have won him hosts of friends in the electrical field. His work has been genuinely well done.

MR. S. M. HAMILL, JR., was a visitor to the show last week on several nights, escorting well known members of New York society, who, under his expert guidance, saw the best of everything in the minimum of time.

MR. A. A. KNUDSON has lent valuable aid to the exposition in fixing up the electrical part of its inaugural exercises. He has also arranged other features, including a lamp baton for the band conductor.

MESSAGES AROUND THE WORLD FROM THE EXPOSITION.

ON May 16, at the National Electrical Exposition, a notable feat in land and submarine telegraphy was attempted and successfully carried out, to the great credit of all concerned. In addition to the sending of messages around the world, Mr. Chauncey M. Depew delivered a fine oration on "The Progress and Future of Electricity." There was an audience of some 10,000 people.

To demonstrate the promptness of modern telegraphic service, a message written by Dr. Depew and addressed to Mr. Edward D. Adams, president of the Cataract General Electric Company, was transmitted over the lines and connections of the Postal-Telegraph Cable Company from New York, via Chicago, Los Angeles, San Francisco, Vancouver, Winnipeg and Canso, to London and back, via Boston to New York.

Col. Albert B. Chandler, president and general manager of the Postal-Telegraph Cable Company acted as the sending operator in the north balcony, and started the message on its long journey at 8:34 o'clock. Mr. Thomas A. Edison, who in his younger days was also a telegraph operator, received the message in the south balcony when it came back, handing out a copy in his own beautiful handwriting, to Mr. Adams, at 8:38 o'clock, the time occupied in carrying the message over 15,000 miles of a part of the Postal Company's overland and cable system being exactly 4 minutes.

The circuit between New York and Buffalo was energized with electricity generated by Niagara Falls at the plant of the Cataract General Electric Company. Mr. Depew's message and Mr. Adams' reply were as follows:

Message of Chauncey M. Depew to Edward D. Adams:

"God created, nature treasures, science utilizes electric power for the grandeur of nations and the peace of the world."

Message of E. D. Adams to C. M. Depew:

"Mighty Niagara, nature's wonder, serving men through the electric circuit, proclaims to all peoples science triumphant and the benevolent Creator."

When the message reached London, a copy was handed to the Eastern Telegraph Company and was forwarded by it over various lines and cables via Lisbon, Gibraltar, Malta, Alexandria, Suez, Aden, Bombay, Madras, Singapore, Hong Kong, Shanghai and Nagasaki to Tokio, Japan, returning thence via London and reaching the Exposition Hall at 9:24. The time was in reality a little short of this, but watches vary.

The Western Union Company and connections also transmitted a copy of the message from New York through Mexico, down the west coast and up the east coast of South America, thence to Spain and back to New York, the time occupied being 21 minutes. The arrangements for Mr. Depew's oration and the demonstrations of what is possible in long distance electrical transmission were largely due to the energy and care of Mr. F. W. Hawley, vice-president and general manager of the Cataract General Electric Company.

These demonstrations of the annihilation of time and space by means of modern telegraph facilities are the most extensive that have ever been undertaken. The invention of instruments and the construction of the vast system of telegraph lines and cables which make these remarkable feats possible have all been the work of scarcely more than fifty years, and a large portion of it of the last dozen years.

The very men who handled the messages in the hall are older than the science of which they are the masters, and there were many present who remembered the occasion of the sending of Morse's world-famous first message: "What hath God wrought?"

The Postal Company's instruments used were of their latest pattern, with aluminum levers. They are handsomely mounted on an ebony base, and will be presented to the Smithsonian Institute in Washington, together with attested records as to the time occupied in transmitting the massage and copies of every newspaper in the world in which the occasion may be noticed. These will be carefully preserved by the Smithsonian Institute as evidence to future generations of the advanced state of electrical science in this year of 1896.

The Western Union circuits were in the care of Vice-President Horne, General Manager C. A. Tinker, and Mr. G. W. Dickson as operator. The company occupied the center of the main balcony, and their apparatus was put within the frame of Moore tubes in which Governor Morton stood to open the exposition. By courtesy of General E. S. Greeley, the famous golden key was used for their work, and it attracted great attention.

The return of the messages after their flight through space was signalized by guns in circuit with the instruments. This part of the programme was carefully looked after by Mr. A. A. Knudson, and was a great success, the sharp boom of the gun giving just the needed emphasis to the course of events.

Over each gallery balcony was hung a huge glass arrow

built up of Moore's vacuum tubes. In the dispatching gallery, the arrow was headed to the air, away from President Chandler's key table. In the receiving gallery, the other arrow was headed downward towards Mr. Edison's table. As the messages left and returned, these huge glittering arrows were filled with strong phosphorescent light, whose flashes, as the circuit was made and broken now and again, served to give the vast crowds below and around a vivid and beautiful idea of electricity's actual passage around the circuit of the world from the balconies so near together.

EXHIBIT NOTES.

THE CRANE COMPANY display a full line of extra heavy valves and fittings up to and including 18-inch. They also exhibit a very large flange coupling, and other high pressure steam specialties, the good points of which are carefully explained by Mr. Fred. Mitchell.

THE NEW YORK LEATHER BELTING COMPANY have a tastefully decorated booth in which are displayed a 72-inch three-ply belt manufactured for the Louisiana Electric Light Company and a 42-inch wide two-ply belt. The decorations on their booth consist of columns of leather belting tied together. The exhibit is in charge of Mr. Robert Hilleck.

THE NEW YORK SAFETY STEAM AND POWER COMPANY exhibit in the basement a 14 by 16-inch horizontal engine belted to a 55 kilowatt Crocker-Wheeler generator, which supplies current for much of the lighting of the various exhibits of the exposition. The exhibit is complete in every detail and the successful working of this engine from the start deserves credit.

THE FERRACUTE MACHINE COMPANY, of Bridgeton, N. J., have a small space in which they have set up four punch presses, operated by electric motors, which are kept busy stamping out pretty souvenirs of aluminum. This company make presses for stamping armature discs, and Mr. Smith, of the company, appears to be the busiest man at the exposition, explaining to many the good points of his machines.

THE U. S. MINERAL WOOL COMPANY, of New York, attract a large number of visitors to their exhibit, which they find very interesting. It shows the process of turning hard slag into soft mineral wool suitable for the purpose of covering steam pipes so as to prevent radiation of heat. They also exhibit all forms and sizes of copper gaskets, pipe coverings and a variety of devices useful to the steam engineer.

THE ASHCROFT MANUFACTURING COMPANY'S display comprises a full line of pressure, vacuum and recording gauges. The Consolidated Safety Valve Company's exhibit in the same booth consists of a complete line of safety valves. Hayden & Derby have their exhibit with the above two companies, which consists of the Metropolitan double tube injector. Mr. J. Derby and Mr. F. T. Tapley represent the three above companies.

THE CLONBROCK STEAM BOILER COMPANY, makers of the Morrin "Climax" and the Morrin "Compound" boiler, display a small 10 horse-power boiler which they exhibited at the World's Fair, and several photographs showing a few of their various installations; they also display a photograph of the 20,000 horse-power "Climax" boilers to be installed in the new plants of the United Electric Light and Power Company, of New York City.

DALE, FARRELL & COMPANY, owing to the great call for bicycles, have gone into the bicycle business, and exhibit a bicycle, the frame of which is made entirely of wood. They also show a novel bicycle lamp which attracts a great deal of attention from visitors, especially those that use the wheel. They have perfected a new primary battery from which they expect great results, and show samples of it in their exhibit, which is in charge of Mr. Geo. A. Lietz.

THE PHŒNIX IRON WORKS, of Meadville, Pa., builders of the Dick & Church engine, show a compound horizontal engine which is one of the finest exhibits of its kind. It consists of a 50 horse-power engine direct connected to a Walker generator, the construction of the sub-base and method of supporting the cylinders being unique. Another peculiarity of the engine is that a heavy wheel is carried next to the generator, whereas the ordinary construction is to have no wheel on the generator side of the engine. Mr. C. A. White represents the company at the exposition.

MR. ROBERT A. KEASBEY, of New York, agent for Magnesia sectional covering, manufactured by the Keasbey & Mattison Company, of Ambler, Pa., have one of the finest exhibits in the line of pipe covering in the building. It consists of sectional samples of the different styles and shapes of coverings for steam pipes. This company have the distinction of supplying all the pipe covering of the exhibition, and also supplying nearly every ship of the U. S. Navy. Mr. C. H. Lietze, representing Robt. A. Keasbey, distributes a very pretty souvenir in the form of a calendar.

A VERY INTERESTING wall exhibit is that of De Veau & Company, New York. Many specialties are here exhibited, such as telephone exchange switchboards, which are connected at various points throughout the building; also wall sets of every description, for private use and exchange work; long distance apparatus, magneto bells, complete telephones, and their new carbon ball transmitter, which is shown in parts so that its construction may be inspected. Their steel "watch case" receiver only weighs 6 ounces. Mr. A. De Veau superintends this exhibit in an able manner.

THE JEWELL BELTING COMPANY, of Hartford, Conn., show a large assortment of belts, among which are a three-ply 69-inch dynamo belt sold to the Norwich Electric Light Company; a four-ply 79-inch belt, one inch thick, sold to the Washburn & Moen Manufacturing Company, of Worcester, the largest belt ever manufactured; and a 48-inch dynamo belt for the Passaic Electric Light Company. Mr. Chas. E. Ainsworth represents the Jewell Belting Company during the exposition, and Mr. Chas. E. Newton and Mr. C. L. Tolles were much in evidence during convention week.

THE GOLD STREET CAR HEATING COMPANY have arranged a very attractive working exhibit. They claim an almost complete conversion of electrical energy into heat, a possible graduation of heat, called the first, second and third degree, good workmanship and material, the facilities for making the heaters to suit any circuit, car or dwelling, and a handsome external appearance. On a recent evening, Mr. George J. Gould spent some time at this display, examining the various heaters, and expressed himself as very much pleased with their working. The display is presided over by Mr. John E. Ward and Miss Harriet Becker, who impart much valuable information and distribute to those interested, circulars and a report of a series of tests made on the heaters.

WHERE IS THE FIRE? is the question asked by many anxious visitors to the exposition. They hurry to the spot where the gong sounds to find themselves at the exhibit of the Gamewell Fire Alarm and Police Telegraph Company, who are showing in a most conspicuous and advantageous manner the working of their fire alarms and police signal systems. On each corner of the space marked 73—74 stands a lamp post, one carrying a fire box, the other a police call box, such as the company has installed in many of the largest cities. These boxes are connected to a central station and are in actual operation. They also show a fire alarm whistling machine, which, as the name indicates, whistles the alarm, instead of striking a gong. Numerous other devices complete this exhibit which demonstrates admirably the recent advancement which has been made in the application of electricity to the protection of human life and property. Messrs. A. L. Tinker and Chas. F. Waulen preside over this display.

J. C. VETTER & COMPANY, of New York and Philadelphia, who occupy the large corner space marked 80 to 81, Section J, have on exhibition a large variety of their electro-medical apparatus. A special tap is employed to obtain 110 volts, which device permits the lamp to remain burning while at another point of the socket the current may be tapped for other purposes. This is a new appliance, ingenious and useful, as it does not compel one to sacrifice light when desirous of using the current for other purposes. A small switchboard for galvanic and faradic currents, with Vetter carbon controller, and a very fine cabinet (similar to the one used at St. Luke's Hospital) is shown, which combines cautery devices and a diagnostic light. The Vetter dry battery which won a World's Fair prize is also shown. The exhibit also includes batteries, and many useful devices for medical and dental purposes. The exhibit is in charge of Mr. D. B. W. Bentley, who in a most able manner explains the workings of the various appliances.

THE HERZOG TELESEME SYSTEM.—Mr. F. B. Herzog is daily receiving at his booth the warm thanks of thousands of weary travelers who have used the teleseme to summon up cooling drinks and other necessaries in hotels during their travels. Though small, the Herzog teleseme exhibit is one of the most interesting in the whole exposition. It shows how intelligent thought has wrought undreamed of improvements in house and hotel communications. Among the variety of devices including the now well known teleseme is the Herzog hotel annunciator. One is fairly taken aback to see a 600 hotel annunciator board occupying no greater space than 14 by 14 inches. This is accomplished by using platinum buttons instead of the time honored arrow or electro-magnetic "drop." These buttons are immersed in a clear chemical solution and when the hotel guest calls, the little platinum button becomes discolored by the decomposition of the solution on its surface. When the hotel clerk has noted the call, he presses a rubber bulb, which injects air into the solution and washes the deposit off the platinum button, which reappears as bright as a new dollar. The Herzog police signal system is also shown in working order. Mr. Herzog and his bright young assistants keep the crowds well informed on the teleseme system.

THE D. VAN NOSTRAND COMPANY exhibit a full line of electrical literature and other technical works. Mr. C. L. Speirs is in charge.

THE PECKHAM MOTOR TRUCK AND WHEEL COMPANY exhibit one of their cantilever street car trucks, which have gone into extensive use all over the country.

A GREAT many favorable comments have been passed upon the wall display of Messrs. Geo. P. Hall & Son, New York, who show a beautiful collection of photographs of every description, exhibiting wonderful detail and beauty of tone.

MR. A. O. SCHOONMAKER, of New York, has a fine exhibit of mica sheets and stamped mica in all the various shapes required. The most important feature in Mr. Schoonmaker's exhibit are mica washers, shown in all sizes, and of which the firm make a specialty.

ONE OF THE most attractive exhibits at the exposition is that of the Birdsall Electric Manufacturing Company, of New York, manufacturers of electrical novelties, surgical and dental apparatus, electric illuminated clocks, musical jardinières, etc., and many very interesting and profitable advertising specialties. Mr. Birdsall himself welcomes the many visitors to his exhibit.

THE STIRLING COMPANY.—Among the noteworthy exhibits is that of the Stirling safety water tube boiler of 100 horse-power erected ready for the brickwork, so that the whole internal construction is visible. The simplicity of design of this boiler attracts much attention, as there are very few working parts, and very little machine work necessary in its construction, the tubes being all screwed directly into the drums.

HUEBEL & MANGER, of Brooklyn, N. Y., display a full line of electric bells, push buttons, etc., including their well-known style F bell, in sizes from three to fifteen inches, also a large variety of wood and iron box bells of different styles and sizes. Their representative, W. W. McChesney, Jr., is in attendance at the exhibit, and Mr. Huebel and Mr. Manger are on hand during the evening shaking hands with their many friends.

THE R. D. NUTTALL COMPANY, of Allegheny, Pa., exhibit gears and pinions for all systems, motor bearings, trolleys and trolley parts. They have the largest gear cutting establishment in the United States and are prepared to make gears and pinions for any desired system. Many radical improvements have been made by them in trolley devices and many advantages are claimed for them. Mr. T. J. Lord has charge of this railway supply exhibit.

THAT THE QUALITY, and not the size of an exhibit, determines its value to the profession is well exemplified by the display made by the Ball-Bearing Company, of Boston, Mass. We find here an upright carriage wheel on a stand, mounted upon ball-bearing axles, which with an ordinary impulse will run for 12 minutes before coming to rest. Other running machine parts, such as cable pulley, are shown, demonstrating the value of ball-bearings as friction reducers.

WAGNER ELECTRIC MANUFACTURING COMPANY.—The most complete exhibit of transformers is that made by the Wagner Electric Manufacturing Company, of St. Louis, in which they show all sizes of transformers and auxiliary apparatus. They gave away a very pretty inkstand in the form of a transformer, it being about 2 inches high, gold plated, illustrated in last week's issue. Mr. E. H. Abadie demonstrates how the transformers are used for commercial work.

THE VACUUM OIL COMPANY, of Rochester, N. Y., have a business-like exhibit in the engine and generator department over which Mr. E. A. Record, general sales agent for the electrical department, presides with all his usual courtesy. This company has been particularly successful in the manufacture of lubricating oils for engine and dynamo purposes, and those in charge of the generating plants in the exposition appreciate the quality of the oil which they procure from Mr. Record, and evidently know a good thing when they see it. Cans of oil are on hand at all times, and all comers are cheerfully supplied.

THE LAKON COMPANY, of Elkhart, Ind., exhibit ten transformers, ranging in sizes from 250 to 10,000 watts. They claim for these transformers good regulation and minimum watts lost in iron, well set forth in a descriptive circular distributed at the booth. They also exhibit an open type transformer of 5,000 watts capacity and 1, 2, 3, and 5 light economy coils. The E. B. Latham & Company have in operation in this space at present one of the Tuerk alternating current ceiling fans, which is very efficient and needs oiling but once a year. Mr. E. B. Latham, Eastern agent for these companies, is in charge of this very useful display.

AS IF GUARDING the Loan and Historical Exhibit a huge mast-arm with lamp attached extends from the very interesting corner display of the Peck Electric Company, T. H. Brady, and the American Carbon Company; in the space marked 82, Section J, we find here carbons of every description, mast-arms, cut-out boxes, motor brushes, battery carbons, carbon cylinders, rods, pole irons, iron brackets, sleet proof pulleys, storm-protectors and arc lamps; a very handsome chandelier, two Helios arc lamps, and a model of an electric fire engine which attracts a great deal of attention. In a most happy manner Mr. E. F. Peck imparts information on the great variety of apparatus made by the above companies.

OPPOSITE the Loan and Historical Exhibit is a space marked 46, Section C, Main Floor, which could not have been utilized for a better purpose than to exhibit therein the great variety of devices manufactured by the General Incandescent Arc Light Company. They exhibit in this space arc lamps for direct constant potential circuits, Bergmann standard rack rod lamps, Bijou arc lamps, long life inclosed arc lamps, burning 100 to 150 hours, arc lamps for constant potential alternating circuits, focusing alternating arc lamps, economy coils, Bergmann switches, and a great variety of Sun-Schmelzer-Nürnberg carbons for direct and alternating currents and searchlights. Mr. R. B. Corey, the general sales agent, and Mr. L. E. Frorup preside over this exhibit.

THE AMERICAN HEATING CORPORATION, of Boston, exhibit in space 60, Section D, in conjunction with the New York Edison Illuminating Company, a great variety of cooking and heating appliances, such as street car heaters of various forms, electric vulcanizers, gluepots, boilers, portable stoves, coffee urns, plate warmers, coffee pots, tea kettles, sad irons, curling irons, heaters, ovens, chafing dishes, etc. A well illustrated catalogue is distributed, and judging by the favorable comments passed by the ladies who gather around the display in great numbers, electric cooking and heating apparatus will rapidly win popular favor as soon as the electric current becomes a general household commodity. Mr. L. L. Parsons has charge of this useful and very interesting exhibit.

THE ELECTRIC ARC LAMP COMPANY'S space is not a large one, but what it lacks in size the exhibit makes up in interest and value to the visitor. The company show various styles of their Pioneer inclosed arc lamps, and no one than the inventor himself, Mr. L. B. Marks, knows better how to point out the advantages of the Pioneer lamp. Even without the exhibit the Pioneer lamp would make a good record for itself, since a large part of the general lighting of the exposition, and quite a number of the booths, are lit by Pioneer lamps. Comments of surprise and commendation are heard on every hand, as to the beautiful quality and steadiness of the light. The absence of shadows from the globes also is the subject of general and favorable comment.

THE STANDARD PAINT COMPANY.—"Come in and have a chair, or perhaps a cigar or a boutonnière," is the happy and welcome salutation one receives on nearing the exhibit of the Standard Paint Company, who occupy spaces 38—40, Section C, Main Floor. The hospitality of the exhibitors is only equaled by the very interesting exhibit they have to present to the public. In tasteful array, in glass cases and built up in pyramidal style the well-known and indispensable "P. & B." preservative paints and insulating compounds are arranged. The company also show their P. & B. armature and field coil varnishes, insulating tape, paper, and the P. & B. ruberoid roofing. Included in the exhibit is an extended assortment of the "Ship" solid and cored carbons, manufactured by Messrs. Schiff, Jordan & Company, of Vienna, for whom the P. & B. Company are agents. Mr. F. S. De Ronde, the general sales agent of the company, is in charge of the exhibit, assisted by the genial Mr. R. L. Shainwald and Messrs. J. N. Richards and Vandewater.

THE ABENDROTH & ROOT MANUFACTURING COMPANY, of New York, have undoubtedly carried off the palm as regards boiler exhibits, having secured the privilege of the only working boiler at the exposition. The exhibit consists of a battery of two improved Root water tube-boilers, of 500 h. p., which furnishes steam to all the engine and dynamo exhibitors. The boilers are worked above their rated capacity during the entire evening, 600 h. p. being required. The unique feature about this exhibit is that it is in charge of a woman, Mrs. Helene Walten, who performs the function of lady-stoker, with great success. Mr. Albert A. Cary, superintendent of the company, is to be congratulated upon his happy idea, which is intended to emphasize the fact, that a boiler room equipped with Root boilers is not only easy of manipulation, but can be kept tidy and clean, and free from all the usual dirt and ashes, so that even a woman can take charge. The boilers are fitted with Wilkinson automatic stokers, manufactured by the Wilkinson Manufacturing Company, of Bridgeport, Pa., and are fed by a Worthington electric pump. A Hunt noiseless conveyor is also in operation, and shows how easily and conveniently the fuel can be brought from any reasonable distance to the boiler room, and the ashes conveyed out of the room to any suitable dumping place. Mrs. Walten is ably seconded in her work by Messrs. John Kallery and James Avery.

THE HEINE SAFETY BOILER COMPANY show a very fine model of a 250 horse-power boiler, illustrating the internal and external parts of the boiler very clearly. Mr. H. L. Van Zile and Mr. R. T. Walker represent the company.

NO ONE could miss the exhibit of Mr. C. H. McIntyre, for a beautiful illuminated sign "McIntyre Connectors" blazens forth from the gallery at the East end of the main hall. Various types of McIntyre connectors are shown in this exhibit, which is situated in the gallery.

THE AMERICAN CIRCULAR LOOM COMPANY, of Boston, have a small exhibit, consisting of a few coils of their well-known flexible conduit for interior wiring. The exhibit speaks for itself, though Mr. Chas. D. Doubleday is in frequent attendance to extol the merits of this type of conduit.

THE STANDARD UNDERGROUND CABLE COMPANY'S exhibit includes a general display of the products of this company, consisting of samples of their standard wires and cables, not only for underground distribution, but for general electrical purposes. The exhibit is neatly arranged on racks and tables.

THE McEWEN MANUFACTURING COMPANY have a very live exhibit in the generating department, consisting of one of their 60 horse-power high speed engines direct connected to the Thompson-Ryan 40 kilowatt dynamo. The unit operates with great smoothness and the construction of both engine and dynamo elicits much favorable comment.

THE WALKER COMPANY'S exhibit consists of an 80 kilowatt dynamo direct driven by a Phœnix 125 horse-power engine, which forms a prominent feature in the generating department; besides this machine the company also show a variety of railway equipment, consisting of motors, controllers and their standard railway switchboard panels.

NILES TOOL WORKS.—The only exhibit of heavy machine tools run by electric motors is made by the Niles Tool Works. Their exhibit includes a 37-inch boring mill run by a 3 horse-power Card motor, horizontal boring machine run by a 2½ horse-power motor, a radial drilling machine run by a 2 horse-power motor. From Mr. E. D. Becker's demonstration the visitor will readily see what a large field is open to the application of electric motors for driving machine tools.

JOHN A. ROEBLING'S SONS' CO.'S booth is decked with heavy satin curtains, and in this pleasant abode every friend receives a cordial welcome. There are on exhibition samples of the celebrated bi-metallic wire. This special department is presided over by Mr. Willard M. Miner, representing the Bi-Metallic Electric Transmission Company. All types of wires are shown in the exhibit supervised by Mr. M. R. Cockey, of the Roebling Company's New York office, and Mr. V. L. Doyle, of Trenton, N. J.

THE EXHIBIT of the Warren Electrical Co. consists of a 60 kilowatt Warren alternator, driven by a Weston engine. The alternator is so built as to generate single or two-phase currents, and allows of the taking off of 104 and 1,000 volts at the same time, completing two separate circuits from the terminals of the machine. They also have on exhibition a 45 kilowatt alternator supplying current for the whole building, the machine being of the induction type.

A. K. WARREN & COMPANY have a very interesting exhibit, devoted particularly to illustrating the repair and care of dynamos. The exhibit is a live one, as armatures are actually repaired by workmen, thus giving an apt illustration of the manner in which this work is carried out. The exhibit also includes dynamo motor brushes and brush holders, turning tools for cutting down commutators whilst in the field, and other repairing devices. Messrs. Stanmore and Warren are in attendance and are kept busy answering questions.

THE WESTON ELECTRICAL INSTRUMENT CO. show their well known types of measuring instruments. Their mascot is an 80,000 ampere station meter, showing that the company is equal to any emergency. They also exhibit a new small round pattern ammeter and voltmeter, the Van Vleck edgewise system of station indicating instruments, and a full line of laboratory standard instruments. They also exhibit a line of special alloy shunts, having negligible temperature co-efficients. Mr. A. J. Pionnie has charge of the exhibit.

THE SIMPLEX INTERIOR TELEPHONE CO., of Cincinnati, O., show their new hotel telephone and private line system, exhibited in conjunction with the Partrick & Carter annunciator. The system elicits much favorable comment. It may be used with any style of annunciator and can be attached to existing wires, obviating the necessityof rewiring. The Simplex 'phones are scattered throughout the exposition and Mr. W. L. Bradshaw, who represents the company, is kept busy answering calls and explaining the beautiful simplicity and non-infringing character of the apparatus.

THE BISHOP GUTTA-PERCHA CO. have an interesting display which has many educational features. Rubber and gutta-percha are shown in their crude state and during the various stages of manufacture. They show a full assortment of Balata wire, lamp cords, submarine and underground cables, the celebrated Marks compound and a piece of an old-time gutta-percha pipe laid in 1848 to supply Blackwell's Island with water. There is also shown a reel of copper-armored cable for lighting the main channel buoys off Sandy Hook. This interesting exhibit is in charge of Mr. Harry D. Reed.

THE PARTRIDGE CARBON COMPANY, located in the annex, exhibit a large assortment of carbon brushes for dynamos and motors, and other carbon specialties, manufactured by the firm. Though small, the exhibit is well arranged and attracts much attention.

THE RIKER ELECTRIC MOTOR COMPANY show one of their specialties—a model steam yacht lighting plant, consisting of a 5 kilowatt Riker dynamo direct driven by a Case engine. The plant is exceedingly compact and operates almost noiselessly. The exhibit also includes a number of Riker motors for power purposes, and also the Riker fan motors.

THE ANCHOR ELECTRIC COMPANY have a very handsome exhibit, in which they show samples of almost everything used in electrical supply departments. The exhibit is in charge of Mr. Field, their New York representative, though Messrs. Hawks, Reynolds and Marshall, of Boston, are frequently to be seen and appear to have a host of electrical men interested in their goods. They have a handsome electric sign in the exhibit, consisting of incandescent lamps with letters on the face, reading the name of the company. Their samples of cut-outs, rosettes, switches and general household goods are arranged with great taste.

THE WESTON ELECTRICAL INSTRUMENT COMPANY have a very comprehensive exhibit of their products, consisting of portable voltmeters, ammeters and wattmeters, covering a wide range of work; and also a complete set of their laboratory standard instruments. The front of the booth facing the historical exhibit is covered by a switchboard, upon which the Weston instruments of the dial pattern are mounted, illustrating their use in central stations and private plants. The Jumbo of the exhibit is a dial instrument indicating up to 60,000 amperes, thus showing that the company is prepared to build anything which may be called for in practical work.

THE CUTTER ELECTRIC AND MANUFACTURING COMPANY, of Philadelphia, have a very attractive exhibit, in which they show working samples of their automatic cut-outs, designed specially to take the place of fuse wire, and which they claim are much more reliable. These cut-outs are now becoming acknowledged as a most valuable device for all switchboard work, and have received the highest indorsements from electricians and electrical engineers from all over the country. They also distribute a large number of their most recent catalogue, which every station manager should procure. Messrs. Henry B. Cutter, A. E. Newton, W. E. Harrington, and Wm. Nicholson, are in constant attendance and carefully explain the merits of their goods.

GEORGE A. MACBETH & CO., the well-known glass manufacturers of Pittsburg, Pa., have a number of patterns of their "Holophanes" on exhibition, which bid fair to add fresh laurels to their wide reputation. The "Holophane" is a glass globe, the surface of which is pressed into prisms and possesses the merit of equally distributing light with but little loss of brilliancy. The efficiency of this new globe is obviously of the highest, both in incandescent and arc lighting. This firm expect to have the " Holophanes " on the market in a few days, and judging from the numerous inquiries of electric light contractors and others, the success of the globes is assured beyond a doubt. This new article is a French invention, Messrs. Macbeth & Co., holding the United States patents. They will take pleasure in sending a descriptive pamphlet of this new system of illumination to any address on application.

THE SAFETY INSULATED WIRE AND CABLE CO.'S exhibit occupies an area of 400 square feet, and forms one of the most novel and attractive features of the exposition. The booth presents the appearance of an art gallery, its walls being covered with fifteen heavy oak frames, each inclosing, to all intents and purposes, an apparently blank canvas; but presently there appear beautiful electric pictures and signs showing and telling of the company's achievements in different parts of the country. One frame contains a Western Union telegram blank, which spells out, one word at a time, an invitation to the visitors to visit the company's factory. The central sign makes the firm's name appear and disappear, and each word also changes its color. Other signs give information about cables, and smaller frames with letters of commendation are placed on easels. In connection with this unique display the railing of the space consists of sample boards on which samples of submarine, underground and aerial cables of every description are most tastefully let into the wood like mosaics. Wires for interior and out-door work, reels of various cables and wires complete the outfit of this most attractive exhibit, which is in charge of Mr. F. T. Richards, the manager of the telephone department, and Mr. LeRoy Clark, the company's electrician.

THE BUYER'S REFERENCE CO. issued a special electrical edition of their "Buyer's Reference Book." Their booth was in charge of Messrs. N. W. Gage and A. R. Curtain.

THE IRON CLAD RHEOSTAT COMPANY engaged 100 square feet of space at the exposition, but were so pushed to fill orders that they could not spare the apparatus to make an exhibit.

MR. J. S. SPEER, secretary of the Partridge Carbon Company, of Sandusky, O., was an early arrival for the convention and exposition. He reports business large and increasing all the time in their excellent carbon specialties of all kinds.

THE EXHIBIT of the Thomson Meter Co. is quite small but complete. It embraces all sizes of meters from 1 to 3-inch, inclusive, with the new straight-reading dial; also, their new meters with the new Lambert gear. The exhibit is in charge of Mr. S. D. Higby.

COLUMBIA RUBBER CO. exhibit every style of rubber goods used in the electrical line from a washer to a telephone receiver. The latest article manufactured by them is a compound composed of asbestos and other insulating materials. Their booth is very prettily decorated.

THE BABCOCK & WILCOX CO. make a good display of their boilers and parts, including sections and wrought steel plates of high pressure, sectional water tube steam boilers, a complete line of high pressure steam pipe fittings; also a very fine model complete of their forged steel sectional steam boiler.

THE GOUBERT MANUFACTURING CO.—The Goubert Manufacturing Co.'s exhibit consists of models of the Goubert feed water heater and Stratton separator. This company has the proud distinction of having a Stratton separator on every engine in the exposition generating plant and the only feed water heater used there.

THE FOREST CITY ELECTRIC CO. exhibit their celebrated roll drop and drop forged commutator bars for generators and street railway motors. The bars are tastefully arranged on boards, and the advantages claimed are admirably set forth in specimens illustrating the process of manufacture Messrs. W. B. Cleveland, and J. C. Dolph, manager of the New York office, are in charge.

THE IDEAL ELECTRIC CORPORATION, of New York, show a full line of La Roche alternators, Ideal Fleming arc lamps and focusing lamps of which they make a specialty. One of their five kilowatt alternators may be seen in operation at the booth of E. B. Latham, furnishing current for the Tuerk alternating ceiling fans and Ideal Fleming arc lamps. Messrs. F. A. La Roche and George S. Loutey are in attendance.

METROPOLITAN TELEPHONE AND TELEGRAPH CO. —A very novel and enterprising exhibit is made by this company. It consists of a model hotel pay station with monitor switchboard, showing the public graphically the business-like manner in which a pay station is run. The public as well as the exhibitors are very generously allowed to telephone about town free of charge. Mr. Samuel B. Brewster has charge of the exhibit.

MR. E. G. BERNARD, of Troy, constituted himself a walking exhibit, as it were. Though he had nothing to show, Mr. Bernard transfixed his friends by presenting them each with a box of delicious, gold-tipped, Turkish cigarettes of Jumbo size, and his friends were legion when the fact became known. Incidentally Mr. Bernard also mentioned the high grade dynamos and motors with forged fields and other latest electrical and mechanical improvements which the E. G. Bernard Company manufacture.

THE BRADFORD BELTING CO,. of Cincinnati, display a complete line of their Monarch insulating paint, which is so widely used for insulating armatures, fields, etc. Mr. Elmer P. Morris, who is in charge, never tires of applying the torch to the Monarch-painted wood and iron, but always without any damaging effect. Mr. Hubbard, of Cincinnati, was also in attendance during the first week of the exposition, and made for himself hosts of friends in the East, and left behind him a very favorable impression of the specialties of this live Western house.

THE EMPIRE SELF-LIGHTING LAMP CO. have attracted to their tastefully decorated booth large crowds who appear much interested in their self-lighting oil lamp. These lamps to all appearances are like any ordinary lamp, but require no matches or flame to light them, having concealed in their base two cells of dry battery, which by rendering a small platinum point red hot, sets flame to the wick when desired. The young lady in charge is indefatigable in her attentions, and the fact of being able to light an oil lamp, by merely turning a little thumb screw commends itself to all visitors.

DIEHL MANUFACTURING CO.—A bewildering display of ceiling fan motors is made by the Diehl Manufacturing Company. Their exhibit also contains a very full line of fancy arc lamps, and to represent their motor department they had in operation a 5 horse-power Diehl motor running a 5 horse-power Diehl generator. The booth was decorated with great taste, and the lady visitors were specially interested in watching Messrs. Knight and Bennett, who were in constant attendance, deftly manipulating a sewing machine operated by a Diehl motor, which is readily controlled by the foot of the operator.

THE COLUMBIA INCANDESCENT LAMP CO.'S exhibit is designed to demonstrate the use of the incandescent lamp in commercial, house and sign work. The latter is represented by a sign composed of over 100 lamps of ¼ candle-power, making a very attractive appearance. Those who recall the lost cause will find a melancholy interest attaching to the group of Goebel lamps, which were used as evidence in the fight between the Edison and Columbia companies. Mr. Rhotehamel, who was in charge during the convention, also explained the details of filament making by samples of the material in the various stages of manufacture, and Mr. Garrison had a pleasant mood for all callers.

THE UNITED STATES PRISM GLASS GLOBE CO. have an attractive exhibit of glass globes with prisms on the inside, which have the effect of softening and diffusing the light. It is claimed that these prism globes not only distribute more effectively than plain globes, but actually increase the effective power from 10 to 73 per cent. over other globes, besides having the appearance and beauty of cut glass. They are made in all colors, and as they emit a softened light, are of much use in hospitals and other places where nervous diseases are treated. The exhibit is in charge of Mr. A. Pond, who takes great pleasure in explaining to visitors the peculiar merits of the prism globes.

THE BRYAN-MARSH CO.'S exhibit consists of a bewildering array of lamps of all descriptions, including a solid bank of 2,000 tubular lamps, covering 26 square feet. By means of a switchboard the lamps are made to spell out in letters various political axioms and to represent figures of varying outlines. It is needless to say that a crowd is always in front of the booth, to listen to Mr. Marsh's dissertation on the value of his lamps. Not a little attention is also attracted by the illuminated curves of efficiency comparing the Bryan-Marsh with Edison lamp. The test was made by Stone & Webster, of Boston. These curves gave rise to quite a little controversial breeze between the representatives of the two companies recently, but no blood was shed.

THE PERU ELECTRIC MANUFACTURING CO. received a strong testimonial letter on the quality of their carbon for electrical purposes—as noted elsewhere. This firm have had for the past few years a steady and increasing demand for goods, owing to their superiority. Their carbons, coarse grained, open and porous, are recommended especially for sal ammoniac batteries. The well-known Laclede, also Hercules battery, are of their make. The Peru Electric Manufacturing Company's largest output, however, is in porcelain sundries, of which they turn out a full line, as well as manufacture on order. "Peru" porcelain is guaranteed of highest quality, hard burned and thoroughly vitrified. A few of their specialties are rosettes, switches, main and branch cutouts, tubes, porcelain knobs, wall receptacles, etc. Natural gas is the fuel used throughout their extensive plant. The Peru Electrical Manufacturing Company have an excellent display of their wares at the Electrical Exposition, which is at present in charge of their enterprising and genial treasurer and manager, Mr. A. H. Bouslog.

THE FORT WAYNE ELECTRIC CORPORATION occupies a space covering an area of 200 square feet. In one corner is located a switchboard with switches to control the single-phase, self-starting synchronous motors, which are the feature of their exhibit, together with voltmeters and amperemeters, and a bank of incandescent lamps. These are fed by the direct current dynamo, which is used to load the 5 horse-power single-phase alternating current motor running on the low frequency circuit of 7,200 alternations generated in the building.

One of these motors, which was described by Mr. F. H. Leonard in the paper read before the convention, is adapted for use as a rotary transformer and driven as a shunt wound direct current motor, and transforms this 110 volt direct current fed in at the commutator brushes into an alternating current of 16,000 alternations for running a 10 horse-power and a 2¼ horse-power single phase motor. A sub-station transformer of 375 lights capacity and a standard transformer of 125 lights capacity are shown together with primary fuse boxes. In the generating department, in the basement, the company has a 25 kilowatt direct connected direct current incandescent dynamo driven by a Woodbury engine.

This very attractive and complete exhibit is in charge of Messrs. F. H. Leonard, J. O. Lott and T. H. Nathans.

ONE OF THE MAIN attractions at the exhibition is that made by the United States Patent Office. It consists of models of many devices which have made fortunes for their inventors.

THE CALCULAGRAPH CO. exhibit a very complete line of their instruments, namely, those adapted for calculating, recording in hours and minutes, or dollars and cents. They demonstrate in a practical manner how the machines are used.

KEUFFEL & ESSER CO.—The only exhibit of draughting and surveying instruments is made by the well-known house of Keuffel & Esser Co. The exhibit includes an assortment of the latest drawing and surveying instruments. A complete line of field engineers' outfits, calculating machines, and the latest type of planimeters used fro figuring horse-power from indicator cars. Mr. Schildecker is in charge of their exhibit.

BALL ELECTRIC LIGHT CO.—The display made by the Ball Company, while not extensive, is quite representative in character. It consists of a 100-light, 10 ampere machine; a 50-light, 6 ampere machine, of their well known "unipolar" type. Their booth is decorated plainly, but very neatly, and the familiar face of Mr. W. J.Morrison now greets all visitors, as he has recently made connections with this company as special representative. Messrs. Charles E. Ball, J. S. Bell and J. C. Williamson are also in attendance.

THE BERNSTEIN ELECTRIC CO. have a fine display of incandescent lamps set off to advantage by the pink and white decorations. The lamps are arranged in pretty designs, and are of all colors, shapes and sizes, for multiple and series circuits. A special socket is also shown, as well as a display board illustrating the use of all alternating current street systems for incandescent lamps placed in series between the primaries of the converter. The exhibit is presided over by Messrs. H. B. Cram, J. Bradley, and Cartwright.

THE CHAPIN-DOUGLAS ELECTRIC CO. have utilized their space to excellent advantage. They show a complete direct-current switchboard fitted up with Eyanson & Armpriester switches of special design. A railway switchboard shows the Eyanson quick break switch for high tension circuits. In a neat glass case are shown the following specialties: The C-D rosette, with adjustable contacts and interchangeable caps; Burnley's soldering paste, which is non-corrosive and always plastic, needing no heat to soften it; also, the C-D incandescent lamps, and the "Perfection" dynamo brush, made of gauze, giving ventilation and reducing sparking. The exhibit is in charge of Mr. Charles E. Chapin.

A VERY PRACTICAL and instructive working exhibit is that of Henry R. Worthington, and fills a space of 200 square feet. The special features of the display are the electrically driven pumps, horizontal, vertical, duplex and triplex. There is in operation a house tank pump of 250 gallons capacity per hour, belted to and on the same bedplate with a Crocker-Wheeler motor. These pumps have already been widely introduced for house tank and similar service, and special designs have been made to cover the requirements of hydraulic elevator service, mine service, water-works supply, irrigation purposes, fire protection, or, in short, any service where electric motive power can be used to advantage. They also exhibit some of their triplex steeple power pumps, which are made up to a capacity of 1,000 gallons.

A very interesting feature is their celebrated 1½-inch test meter with special fittings. A carefully constructed model of a compound high duty pumping engine also attracts a great deal of attention. Blueprints showing the layout of water works plants, mine pumping and elevator plants are kept on file, and a very attractive special edition of their catalogue is distributed to all interested in pumping machinery and modern applications of electric power. The exhibit is in charge of Messrs. F. W. Jones and T. B. Cummings.

THE HOLTZER-CABOT ELECTRIC CO. occupy a prominent space to the left of the main entrance, and theirs is one of the coolest corners in the whole exposition, thanks to a large number of their fans in operation. They have also placed a number of their fans in other exhibits, adding largely to the comfort of visitors. Their new ceiling fan attracts a great deal of attention, both on account of its small size and attractive finish. It weighs, complete, less than 30 pounds, is but 7 inches in diameter, and consumes only 60 watts. The exhibit shows the large line which the concern carries, including bells, annunciators, clocks, and burglar alarms. The exhibit is particularly interesting on account of the large variety of special applications of motors shown, including organ-pumping combinations, emery wheels, direct driven and alternating and direct current motor generators for all kinds of service. A large line of dynamos and motors is shown. These machines, taken out of stock, show great care in construction and attention to details. The exhibit is in charge of Mr. C. E. De Lue. The Electrical Engineer is indebted to this company for the handsome fan motor which serves to keep its little space cool and comfortable even on the hottest night.

PASS & SEYMOUR, of Syracuse, have a very attractive display on the main floor. The walls of the booth are covered with all shapes and 300 sizes of glazed and unglazed tubing, insulators, china cleats, cut-outs, and cut-out insulators, rosettes, ceiling buttons, tree insulators, wire tubes, china interior conduits, window and floor tubes, carved tubes for awnings, cornices, etc., guard wire suspension insulators, branch blocks, all kinds of switches, wall socket receptacles, key and keyless sockets, junction boxes, arc hanger boards, and many more china specialties too numerous to mention. A special feature is their "Syracuse" china fixture socket, which is easily connected up, and is superior to the metal shell, it being impossible to have a short circuit with the shell or cap; they always look neat and clean. A new Edison non-infringing china base with brass contact springs is another novelty shown. In order to convince people of the superior quality of their china, they exhibit two cups and saucers, which are in no way inferior to the ware found at the festive board. Over this very neat exhibit Mr. J. D. McIntyre presides in a most able manner.

THE EXPOSITION'S CALCULATING BOY.

THE Calculagraph Company are showing at the exposition their instrument in several different applications to various businesses. As its name implies, the instrument makes calculations and renders a printed record. Those in the exhibit show, not only the time of day, but elapsed time in hours and minutes, and also in minutes and seconds. Thus if in a telephone exchange a subscriber rings up an out-of-town correspondent, this instrument shows the exact time which elapses during the telephone talk. A section of a telephone switchboard, with a Calculagraph mounted as in actual service, forms a part of the exhibit. This machine is also applicable to manufacturers, where the exact time of a workingman may be shown, or in the case of a factory employing several hands at a certain rate per hour, another instrument is devised whereby, instead of figuring the hours and minutes, or fractions thereof, during which the workingman is employed, the result at a fixed rate of payment may be shown immediately in dollars and cents. This offers to the manufacturer an economical element, in that it dispenses with a time clerk, as the machine may be operated by an office boy, or by the workingmen themselves. But probably the most interesting variation of this device is shown in that form which is used in the hiring of row boats, horses or bicycles, for example, where the charge for service is a certain figure for the first hour and then something less than that for every hour thereafter. This machine is so adjusted that it automatically indicates the maximum charge for the first hour, and the minimum charge for the succeeding period, printing the result immediately in dollars and cents, in such a manner as to remove all possibility of mistake. It is a cleverly contrived piece of work and has attracted much attention to the space occupied by this company, which in itself is tastefully decorated with curtains and furnished with easy chairs.

PERSONAL.

MR. FRANCIS W. JONES, electrician of the Postal-Telegraph Cable Company, has contributed to the last monthly number of the "Transactions of the American Institute of Electrical Engineers," a most charming tribute to the memory of his old friend, Franklin Leonard Pope. It is written from the standpoint of close personal friendship, yet is impartial and even in its judgment and review. One may hunt long for a better piece of terse and sympathetic biographical work.

MR. HERBERT LAWS WEBB has in the "Illustrated American" of May 6 an admirable illustrated article on "The Switchboards of New York," being an account of what has been done to build up and maintain the telephone system of this city.

MR. HENRY G. ISSERTEL, E. E., has been appointed on the faculty of the National College of Electro-Therapeutics, at Indianapolis, Ind., in the chair of Practical Dynamic Electricity, a branch with which he is very familiar.

PROF. E. P. ROBERTS, of the Correspondence School of Technology, Cleveland, has been appointed consulting electrical engineer for an electric light plant to be installed in the Columbus State Hospital.

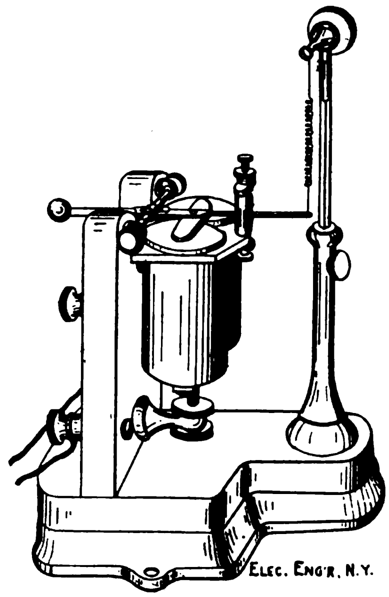
DR. WM. H. WAHL, for many years resident secretary of the Franklin Institute, has been honored by the French Government by election as "Officier d'Académie" with the decoration of the "palmes académiques" in recognition of his labors as secretary of the leading institute in America devoted to the advancement of the arts and manufactures, and of services rendered to the French Government.

TELEPHONY AND TELEGRAPHY.

EXPERIMENTS WITH MAC DONALD'S SENSITIVE-RELAY.

BY EDWARD P. THOMPSON, M. E.

THE instrument employed in these experiments is represented in the accompanying engraving, and consists of the ordinary Morse relay, except that the same is tilted so as to stand upright, while the tension spring is vertically set above one end of the armature lever, a weight being on the other, while the armature is between the spring and the fulcrum. Mr. A. D. MacDonald, of the Government Central



THE MAC DONALD SENSITIVE RELAY.

Telegraph Office, Melbourne, Australia, has communicated to me, for publication, the minutest details, description of the apparatus and the results, and I submit the following brief account which may be of interest to those interested in telegraphy. The tests were made on a line between Melbourne and Sydney, a distance of 577 miles, measured resistance 3,200 ohms, to which another 3,000 ohms was added, making a total of 6,200 ohms, equivalent to 1,100 miles of wire. The usual batteries were replaced by only one Leclanché cell, and the relay was wound to only 150 ohms of No. 32 wire. The weather was so unfavorable at the time that business had been delayed with the ordinary relays. Similar experiments were also carried on in the presence of Mr. Dwyer, officer in charge of the night staff, and operators Wulff, Healy and Bowe, and M. J. Cawley, testing officer. Telegraphic communication was held between Melbourne and Adelaide, as well as between Sydney and Melbourne, with perfect success.

PETITION AGAINST THE NEW CABLE VOCABULARY.

A petition is in circulation in this city asking for a reconsideration of the proposed official code vocabulary issued by the International Telegraph Bureau, at Berne. Following are some of the objections to the enforced adoption of the vocabulary: (1) The inadequate number of ciphers; (2) conflicting character of very many of the ciphers; (3) absence of necessity for changing existing conditions; (4) strong objection by financial and commercial bodies, bankers and merchants to adoption; (5) enormous expense attending revision of present cable codes; (6) apparent attempt to increase cost of cabling while limiting preconcerted ciphers to the number proposed; (7) wrong impression created by issuing the publication, many believing that the book is a complete code instead of a compilation of ciphers; (8) existing restrictions are sufficient to overcome attempts at irregularity on the part of merchants; (9) the use of names of common commercial articles, names representing days of week and name of months, of coins, of numerals, etc.

SOCIETY AND CLUB NOTES.

ANNUAL MEETING OF THE A. I. E. E.

The annual meeting of the Institute took place this week at the Electrical Exposition, where headquarters were furnished by the management. The business meeting for reports and election of officers took place on Tuesday. The following programme was arranged for Wednesday:

1. Teller's report of ballots received.
2. Report of Sub-Committee on Standards of Lights, by Dr. Edward L. Nichols, Clayton H. Sharp and Charles P. Matthews, of Ithaca, N. Y. A complete résumé of existing data upon this subject, together with original work by the committee, embracing standard candles, the Methven screen, the Pentane standard Hefner lamp, platinum standards, the Blondel arc standard, kerosene lamps, the acetylene flame, incandescent oxides, etc.
3. "Vacuum Tube Lighting." An opportunity will be offered for the discussion of the paper by Mr. D. McFarlan Moore, presented April 22.
4. "An Analysis of Transformer Curves," by Charles K. Huguet, of Pittsburg.

AFTERNOON SESSION.

Two o'clock, Wednesday, May 20, 1896.

5. "Effect of Temperature on Insulating Material," by George F. Sever, Ambrose Monell, and C. Langdon Perry, of New York City.
6. "An Experimental Study of Electromotive Forces Induced on Breaking a Circuit," by F. J. A. McKittrick, with introduction by Dr. E. L. Nichols, of Ithaca, N. Y.
7. "The Production of Electrical Energy for Office Buildings with Particular Reference to the Plant of the Chicago Board of Trade," by Bion J. Arnold, of Chicago.

THE NEW YORK ELECTRICAL SOCIETY AT THE EXPOSITION.

The 175th meeting of the society was held at the exposition on Monday, May 18, at 8 p. m., when the annual election of officers took place.

President Lieb received the members in the lecture room on the third story, after which special facilities were given for inspecting the chief features of interest, including a private view of the Edison fluoroscope and Röntgen ray exhibit.

Members and their friends wore the red and white badge on this occasion, distributed in the lecture room by the reception committee. There was a large attendance.

The ticket presented for election was as follows: President, Dr. C. E. Emery; vice-presidents H. L. Webb, W. W. Ker, Gano S. Dunn, M. Osterberg, A. L. Riker, W. Finn; treasurer, H. A. Sinclair; secretary, G. H. Guy. The society has had a most prosperous year, and now has close on to four hundred members.

REPORTS OF COMPANIES.

GENERAL ELECTRIC'S ANNUAL MEETING.

The annual meeting of the stockholders of the General Electrice Company was held at Schenectady on May 12. About 200,000 shares were represented. The directors elected are the same as last year, except that George Foster Peabody takes the place of Thomas K. Cummins, Jr. The board for the ensuing year is Oliver Ames, second, T. Jefferson Coolidge, Jr., C. H. Coster, Thomas A. Edison, Eugene Griffin, Gordon Abbott, F. B. Hastings, Henry L. Higginson, George P. Gardner, J. Pierpont Morgan, Robert Treat Paine, second, George Foster Peabody and C. A. Coffin.

INTERNATIONAL BELL TELEPHONE CO.

The annual meeting for the election of a board of directors to serve during the ensuing year was held May 12 by the stockholders of the International Bell Telephone Company (Limited), New York City. The following were chosen: Samuel D. Babcock, Gardiner G. Hubbard, Louis A. Von Hoffmann, Richard A. McCurdy, Charlton T. Lewis, Elisha S. Converse, William Mertens, Howard S. Randall and Louis A. Thebaud.

HELENA, MONT.—About $800,000 is to be spent in developing power electrically from the Missouri for Helena. President Hauser, of the First National Bank, and President Marlow, of the Montana National Bank, are interested.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED APRIL 28, 1896.

Alarms and Signals:—

AUTOMATIC ELECTRIC INDICATOR SYSTEM. G. E. Painter, Baltimore, Md., 559,088. Filed Feb. 26, 1895.
An armature lever serving as a switch arm, and provided with reversely inclined faces, an arm having similarly inclined faces for engaging with those on the lever, and operating as a tripping device, for mechanically moving said lever, and for confining it except when actuated by its magnets.

ELECTRICAL SIGNALING APPARATUS. G. E. Painter, Baltimore, Md., 559,089. Filed Feb. 16, 1895.
Similar to above.

SIGNALING APPARATUS FOR PRESSURE GAUGES. T. M. Gordon, Boston, Mass., 559,131. Filed July 10, 1895.
Details of Construction.

PROCESS OF HARDENING POSITIVE MASSES OF ACCUMULATORS. O. H. Weise, Poessnick, Germany, 559,155. Filed July 13, 1895.
Consists in placing the completed lead superoxid plate into a bath of glycerin.

Conductors, Conduits and Insulators:—

ELECTRIC CONNECTION. J. W. Marsh, Pittsburg, Pa., 558,971. Filed May 6, 1895.
A protecting covering, having mica compound or similar moldable insulating material molded directly to one or both of the members to form a tight joint.

CONNECTOR FOR ELECTRICITY CARRYING CABLES. D. E. Evans, Baltimore, Md., 559,168. Filed Nov. 4, 1895.
A tubular shell, enlarged centrally and provided with longitudinally disposed slots extending through opposite sides of the enlarged central portion, and means for fastening the ends of cables and soldering them together.

Distribution:—

MULTIPLE SERIES SYSTEM OF ELECTRICAL DISTRIBUTION. F. B. Badt, Chicago, Ill., 558,924. Filed Sept. 25, 1895.
Translating devices connected in multiple series between main and compensating conductors, an auxiliary source of electricity, an electrically operated controlling switch for connecting said source of electricity in circuit upon one or the other of the sides of said system, and a relay for automatically controlling the circuit through said controlling switch.

Dynamos and Motors:—

CURRENT STRAIGHTENING COMMUTATOR. C. Pollak, Frankfurt-on-the-Main, Germany, 558,983. Filed Aug. 28, 1895.
The combination of insulated hubs, having alternated segments and sleeve secured to the shaft between the hubs and to said hubs to hold the latter in place, said sleeve being insulated from the hubs.

ELECTRIC TRACTION MOTOR. J. F. Place, Montclair, N. J., 559,342. Filed March 16, 1894.
An aerial track motor for towing boats.

Electro-Metallurgy:—

METHOD OF ELECTROPLATING PURE NICKEL FROM FERRO-NICKEL ANODES. D. H. Browne, Brooklyn, O., 559,255. Filed July 20, 1893.
Consists in adding ammonia to the nickel salt solution until the latter is perceptibly smelling of ammonia, passing the current through the anodes, solution and cathodes, and introducing air in comminuted condition through the solution.

Lamps and Appurtenances:—

HANGER FOR ARC LAMPS. L. A. Scovil, Chicago, Ill., 558,989. Filed March 28, 1893.
A sleeve, a rod adapted to enter said sleeve, a lug or tongue being provided upon one of said parts while a longitudinal slot with inclined surfaces leading thereto is provided upon the other of said parts.

SAFETY ARC LAMP HANGER. E. P. Snowden, St. Joseph, Mo., 558,993. Filed Feb. 11, 1896.
Details of Construction.

ELECTRIC RUNNING LIGHT AND SIGNAL LANTERN FOR SHIPS. J. Barre, New York, 559,048. Filed Nov. 29, 1893.
Is provided with a cap at its upper end, carrying supports for two or more electric lights, said cap being rotatable with respect to the lamp fixture, whereby the electric lights may be brought successively into focus.

MAST ARM FOR ELECTRIC LAMPS. J. J. Shickluna, Buffalo, N. Y., 559,066. Filed April 29, 1895.
Composed of adjustable sections.

ELECTRIC LIGHT AND SIGNALING DEVICE. D. Misell, New York, 559,143. Filed Feb. 25, 1896.
The use of a spring-actuated circuit-maker which serves the double purpose of a handle for carrying the device, and a switch for controlling the current.

ELECTRIC LIGHT SHADE. H. Stenz, Faribault, Minn., 559,149. Filed June 27, 1895.
Comprises a clasp member for engaging the lamp, the shade member hinged directly to the clasp member and an arm to adjust the angle of the shade.

SOCKET FOR INCANDESCENT LAMPS. J. C. Tournier, Schenectady, N. Y., 559,232. Filed March 25, 1896.
Details of construction.

ELECTRIC LAMP. R. Hacking and G. Brand, Nottingham, England, 559,282. Filed July 20, 1895.
A combined protector and reflector axially rotatable upon the base piece.

Measurement:—

MILLIAMPERE METER. C. M. Hollopeter, Fostoria, O., 559,134. Filed May 31, 1895.
Especially adapted for the measurement of galvanic currents.

Miscellaneous:—

METHOD OF ELECTROLYTIC TREATMENT OF SOAP LYES. O. Lugo and H. T. Jackson, New York, 558,970. Filed Oct. 4, 1895.
The process of extracting the caustic alkali from spent soap lyes, which consists in subjecting the liquor to the action of a current of electricity applied by means of an anode of zinc retained in contact with the liquor, and a cathode separated from the anode by a porous partition.

ENDOSCOPIC INSTRUMENT. J. W. Daily, Boston, Mass., 559,122. Filed Aug. 21, 1895.
Consists of a detachable removable tube inclosing a small incandescent electric lamp.

MAGNETIZING BOX FOR HAIR PINS. C. A. Hussey, New York, 559,176. Filed Aug. 22, 1895.
A box having a form supporting the hair pins and a magnetized metallic part adapted to magnetize the hair pins.

ELECTRIC ATTACHMENT FOR PAPER RULING MACHINES. J. McAdams, Brooklyn, N. Y., 559,190. Filed Feb. 8, 1896.
Details of construction.

ELECTRIC BOILER. F. W. Schindler-Jenny, Kennelbach, Austria-Hungary, 559,223. Filed Oct. 2, 1895.
A ring-shaped heating body of refractory insulating material, containing resistance wires, and a casing in close contact with the said heating body.

ELECTRICALLY CONTROLLED CLUTCH. F. A. Weller, Boston, Mass., 559,240. Filed April 20, 1892.
A spanner co-operating with the screw to move the clutch and an electromagnet for moving the spanner into engagement with the screw.

ELECTRIC HEEL AND TOE PROTECTOR. J. A. Blair, New York, 559,254. Filed Feb. 27, 1896.
Consists of a heel socket and toe socket connected by elastic bands and separately containing positive and negative elements connected by a conductor.

PLOWING BY ELECTRICITY. F. Brutschke, Charlottenburg, Germany, 559,256. Filed Jan. 2, 1895.
A balanced tipping plow having an electric motor mounted thereon and a chain wheel actuated by the motor, in combination with a chain to be stretched across a field and anchored.

CANAL BOAT PROPULSION. W. Elmer, Jr., Trenton, N. J., 559,271. Filed Dec. 16, 1895.
An electric motor mounted on a movable truck is employed to operate a shaft having a sheave engaging with a traction cable.

CONTROLLING MECHANISM FOR LOCKS. R. A. Palmer, Boston, Mass., 559,308. Filed Aug. 14, 1895.
Employs a two-part spindle to operate by electromagnets.

Railways and Appliances:—

ECCENTRIC MOUNTING FOR ELECTRIC VEHICLE AXLES. E. W. G. C. Hoffmann, Charlottenburg, Germany, 558,953. Filed Dec. 27, 1895.
Details of Construction.

ELECTRIC RAILWAY CONDUIT. J. H. Munson, Chicago, Ill., 559,105. Filed March 5, 1895.
A slotted conduit having a recess or chamber, an insulating lining therefor, a metallic lining within the same, a plunger slidable within said metallic lining or barrel, and contact and switch devices provided in connection with said plunger.

ELECTRIC RAILWAY. R. M. Hunter, Philadelphia, Pa., 559,175. Filed July 8, 1893.

TROLLEY FOR ELECTRIC CARS. J. L. Foster, Waterbury, Conn., 559,275. Filed Sept. 11, 1895.
Means for lowering trolley when connection with the conductor is broken.

Regulation:—

ELECTRIC GOVERNOR. K. B. Miller, Washington, D. C., 559,187. Filed Feb. 25, 1896.
Consists in generating a periodic current and causing changes in the period of said current to react on the source of supply of power.

Switches, Cut-Outs, etc.

CIRCUIT BREAKER. M. J. Griffith, Wilkesbarre, Pa., 559,280. Filed Aug. 28, 1895.
Employs two pairs of contact pieces, one pair provided with carbon terminals and the other with metallic; and means are provided to separate the contact pieces suddenly and one after the other.

COMBINED SWITCH AND FUSE BLOCK. E. H. Montgomery, St. Paul, Minn., 559,340. Filed Oct. 2, 1893.
Consists of a rotatable block mounted upon a base, with suitable binding posts and circuit terminals for the line wires and dynamos.

Telephones:—

TELEPHONE AND CALLING SYSTEM. C. B. Smith, New York, 559,086. Filed Nov. 18, 1895.
Each conductor is normally apportioned to one station; calling devices and indicators or annunciators in each station.

TELEPHONE AND CALLING SYSTEM. C. B. Smith, New York, 559,087. Filed Nov. 19, 1895.
Similar to above.

TELEPHONE AND CALLING SYSTEM. J. G. Smith, New York, 559,088. Filed Feb. 11, 1896.
Similar to above.

TELEPHONE TRANSMITTER. F. A. Ray, Springfield, O., 559,106. Filed Oct. 2, 1893.
Pairs of diaphragms, comminuted resistance varying material mounted between and supported directly by said diaphragms, a cell containing said comminuted material, a single mouthpiece and air passages between said mouthpiece and each of said diaphragms.

ART OF TELEPHONING. D. H. Fitch, Cazenovia, N. Y., 559,274. Filed Nov. 29, 1895.
A normally polarized electromagnet, an auxiliary mechanism actuated thereby, and a multiple connection between the magnet coils and line terminals.

TELEPHONE SWITCHBOARD. H. M. Fisk, Austin, Ill., 559,348. Filed May 27, 1895.
Combination of an electromagnet and a drop or shutter in front of it with connecting or extension points in front of the shutter, and a thin plug attached to a flexible cord and made to lock into the connectors.

ELECTRICITY IN A BROOKLYN HOSPITAL.

The Long Island College Hospital will have in its new Polhemus Memorial Building a course of study in electro-therapeutics, to be carried on with the aid of the latest and best apparatus.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE PROSPERITY OF THE TRIUMPH ELECTRIC COMPANY.

The Triumph Electric Company, of Cincinnati, issues the following list of its April business:

Caledonia Electric Light and Power Company, Owosso, Mich., one 150 kilowatt, 550 volt generator, direct connected to a Fischer engine. Owosso and Corunna Traction Company, Owosso, Mich., two 65 kilowatt, 550 volt generators, belted. Lane & Bodley Company, Cincinnati, O., one 100 kilowatt belted generator. Studebaker Bros. Manufacturing Company, South Bend, Ind., one 65 kilowatt belted generator. Hot Springs Hotel Company, Hot Springs, Va., one 55 kilowatt generator direct connected to Buckeye engine; one 30 kilowatt belted generator. Krippendorf, Dittman & Company, Cincinnati, O., two 65 kilowatt generators direct connected to a Willans engine. J. M. High & Company, Atlanta, Ga., one 45 kilowatt belted generator. U. S. snag boat "E. A. Woodruff," Cincinnati, O., one 10 kilowatt generator direct connected to vertical engine. A. H. Ely, New York City, one 80 kilowatt type W generator direct connected to an Ames engine. Sol. Sayles, New York City, one 25 kilowatt generator direct connected to a Woodbury engine. Nordberg Manufacturing Company, Milwaukee, Wis., one 30 kilowatt generator belted.

THE NEW C & C MULTIPOLAR DYNAMO.

We illustrate in the accompanying engravings the new type of multipolar generator built by the C. & C. Electric Company, of New York, which has been designed in accordance with the most approved electrical practice and with special reference to direct connection with the driving engine. With this end in view the design of the machine has been such that the dynamo can be driven direct by the best class of engines in contradistinction to a design which just barely permits of the machine being connected to engines running at very high speeds.

As will be seen, the simplest mechanical construction has been adopted. The entire field magnet frame, including the pole pieces, is cast in one piece, of steel, without a single joint, and the magnetic leakage is so low that no magnetism can be found in the iron of the engine. This avoids the baneful effects of stray magnetism which is frequently found to affect the operation of the engine governor.

Each field coil is independently wound on a separate, detachable bobbin, so constructed to be open to air currents, both inside as well as outside, and as a result the regulation is not appreciably affected by any variation of the resistance of the coils during a run, no matter how long; besides, with this construction the field is economical, and a burnout practically impossible.

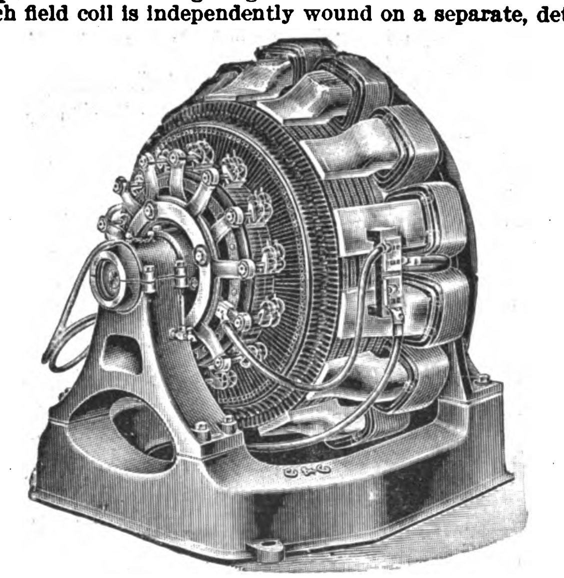


FIG. 1.—THE NEW C & C MULTIPOLAR DYNAMO.

The armature is wound with endless flat ribbons or bars, thus reducing the air gap to a minimum and guaranteeing windings against slip, at the same time allowing of easy rewinding of a coil, in case of necessity, by even a novice.

The brushes employed are of graphite, and thus self-lubricating, which, as is well known, is only possible in a dynamo where the current is of low density in each brush, such as is the case in this type of machine; the result of this practice is that the commutator does not cut or wear.

Particular care has been bestowed upon the ventilation of the machine, and as a result even under the usual practice of overloading, the machine runs cool, and a heavy emergency overload can be carried with safety. The insulation of the machine is one million ohms from conductor to frame.

The regulation of the machine is automatic within less than 2 per cent. with extreme variations of load. No brush movement whatever is required up to an overload of 20 per cent. The commercial efficiency of the machine is from 90 to 95 per cent., depending on the size of the machine, which efficiency is maintained nearly throughout the entire working range of

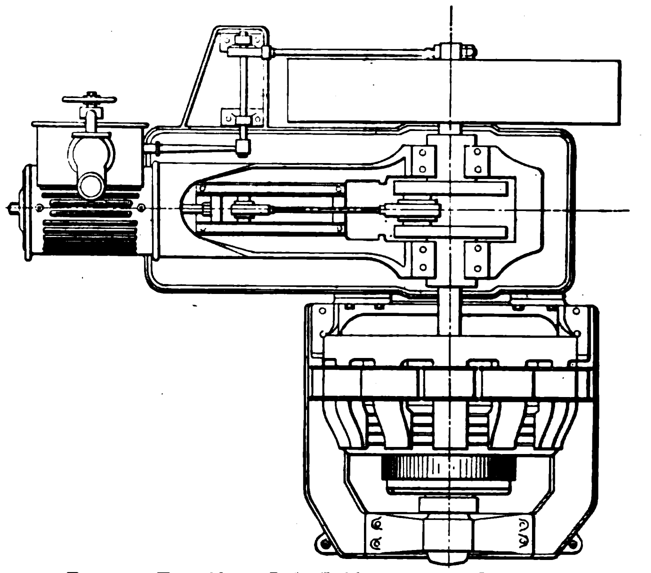

FIG. 2.—THE NEW C & C MULTIPOLAR DYNAMO.

load. These machines are built in sizes of 25, 50 and 100 kilowatts. Our engraving, Fig. 1, shows the dynamo in perspective, and Fig. 2 is a plan view illustrating its connection direct to the engine. It will be noted that no outboard bearing is required, thus economizing space and reducing the cost.

3,600 H. P. FEED WATER HEATERS.

The Kensington Engine Works, Limited, of Philadelphia, Pa., have just closed a contract with the William Cramp & Sons Ship and Engine Building Company, for two of their large water tube heaters. They will be 38 inches in diameter by 20 feet long, and tested for a working pressure of 150 pounds. These heaters will be installed in the power plant at Washington, D. C., for the electric trolley line between Baltimore and Washington.

FREE CUBA.

There is no need to go to Cuba to ascertain all the facts as to the war for freedom in the ever-rebellious isle. All you have to do is to secure the latest advertising card of the American Electrical Works, of Providence, R. I. It gives all the data in a pretty and effective way.

INTERIOR TELEPHONES AT NARRAGANSETT PIER, R. I.

What is said to be the largest interior telephone system in the world is being installed by the Wilson Bates Electric Company for the Hotel Matthewson, Narragansett Pier, R. I. The telephones for this work are being furnished by De Veau & Co., of 32 and 34 Frankfort street, New York City.

BORING STEAMBOAT ENGINE CYLINDERS BY ELECTRIC MOTOR.

The Vulcan Iron Works Company, of Toledo, O., Alex. Backus, president, recently performed a very rapid piece of work on a steamship with the aid of an electric motor, in the way of boring the cylinders. They used a one horse-power

Commercial Electric Company, Indianapolis, Ind., 500-volt motor, the speed of which is 2,200. The bar was geared back from this thirty-six times. They bored one 48-inch diameter cylinder 42 inches deep in 9 hours; one 30 inches by 42 inches in 7½ hours; one air pump, 20 inches by 24 inches, two cuts, in 5 hours; one steam chest, 14 inches by 44 inches, in 5½ hours; one steam chest, 12 inches by 34 inches, in 3½ hours. The motor gave them a very steady motion and enabled them to make a perfect job. It is one that attracted considerable attention here, and the firm have received very favorable comment on the work. The work was done on the Wabash Line Steamer S. C. Reynolds.

NEW DEPARTURE IN AUTOMATIC FIRE ALARMS.

The Electric Heat Alarm Company, 145 High street, Boston, Mass., has brought its thermostat to a very high degree of perfection. It has been installed in direct connection with street fire alarm boxes for over a year without trouble, the latest connections having been made at Rockland and East Weymouth, Mass. In this unique system the transmitter in the testing and recording apparatus is connected in series with the fire alarm boxes, and made to strike a certain number, like the street fire alarm system. In connection with this is a box on the outside of the building. Should a fire occur in the immediate vicinity of the factory after it is closed, a person discovering the fire can by the simple act of breaking the glass in this box give an alarm to the department. The department immediately know that there is a fire in the factory or nearby. When they arrive at the factory and find that the bell on the front of the building is not ringing, and the annunciator drop not indicating a certain section of the factory, they know that the fire is in some house nearby. This practically gives the town another street fire alarm box, and as most villages have only a few boxes, the system is highly appreciated by the citizens.

The Electric Heat Alarm Company is making arrangements for connecting this system direct with a successive non-interference fire alarm box made by the United States Fire and Police Telegraph Company, of 246 Washington street, Boston.

The Electric Heat Alarm Company would be pleased to have parties interested call and see the practical working of its system.

From firms in Bangor, Maine, and Milford, N. H., most flattering indorsements have been received, of this system, which is so unerring in its operation. Below is a copy of a letter received from Morse & Kaley Manufacturing Company, Milford, N. H., which speaks for itself:

Milford, N. H., February 18, 1896.

Electric Heat Alarm Company, Boston, Mass.

We wish to pay our tribute to your Thermostat Fire Alarm. We had a slight fire in our balling room last night and it worked to a charm, as it went off before the sprinklers, thus allowing time for our men to get there to prevent unnecessary damage by water. We congratulate you on its successful workings.

Yours very truly,
(Signed) MORSE & KALEY MFG. CO.
Dic. by F. E. K.

ELECTRICITY IN PENNSYLVANIA MINES.

One of the most recent coal mine plants is that which will be installed by the Scranton Electrical Construction Company at the Mount Pleasant Colliery, owned by Mr. W. F. Smith, of Scranton. The electrical portion of the plant will consist of one four-pole 100 kilowatt, 650 revolution, 250 volt generator, and one electric locomotive from the works of the General Electric Company. The locomotive will be required to haul an average of about 400 cars daily from the counter chutes located along the main gangway. The average length of haul one way is about 3,000 feet. In addition to the haulage plant the coal company will operate from the same wire several rotary coal drills in the same vein.

Another interesting electrical plant is being installed by the Lehigh Valley Coal Company, which operates a large number of collieries in the anthracite district as well as many semi-bituminous mines in the Clearfield region. The plant consists of one General Electric 150 kilowatt, 550 volt generator furnishing current to one duplex double acting Jeansville mine pump, and one 100 horse-power Lidgerwood friction cone clutch single drum hoist. Both of these machines will be set about 6,000 feet from the generator in the center of a long slope in the main coal seam. The circuit to the hoist and pump will be carried about 5,300 feet above ground on a pole line, and will then pass down a vertical bore hole 350 feet deep. This part of the line will consist of an iron armored cable, and will be suspended solely by the iron armor.

The pump will have a capacity of 600 gallons per minute, and will lift water through a vertical bore hole to a height of 350 feet. The average work of the hoist will be the hauling of about fifteen tons up an 8 degree slope at an average speed of 500 feet. The hoist will also be required to lower about five tons down the same slope. The advantages of electricity are strikingly illustrated in this plant. If electricity had not been selected for the hoist and pump work, it would have been necessary to carry the steam some distance through the mine, and provide special bore holes and condensers for the disposition of the exhaust steam.

A TELEPHONE PLANT FOR FORT WAYNE, IND.

The Western Telephone Construction Company has just closed a contract with the Fort Wayne Telephone Company, Fort Wayne, Ind., to furnish a 2,000 equipment, 1,000 of which are to be shipped immediately. This is to be the "Queen" independent telephone exchange system in America.

UNDERGROUND CABLE EXPERTS.

Mr. William Arnot, Mr. Philip Martin, Mr. Michael Duffy, and Mr. John McKenna, well-known underground cable experts, have resigned from the Standard Company and have made arrangements with the National Underground Cable Company. Each of these men has had a long experience in underground and aerial cable construction work of all kinds, including street railway, electric light, telephone and telegraph cable, and are well known for their ability in their lines and are a valuable addition to the National Company's already large force.

The National Company's Construction Department is now one of the largest in the country and is in a position to handle any work, no matter how large, with promptness and dispatch.

THE HOGAN BOILER COMPANY.

The Hogan Boiler Company have published a pamphlet in which the excellent points of their water tube boilers, stationary and marine, are set forth. "Six reasons" are given why the Hogan water tube boilers deliver dry steam, and do not "prime" or foam. Each steam producing tube passes above the water surface in the steam drum; the effect of ebullition is removed from beneath the water surface; water cannot be entrained with the steam through the perforated plates of the steam extractor; small globules of water within the steam extractor are evaporated; the extractor is located in the steam drum where the highest temperatures exist; and the steam separators are not necessary with the Hogan water tube boilers. The company claim that in using their boilers there is no scale on the heating surface, the mud drums collect all the sediment, the efficiency is increased greatly above the normal, and the yearly coal bills are reduced by thousands of dollars.

THE ALUMINUM FLUOROSCOPE.

Mr. Henry V. Parsell, Jr., writes us as follows:

I have tried the aluminum fluoroscope, and should judge that it is about three-quarters (¾) as effective as the Aylsworth & Jackson instrument. There is an irregularity in the luminosity of the screen. To make sure I have tried several other observers who agree with me in the foregoing statements.

CARD GENERATOR FOR THE OHIO STATE REFORMATORY.

The board of managers of the Ohio State Reformatory have awarded the Card Electric Company, of Mansfield, O., the contract for two direct connected multipolar generators, capacity 66 k. w. each, speed 250 revolutions per minute, for use in the reformatory at Mansfield, for lighting purposes. The generators will be direct coupled to Ball engines. Competition in the above case was quite keen, and the company consider the capture of the contract quite an achievement.

MR. M. M. WOOD, the well-known electrical engineer, of Chicago, Ill., has completed the long-distance transmission power plant for the Lowell Water and Light Co., of Grand Rapids, and the company may congratulate themselves in having employed so good a man to engineer their work. Mr. Wood has the reputation of being among the best as an engineer, and it is with pleasure we credit him with constructing the third longest power transmission in the United States, that from Lowell to Grand Rapids, Mich, a distance of twenty miles, and delivering 200 horse-power.

NEW ENGLAND NOTES.

MR. C. G. PERKINS, President of the Perkins Electric Switch Manufacturing Company, Hartford, Conn., made a short business trip to Chicago recently, and made his headquarters at the Western Office of the company, in the Monadnock Block.

GEO. H. MORRILL & CO., of Boston, Mass., manufacturers of printers' inks, are erecting a building over some new stills in addition to their already extensive plant. This building will be of steel construction throughout, having steel siding, roof trusses and covering, and the interior platforms will be constructed in the same manner. The Berlin Iron Bridge Company, of East Berlin, Conn., have the contract for furnishing the complete building.

WESTERN NOTES.

THE LAKON CO., manufacturers of the Lakon transformer, have removed their Chicago office, which is in charge of F. S. Terry, to suite 1,509, 1,510 and 1,5011 Monadnock Block.

THE SUNBEAM INCANDESCENT LAMP CO., Chicago, have removed their offices from the Title and Trust Building to suite Nos. 1,509, 1,510 and 1,511 Monadnock Block, where they will have much more commodious quarters.

THE CUTTER ELECTRICAL AND MANUFACTURING CO., manufacturers of the C. S. flush push switches and the I. T. E. circuit breakers, have removed their western office to suite No. 1,509, 1,510 and 1,511 Monadnock Block, Chicago.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, of St. Louis, have issued recently two neat and business-like catalogues, one relating to their transformers and the other to their switchboards. Both are full of data, cuts and appropriate information.

MR. S. F. B. MORSE, the Marquette Building, Chicago, General Western Agent for Day's Kerite, recently secured the contract for the wiring of the new Great Northern Hotel and Theatre with the well-known Kerite wire. As usual there was some brisk competition for the contract, and after a sharp fight of considerable duration Kerite came to the fore.

THE METROPOLITAN ELECTRIC COMPANY have just taken the agency for the Diehl Manufacturing Company, of Elizabethport, New Jersey, and will carry in stock a complete line of their ceiling fan motors. The Diehl Manufacturing Company are the oldest manufacturers in the country of ceiling fan motors in their various shapes and styles, and the Metropolitan Electric Company are fortunate in securing this agency.

THE ELECTRICAL APPLIANCE COMPANY, Chicago, state that they are well prepared for the fan motor season with a very complete line. They still retain the agency for the celebrated Meston line of alternating current apparatus. The agency for the celebrated Dayton ceiling and column fan has been secured for this season. The new Acme fan motor manufactured by the Appliance Company will also be a specialty for this season. It is made in both single and three speed and is a high grade machine.

MR. JOHN GORMAN, for twenty years practical electrician and dealer in electrical apparatus in St. Paul, will represent the Metropolitan Electric Company in handling N. I. R. wire, Metropolitan lamps, "Mac" tape, P. & B. Compound varnish, etc. Mr. Gorman is prominently identified in electrical interests in St. Paul and Minneapolis, and has done a large share of the electrical work in that section during the last twenty years. The Metropolitan Company can be congratulated in getting Mr. Gorman to handle their goods.

THE AKRON SMOKING PIPE COMPANY, of Akron, O., are now manufacturing Fenton insulating tubes, cleats and knobs in a variety of sizes to meet the demands. These goods are composed of a hard, vitreous substance, uniformly glazed, which the company thoroughly warrants in regard to absorbtion and conductivity. The process of manufacture employed by this company enables them to produce perfect shapes of any length, and tubes of large dimensions will be guaranteed as to their straightness. Tubes are made with white or brown glaze or of porcelain.

THE TRUMP MANUFACTURING COMPANY, of Springfield, O., issue a large and handsome pamphlet devoted to their Trump model turbine, which is in widespread use, and is an effective piece of apparatus for the utilization of water-power. The pamphlet contains illustrations of its use. The company build also the Leffel wheel in all sizes, and the double discharge turbine peculiarly suitable for high heads. They are also largely engaged in the production of penstocks, piping, etc., mill gearing, shafting, etc. The class of work is important, and the grade is of the highest.

THE FARR TELEPHONE AND CONSTRUCTION SUPPLY COMPANY, 342 Dearborn street, Chicago, are now distributing their latest catalogue, which is the third and largest that has been published by this enterprising concern. It is very tastefully done, with a bright paper cover, on the front of which is shown a view of the exterior of the company's store. The catalogue contains thirty-two pages of illustrations and reading matter pertaining to the large and varied stock of telephone goods which they carry. As the prices of all the goods are mentioned, and also full particulars regarding terms are given in a very lucid manner, all who are interested in telephone matters will find it a most convenient book to have at hand.

NEW YORK NOTES.

THE WARD LEONARD ELECTRIC CO. will make various kinds of electrical apparatus at Hoboken, N. J. Its capital stock is $100,000. Among those interested are H. Ward Leonard, W. Pelzer and D. H. Driscoll.

THE VITASCOPE COMPANY, of New York City, has been formed to deal in vitascopes, kinetoscopes, phonographs, and similar machines. Capital, $60,000, and directors: Norman C. Raff, Frank R. Gammon and James H. White, of Brooklyn.

MR. F. W. DARLINGTON, formerly chief engineer for the Philadelphia Traction Company, having offices at the Drexel Building, Philadelphia, and 111 Broadway, New York, has removed the latter office to 114 Nassau street, New York. Mr. Darlington will divide his time between the two cities.

THE DICKINSON ELECTRIC SUPPLY COMPANY will remove May 1, from 150 Nassau street to 141 Broadway. This is the company handling the "Alpha" sign lamp, and their new location gives them better office accommodations, more commodious quarters and better shipping facilities than at present afforded them.

MESSRS. LEVY & MEYERS have recently been appointed agents for the well-known Starbuck & Davidson exhaust fans, and are doing business under the name of The Cable Electric Construction Company, No. 621 Broadway. They are prepared to furnish estimates on all kinds of electrical work and to supply and install the above-named fans.

THE AMERICAN ELECTRICIAN COMPANY, of New York City, has been formed to edit and publish magazines, newspapers and books and deal in electrical appliances. Capital, $50,000, and directors: Emmet L. Powers, of Chicago, Ill.; W. D. Weaver, of New York; Elmer E. Wood, of Brooklyn; Edward Caldwell, of Plainfield, N. J. ,and C. E. Whittlesley, of Madison, N. J.

MR. EDWARD F. WHITE has recently opened offices at 136 Liberty street, New York, and is conducting a general mechanical engineering business, giving special attention to the designing and operation of manufacturing works. Mr. White also makes a specialty of introducing labor-saving machinery for handling various materials and products of manufactories, and recommends special arrangements for increasing the economy of operation of steam plants and other machinery.

cialty for this season. It is made both single and three-returned from South Africa full of interesting reminiscences of travel. He is a shrewd and close observer, and as he was in Pretoria when the "Raiders" were in jail, he speaks on recent events with the authority of an eye-witness. Mr. Shippy is a "liberty man" if ever there was one, but he is decidedly not an advocate of the Boers, to whom a self-governing American is just as obnoxious as a gold-seeking Englishman.

THE UNITED STATES PROJECTILE COMPANY, of Brooklyn, N. Y., are erecting a new building to meet the large demand for their products. The new building will be 100 feet wide and 450 feet long, of steel skeleton structure throughout. The steel work for the building has been designed and will be erected by the Berlin Iron Bridge Company, of East Berlin, Conn. The trusses have a clear span of 100 feet, and the general construction is such that it will make one of the finest buildings of the kind in the country.

THE SOUTH AMERICAN LIGHT, POWER AND TRACTION COMPANY, of Lima, Peru, has just placed a contract with the General Electric Company, of New York, for the installation of a 5,000 h. p. electrical plant. The dynamos will be erected at the waterfalls eleven miles from Lima, and the electric power generated will be transmitted to the city, where it will be used to operate the surface railways and electric lights and furnish to the public generally such electric power as may be required. This will be the largest installation of electricity in South America.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. MAY 27, 1896. No. 421.

ELECTRIC LIGHTING.

THE RECONSTRUCTION OF THE PLANT OF THE CHICAGO BOARD OF TRADE.[1]

BY BION J. ARNOLD.

THE plant involves a number of departures from the standard lines of office building engineering, and if the results of the operation are as successful as it now seems, after running a short period, the annual expenses of the operation of the plant will be reduced from $25,000 to $15,000, and consequently the results obtained from its operation will be watched closely by the members of the Board of Trade who have the matter immediately in charge.

The writer believes that all the energy required to produce motion and light in an office building should be developed in one set of steam engine cylinders and on one generator. This set of cylinders, together with the working parts of the engine and its generator connected directly to it, constitute the unit which produces the energy of the plant, and this unit should be made to work at its maximum economical load throughout its entire period of operation, while the energy from the unit should all be utilized during its running time. Having this idea constantly in view, the designer of this plant has planned to follow it out as closely as possible.

It became apparent after an examination of the old plant that if the steam pressure could be increased to 125 pounds per square inch, instead of 75, so as the get the advantage of drier steam, and all the pumps in the plant which were consuming steam full stroke eliminated, and the energy of the plant produced by a compound condensing engine running at an economical load, a large reduction in the operating expenses of the plant could be effected. The adoption of a compound condensing engine to work under this increased steam pressure was a natural sequence which enabled the energy to be produced with the least possible coal consumption. After quite an extended investigation it was decided to supplant the hydraulic elevators with horizontal screw multiple sheave elevators, as the investigation showed that these machines could be operated for considerably less money per car mile than the hydraulic machines, under the conditions which existed in this plant. The operation of these elevators in practice has fully proven the correctness of this position. They have been in operation about four months now, on an average consumption of 4¼ kilowatt-hours per car mile.

The general plan of the plant is as follows:

The installation consists of the following: Five 66 x 16 feet horizontal tubular boilers, designed to carry 125 pounds pressure per square inch; two 150 horse-power horizontal compound condensing engines running at 275 revolutions per minute, each directly connected to a 75 kilowatt direct current generator, under a special system devised by the writer, which permits of either or both generators being driven from either engine. Four horizontal 30 horse-power multiple sheave elevators; six 10 horse-power electric motors, five of which operate ventilating fans, and one the machinery in the machine shop. There are also sixty-five 1,600 ampere-hour storage cells, and the necessary switchboard and connections for the handling of the above machinery. One of the compound steam pumps has been retained in order to keep the tank on the roof of the building supplied with water for use in the wash-basins, closets, etc. It may prove advantageous in the future to substitute for this an electrically driven pump, but it has been thought best not to discard the old one at present, inasmuch as it is already on hand.

The losses in wiring circuits of the building are computed as follows: Between generator and switchboard, one-half of one per cent.; between switchboard and center of distribution two and a half per cent.; from center of distribution to secondary mains, one per cent.; between secondary mains and lights, one per cent.—making the total loss between generator terminals and lights five per cent.

Fig. 2 represents largely diagrammatically the switchboard of the plant. From this it will be noticed that the plant is designed for three generators, but two of which are now in operation, as they are sufficient for the work. In the main lighting bus-bar is placed the recording wattmeter, which registers all the energy delivered from the generator to the light and motor portions of the plant. In the elevator bus-bars is placed another recording wattmeter, which registers all the energy delivered to the elevators from the lighting bus-bars. With this arrangement and the means available in the plant for measuring the amount of coal and water consumed, the operators are enabled to keep accurate daily records of the cost per kilowatt of the energy produced and delivered by the plant.

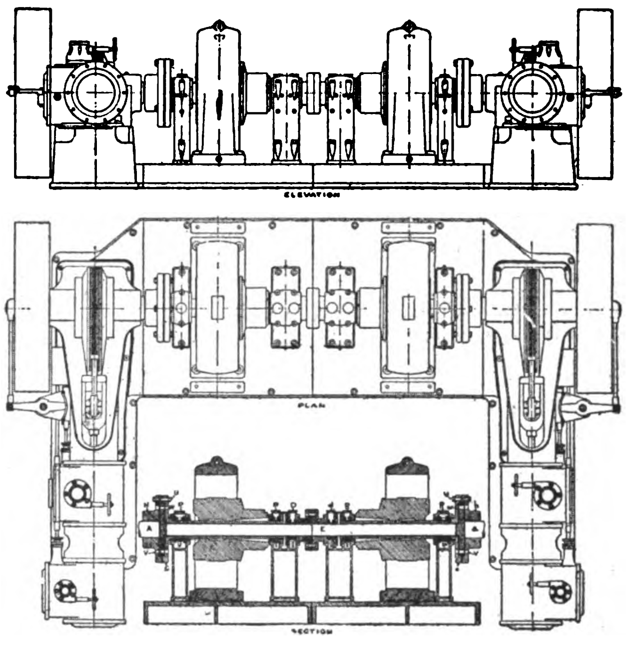

FIG. 1.—THE ARNOLD METHOD OF ENGINE AND DYNAMO CONNECTION, BOARD OF TRADE PLANT, CHICAGO.

The generators are connected to the board by means of two switches, one of which is a triple-pole double-throw switch, and is arranged so that when thrown into the upper position it connects the generator to the elevator bus-bar, using the compound winding of the generators. This arrangement permits the generator to operate the elevators and take care of the variable load without the use of the batteries. When the same switch is thrown in its lower portion, the circuits are so arranged that the compound or series winding of the generator is cut out, and the equalizer connection from the generator becomes the positive connection, and the generator is connected to the elevator bus-bars shunt wound, thus eliminating its series winding. With this arrangement, the generators and the batteries are run in multiple on the elevator load.

Referring now to the right hand part of the board, which is the storage battery proper, the operation is as follows: Under normal conditions, any elevator is operated shunt wound in parallel with the batteries by closing its corresponding switch downward. In this position whatever number of batteries are

[1]Read before the American Institute of Electrical Engineers, New York, May 20, 1896. Abstract.

being operated in this series, are in parallel with the generator. The hand regulator is placed in the position indicated to enable the operator to cut in a sufficient number of cells in parallel with the generator, so that the cells will be constantly charging during the time of operation of the elevators, except at the temporary moments of overload caused by an excessive

winding used when the batteries are being run in parallel with the elevators and lights. When the demand for current from the cells is great, as, for instance, when the elevator load is severe, the electromotive force of the number of cells in parallel with the elevators necessarily drops, consequently the electromotive force of the number of cells in parallel with

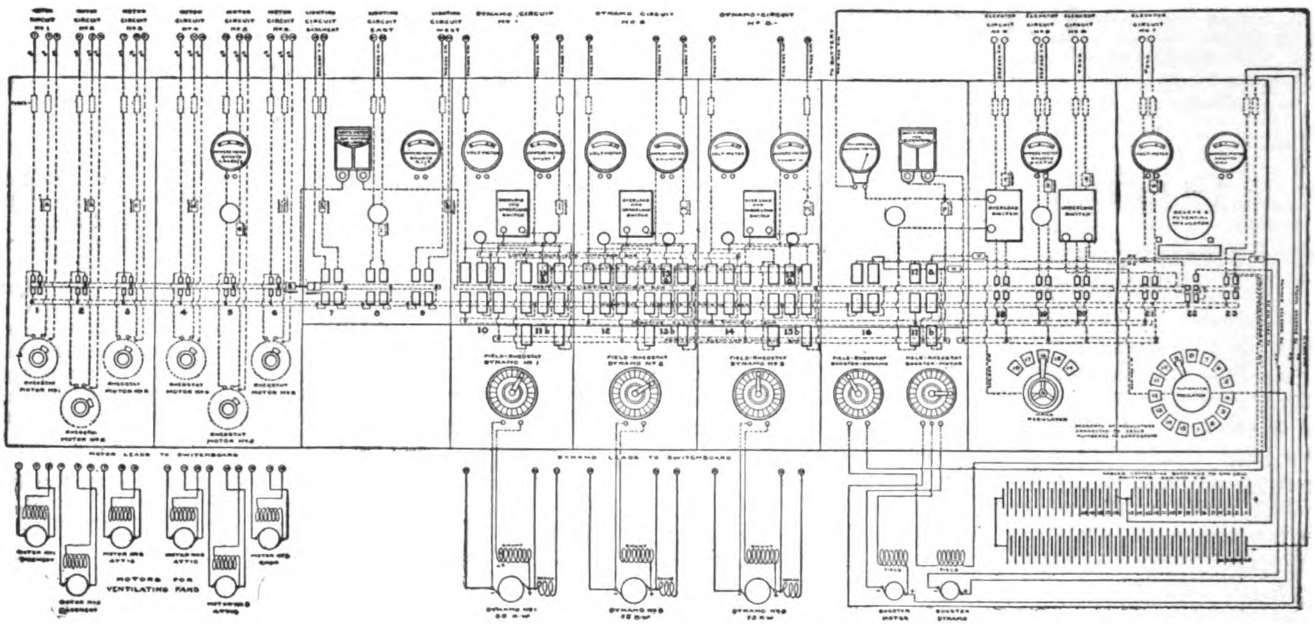

FIG. 2.

demand for current by the elevators. When this pull from the elevator occurs, the batteries respond and take the surplus load from the generator. With this arrangement, about fifty of the cells will be kept constantly charged, and in parallel with the elevators. In case the amount of current entering the cells is excessive between the intervals of heavy load on the elevators, the hand regulator is adjusted so as to cut in one or more cells until the current becomes reduced to the proper amount for the batteries; and, on the other hand, if the amount entering the cells is not enough to keep them properly charged, the hand regulator is adjusted so as to cut out a number of cells until the proper amount of current is reached.

In order to operate the batteries in parallel with both the

the lighting bars, which includes all the cells working with the elevators, and a few of the regulating cells, would correspondingly drop, and some means must be provided to hold up the voltage of the lighting bus-bars. This is accomplished by means of the automatic regulator, which is controlled by a solenoid switch, shown in the upper right hand portion of the diagram.

To charge all the cells in series from one of the main generators, it is necessary to increase the electromotive force a sufficient amount to overcome the total voltage of the cells. This is done by placing the generator portion of the booster or motor-generator in series with the main generator.

The method of connecting the engines and generators is

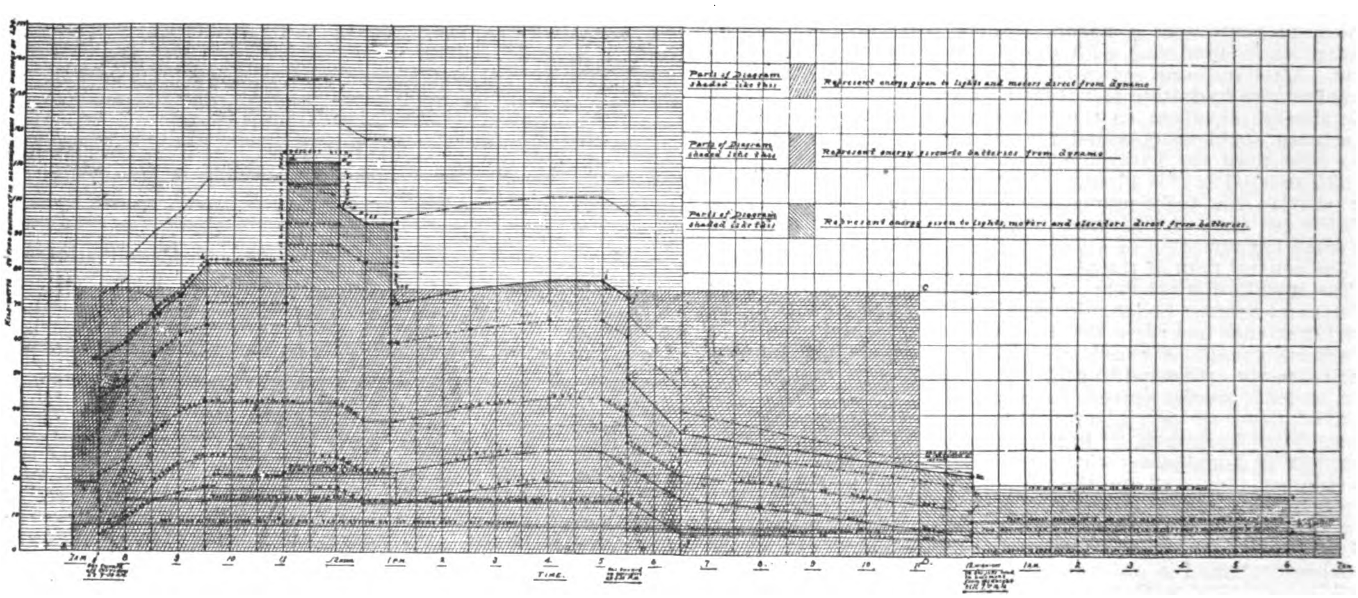

FIG. 3.—DIAGRAM SHOWING DISTRIBUTION OF LOAD BETWEEN DYNAMO AND STORAGE BATTERY IN CHICAGO BOARD OF TRADE PLANT.

lighting and the elevator bus-bars at the same time and maintain a practically constant voltage on the lighting bus-bars, it is necessary to operate the generators shunt-wound instead of compound-wound. As before shown, the switches are so arranged that the compound winding of the generators can be utilized when the batteries are not in service, and the shunt

shown in Fig. 1, and represents a system planned by the writer, which enables a direct coupled plant to be so built as to have the advantage of an independent unit when operating under normal conditions, and all the advantages of a belted plant in case of accident to any particular part of the plant. The cut shows the plan, elevation and section. Referring to

the sectional view, A a represents the ends of the engine shafts, which carry discs, H h. The generators are mounted upon hollow sleeves or quills, which are supported in independent bearings, P P and p p. The ends of these quills are enlarged to form flanges corresponding in diameter and thickness to the engine flanges. Between the shafts of engine, A a, extends an auxiliary shaft, E, (coupled at its center, in this case, to permit half of the plant being put in operation before the other half is ready), and carried in independent bearings, D d. This shaft, E, carries at each end circular discs, which in this case are forged solid with the shaft. Under normal conditions shaft E does not revolve, but lies passive in bearings, D d, and the engines drive the generators direct coupled, by inserting the bolts, U u, three of which, spaced 120 degrees apart, are used in each coupling. It is now evident that each engine is operating an independent direct coupled generator without revolving any more shafting or machinery than is usual in ordinary independent direct coupled plants, inasmuch as the quills which surround the auxiliary shaft, E, do not come in contact with it, but have a clearance of one-quarter of an inch all around it. By a very simple manipulation the right hand generator can be driven from the left hand engine, or both generators from either one of the engines. By using compound engines, so designed that by working high pressure steam in the low pressure cylinder, one engine can be made to double its power for a few hours. The plant has thus the total generator capacity available at all times and allows one engine to be in reserve for repairs, thus doing away with the investment of the third unit, which is usually carried in such plants for safety. The system, when used without the battery auxiliary instead of being provided with bolted connections as here shown, is provided with magnetic clutches, which permit the generators to be brought up to speed as motors, and thrown in connection with the engines without stopping either engine. This makes it possible to connect either generator with either engine without shutting down the plant in any part. With such an arrangement, with the engine and generators equal to the maximum capacity of the plant, and battery auxiliary equal to one-third the capacity of the plant, any office building can be operated in the most economical manner, according to the writer's belief.

The engines are operated during the summer compound condensing, by using a cooling pan system and siphon condenser. With this arrangement the condensing water is cooled by means of the 72-inch ventilating fan, which is in operation during the entire sixteen-hour run of the plant, and is used for ventilating the building. It was thought advisable to utilize the air from this fan for cooling the water, inasmuch as the energy for driving the fan had to be produced, and utilizing the air from the fan would not entail any additional expenditure of energy upon the plant over that required under ordinary conditions.

Fig. 3 represents the load diagram of this plant. The parallelogram, A, B, C, D, representing the total capacity in kilowatt hours of one of the generator units, assuming that the unit starts at 7 o'clock a. m. and operates until 11 o'clock p. m. The line, a, b, c, d, e, f, g, h, i, j, k, l, m, represents the load line, or energy required by the building during the same period. That portion of the diagram shaded with lines inclining to the right at an angle of 45 degrees represents the amount of energy passing into the batteries, while the portion of the diagram represented by shade lines inclining to the left at an angle of 45 degrees represents the amount of energy delivered from the batteries. It will be noticed that from 11 p. m. until 7 a. m. the entire load of the plant is operated by the batteries alone. With this arrangement but two shifts of labor are required, one operating from 7 a. m. until 3 p. m., and the other from 3 p. m. until 11 p. m. From 11 p. m. until morning during the winter the watchman acts as fireman for the boilers to maintain the steam heat in the building.

STANDARDS OF LIGHT.[1]

BY EDWARD L. NICHOLS, CLAYTON H. SHARP, AND CHARLES P. MATTHEWS.

THE sub-committee appointed to investigate the subject of a suitable standard of light for photometric purposes has been engaged upon preliminary experiments, and upon the collection of data concerning existing standards, and also such other sources of light as may be regarded as possible substitutes for the present standards. The committee is still at work upon these preliminary experiments, but it has reached a stage when it seems desirable to make some report of progress.

The following sources of light have been in use in photometric work for a sufficient length of time to enable various observers to become acquainted with their merits and likewise with their imperfections. (1) the Carcel lamp, (2) the British standard candle, (3) the German standard candle (Vereinskerze), (4) the Methven screen, (5) the Hefner-Alteneck amylacetate lamp, (6) the Harcourt pentane standard, and (7) the Harcourt pentane lamp. In addition to these there have been suggested the Violle platinum standard, various luminous gas flames, the crater of the positive carbon in the arc, and the surface of a strip of platinum heated by means of a current to an arbitrarily defined temperature. In the case of many of these sources of light the members of the committee have made extensive measurements of their own, both to verify existing statements and to investigate questions yet unsettled.

The report of the sub-committee describes and illustrates at considerable length the bolometer—an instrument for detecting fluctuations of light—which was used in testing the standards of light named above, as well as several others, and gives a large number of curves and tables showing the results of numerous experiments. The conclusions drawn from these data by the committee are as follows:

It is evident from the summary of previous photometric researches and from the report of the work of this committee, that of all standards thus far used, candles are the least reliable. It is also evident from the bolometric curves that naked flames are subject to sudden and rapidly recurring fluctuations that may be almost entirely eliminated by the use of a properly constructed chimney.

It seems likely that many of the difficulties which are unavoidable with flame standards may be overcome by the adoption of a standard consisting of some surface electrically heated to a standard temperature.

The definition of the degree of incandescence of such a surface appears at the present to present almost insuperable difficulties, but the committee is at work upon a method for the measurement of the temperature of incandescent carbon, which may lead to results looking towards a solution of the problem.

It also has in progress experiments looking to the production of a light standard in which not only the burning material but also the atmosphere shall be of known and definite chemical composition. Liebenthal's experiments indicate clearly that this is a necessary condition to the production of any invariable flame. In the preliminary experiments now under way, a flame of a mixture of two parts acetylene to one part hydrogen, burns in a current of pure oxygen, all the gases being dry. The flame produced by these means is of dazzling brilliancy, its color being comparable to that of the lime light. No accurate measurements of its steadiness or reproducibility have yet been made.

This experiment will include a spectro-photometric study as well as an investigation of the range of fluctuation to which it is subject under different conditions of combustion.

[1]Preliminary report of the Sub-Committee of the American Institute of Electrical Engineers. Presented May 20, 1896.—Abstract.

AN ANALYSIS OF TRANSFORMER CURVES.[1]

BY CHARLES J. HUGUET.

THIS paper describes a number of experiments in regard to the distortion of primary current curves on open secondary. This was one of the most noteworthy features of Professor Ryan's paper on "Transformers," read before the Institute, and Professr Ryan ascribed this distortion to hysteresis. The same opinion seems to have been held by Fleming, Steinmetz, and every other writer since that time, with the single exception of Professor Rowland.

Dr. Sumpner had previously shown that, assuming hysteresis absent, a variation in the value of the permeability will superpose on the sinoidal magnetizing current a system of higher harmonics, causing it to become a symmetrically peaked curve. Professor Rowland, however, went further, and declared that the presence of the distorting harmonics is due, not to hysteresis, but to change in permeability, the effect of hysteresis being capable of representation as a simple resistance. However, he simply expressed this theory mathematically, without giving any experimental verification, and it is doubtless for this reason that the results of this paper have not been accepted in their entirety. This apparent conflict of opinion seemed to warrant further investigation, and it was the object of experiments conducted by the writer at Tulane University in June, 1895, to throw light on this question by analyzing the current curve into its various components.

The method employed in the measurement of the instanta-

[1]Read before the American Institute of Electrical Engineers, New York, May 20, 1896.—Abstract.

neous values was essentially similar to the telephone method described by Professor Nichols in his "Laboratory Manual," a galvanometer being substituted for the telephone. Runs were made at different voltages and rates of alternations from which the data were sufficient to discriminate the eddy from the hysteresis losses. By dividing the watts lost by eddies by the electromotive force applied the effective current due to eddies is obtained, and the ratio of this to the aforesaid electromotive force is the conductance due to eddies.

If the instantaneous values of electromotive force be multiplied by this conductance, and the resulting eddy current curve be subtracted from the original current curve the remainder will be the hysteresis curve; i. e., the curve that would be derived from the hysteresis loop. If in the same way we determine the conductance due to both eddies and hysteresis; i. e., if we represent the hysteretic loss as one due to a simple constant resistance, and subtract the effective current curve thus determined from the original current, the remainder will be a true wattless current, since the curve subtracted itself accounts for the watts lost. The wattless remainder is very fairly symmetrical with respect to the flux curve and is of the peaked character to be expected with permeability variable and hysteresis absent. A similar treatment of Professor Ryan's curve yielded a wattless remainder of similar character. These results seemed to verify Professor Rowland's theory, at least approximately.

But equally strong proof is afforded by several curves in the paper of Steinmetz—"On the Laws of Hysteresis" (Part III.).

The writer concludes that for sinoidal electromotive force:

(1) Hysteresis may in all respects be replaced by a constant resistance if the hysteretic characteristic be the quadrant of an ellipse.

(2) This condition is approximately satisfied for moderate ranges of magnetization (such as are used in practice), in reasonably good iron, and the higher harmonics are negligible. There will usually be a particular range that will give a nearly perfect approximation. On contraction of the range, the hysteretic current becomes more pointed than the sine, and on expansion beyond the critical range more flattened than the sine.

(3) The increased distortion of the hysteretic current for higher ranges will cause an increase in the higher harmonics, but the rapid diminution in the permeability on approaching saturation will cause a much greater increase in these harmonics, so that even at higher ranges the distorting influence of hysteresis is comparatively slight.

As a final conclusion, then, we may say that Professor Rowland's hypothesis that the higher harmonics in the transformer for sinoidal electromotive forces are due, not to hysteresis, but to variation in permeability, and that the effect of hysteresis may be represented by a constant resistance, is approximately correct, for reasonably good iron, is very nearly correct for the moderate ranges used in practice, and may, under certain conditions, be absolutely correct.

PARALLELING ALTERNATING STATIONS FOUR MILES APART.

A NOVEL method of central station working with alternating current apparatus has recently been installed by Mr. N. T. Wilcox, for the Seneca Light and Power Company, of Seneca Falls, N. Y. The installation is especially interesting, as it is the first instance where two alternating current machines, located in stations widely distant from one another, have been operated in multiple under the conditions incident to everyday central station practice.

Two 100 kilowatt, composite wound, 60 cycle, 2,300 volt General Electric generators have been installed, one being located about four miles from Seneca Falls, in the Waterloo station, which is operated by water-power only. Lights and power are furnished for general distribution at both ends of the line. The second generator is located in the Seneca Falls plant, where there is both steam and water-power. These two machines replace an Edison three-wire system in Waterloo, a 500 volt direct current motor system, and 1,000 volt single-phase alternating current system in Seneca Falls.

The incandescent lighting for both towns has been ordinarily operated from the Waterloo generator, the Seneca Falls dynamo being used only in emergencies or at such times as it was desirable to shut down the Waterloo plant. There being a large surplus of power at Waterloo the greater portion of the night, it is desirable to use this surplus for street lighting, but in case of low water it is necessary to have the arc dynamos in Seneca Falls, where there is steam power for emergencies of this kind. Consequently it is desirable to transmit this surplus water-power to be used on the main shaft of the Seneca Falls plant.

This problem is admirably solved by synchronizing the generators and throwing them in multiple, working both lights and power over the three No. 6 B. & S. wires which connect the Seneca Falls and Waterloo plants, nearly four miles apart. The Waterloo wheels are then run at full gate, transmitting their full power to the generator.

The regulating is done at the Seneca Falls end of the line. The surplus power not required for incandescent lights supplies energy to operate the Seneca Falls machine as a synchronous motor, the latter transmitting the power to the line shaft. As the lighting load falls off, the energy so saved is utilized in driving the shaft, until the amount delivered to the shaft entirely relieves the engine of its load, after which the steam power is cut off. By carrying a strong field on the Seneca Falls machine, all drop of potential due to line induction is entirely eliminated.

The working of the system has been most satisfactory, and especially so as the load is nearly all a lighting service, and the potential at both ends of the line is under perfect control. The increased economy of operation of the plants is quite noticeable, as it is now possible to utilize the maximum water-power during the whole evening.

EFFECT OF TEMPERATURE ON INSULATING MATERIALS.[1]

BY GEO. F. SEVER, A. MONELL, AND C. L. PERRY.

OF the many kinds of insulation, a few of the most common were chosen, i. e., paper, cloth, oiled paper and oiled cloth, and the following conclusions have been drawn from the result of 102 tests on samples of materials, which were kindly furnished by several of the most prominent manufacturers of electrical machinery.

The Apparatus.—The heating apparatus consisted of a glass cylinder 8 inches in diameter and 10 inches high, covered at the top and bottom with asbestos plates. The lower part of this cylinder was occupied by twelve enamel resistance tubes, 5 inches long and 24 ohms each. The terminals of these were

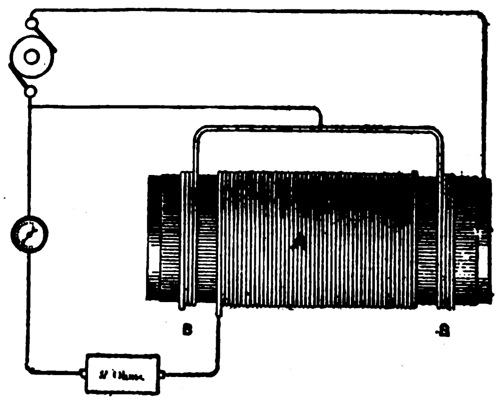

Fig. 1.

brought out through the asbestos plate. The current in these tubes being controlled by rheostat, the temperature in the cylinder could be varied at pleasure. An inch above the heating tubes, and supported by an asbestos collar, was a metal plate having holes punched in it to allow the free circulation of air in the cylinder. This plate was connected to one side of a galvanometer.

The insulating material to be tested was wrapped on brass cylinders ¾ inch in diameter and 3 inches long, the insulation not reaching quite to the end of the tube. The insulation was then wound with No. 26 B. & S. bare copper wire for a space of 2½ inches.

A Thomson high resistance galvanometer, a megohm box and a difference of potential of 500 volts were used in the tests. The thermometer used was of the nitrogen-filled mercurial type and capable of measuring from 0° to 400° C. When troubled with surface leakage, it was eliminated in the following simple manner. The diagram shows the connections while testing a tube and also the leakage shunt.

It will be seen from the diagram, Fig. 1, that all of the current going through the galvanometer must pass from the dynamo to the brass cylinder, and thence through the insulation to coil and on through the galvanometer. Any current tend-

[1] Read before the A. I. E. E., May 20, 1896.—Abstract.

ing to leak over the surface of the insulation from the brass cylinder to coil will be intercepted and shunted past the galvanometer by coils B B.

Plain Paper.—In this class forty specimens were tested. After the resistance at the temperature of the air (22° C.) was carefully noted, the temperature was gradually increased (100° in one-half hour) and readings taken every 10° up to 80° and from there on every 20°. Fig. 2 shows a curve which is characteristic of practically all kinds of plain paper.

It should be noticed, however, that in general the resistance

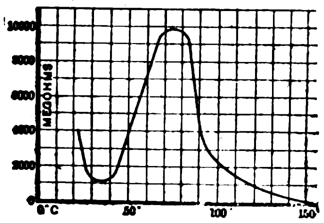

FIG. 2.—PLAIN RED PAPER, .009 IN. THICK.

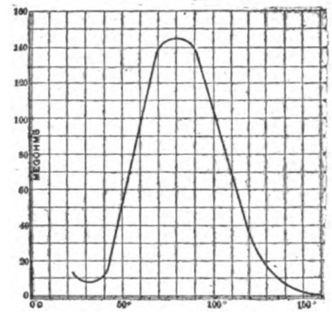

FIG. 4.—PLAIN COTTON DUCK, .015 IN. THICK.

of papers that are not protected from moisture falls between 22° and 50° and then rises rapidly until at 75° it has attained a maximum resistance. It should also be noted that this temperature of 75° is very constant for all kinds of paper. From 75° upward the resistance falls rapidly and at 150° is but a small fraction of its initial resistance.

The initial resistance of paper protected from moisture by japan (Fig. 3) is very high, but falls rapidly with the increase of temperature, as is the case with all material protected from moisture. (See oiled paper and oiled cloth.) Hence we see that all paper having a porous structure and therefore containing more moisture, has a lower initial resistance than the protected paper, but is affected by heat much less than the latter. This would lead to the conclusion that there are two phenomena taking place. First, the driving off of the moisture, which tends to increase the resistance, and secondly, some change (not a mechanical deterioration), in the material, dependent on the temperature and which may be called the temperature co-efficient. This temperature co-efficient tends to lower the resistance with increase of temperature.

Examining the several curves shown, we see that the initial resistance of unprotected papers is low on account of the presence of moisture. Now, on gradually increasing the temperature, the resistance falls during the first 20° or 30°, because the effect of the temperature co-efficient predominates during this period and before the material is warm enough to start the evaporation of the moistrue it contains. This, however, lasts but a short time, as the result of the evaporation is to increase the resistance very rapidly, until at 75° the temperature co-efficient again asserts itself and the resistance rapidly falls.

In the case of japanned papers (Fig. 3) the initial resistance is very high, due to the absence of moisture, but on being heated the resistance drops rapidly as the small quantity of water contained is evaporated off so slowly that it has very little counteracting effect on the temperature co-efficient.

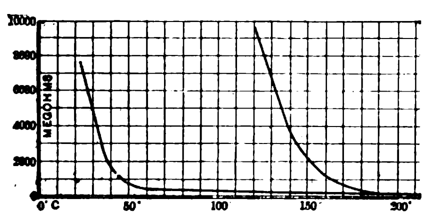

FIG. 3.—JAPANNED RED PAPER, .01 IN. THICK.

Paper does not seem to deteriorate mechanically at less than 180°; above this point the material begins to carbonize. At 230° a peculiar phenomenon takes place. The material after possessing a very low resistance from 175° upward, would at about 230° suddenly increase greatly in resistance and immediately after break down. This may be caused by some molecular rearrangement taking place at that temperature which changes the resistance of the material. Other cases wherein the resistance of a body changes at a certain temperature are well known, such as the recalescence of iron.

It would seem that paper insulation has a critical temperature somewhat analogous to that of iron, steel and nickel, but, of course, the characteristics of the materials are too different for any close similarity.

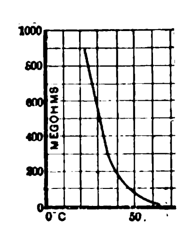
Plain Cloth.—Under this head twenty specimens were tested, including canvas, linen and muslin, of different thicknesses. The action of this material (Fig. 4) is much the same as that of paper (Fig. 2). The initial resistance is lower, as it contains more moisture than is the case with paper; for the same reason when the moisture evaporates off, the increase over the initial resistance is greater than with paper. By reference to the curves of paper and cloth it will be noticed that their resistance varies in the same manner. For cloth, as for paper, the maximum resistance is at 75° C. The material does not begin to carbonize until at a temperature of 180° C., and even beyond that point it loses its mechanical strength very slowly until past 220°. The explanation for the resistance of cloth varying as it does is exactly similar to that for paper.

Oiled Paper.—In this class fourteen tests were made, on papers of different thicknesses. With the single exception of one specimen (the resistance of which was very high) the initial resistance was lower than in the case of paper. (Compare Figs. 2 and 5.)

On increasing the temperature the resistance fell rapidly, the curve being much the same as that for japanned paper. The reason for the sudden decrease in resistance is the same as that for japanned paper. Oiled paper deteriorates mechanically at a lower temperature than paper or cloth, commencing to blacken at so low a temperature as 120° C.

Oiled Cloth.—In this class twenty-eight specimens of oiled silk, muslin, and linen of various thicknesses were tested. The initial resistance of this material is much lower than that of paper, and on increasing the temperature the resistance falls rapidly, the shape of the curve (Fig. 6) corresponding to those of japanned and oiled paper. The reason for the sudden decrease in resistance is undoubtedly the same as for the japanned and oiled paper. The insulation begins to char at about 120° C.

General Conclusions.—In the foregoing discussion there are



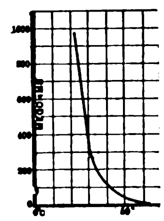


FIG. 5.—OILED PAPER, .0045 IN. THICK.
FIG. 6.—OILED SILK, .007 IN. THICK.

some main points to which it is necessary to draw attention. These are:

(a) That paper is a better insulation and withstands increase in temperature much better than cloth (shellac and varnish were not used in any of the experiments), oiled paper or oiled cloth.

(b) That paper and cloth have a maximum resistance when first heated at about 75° C. and are not injured mechanically under 180° C.

(c) That the point of maximum resistance for paper and cloth (in this case 75° C.) depends on the rapidity with which the temperature is increased. The authors suggest that if the material were kept at a constant temperature until all the moisture had been evaporated, the resistance of the material would then be its true resistance at that temperature.

(d) That all give a high resistance after cooling, but have little mechanical strength.

Oiled paper and oiled cloth, however, after having been heated to 220° C. and allowed to cool, not only have a high resistance, but became so firmly fixed to the brass cylinders that it was found necessary to remove them with a file.

(e) That it would be well to bake paper and cloth insulation to 140° C. before applying varnish or shellac.

(f) Referring to Fig. 3, it will be seen that on decreasing the temperature the resistance increased, but the second curve does not by any means coincide with the first. On further experimenting in this direction, it was found that there is no temperature at which the curve with falling temperature coincides with the first. This may be due to more moisture being driven out at higher temperatures which is not absorbed by cooling.

Here it may be well to mention an interesting phenomenon

that occurred in connection with this investigation. When the temperature has risen above 100° C., the zinc in the brass cylinder begins to leave its surface and combine with the copper wire wrapped about the insulation, so that the wire has a brass surface and the brass cylinder a copper surface.

VACUUM TUBE LIGHTING BEFORE THE A. I. E. E.—TEST OF MOORE VACUUM TUBES.

THE principal topic of discussion at the meeting of the American Institute of Electrical Engineers last week was the paper on "Vacuum Tube Lighting," read by Mr. D. McFarlan Moore, at the previous monthly meeting of the Institute.

Full scope was given to the members, and as a result elaborate discussion ensued, in which Mr. Steinmetz, Dr. Nichols, Professor Anthony, Mr. Hering, Mr. Kennelly, and a number of others participated.

The views expressed seemed to differ considerably, but there seemed to be a general consensus of opinion that a statement of the power consumed in Mr. Moore's tubes was what was wanted at this time. This information was supplied by Mr. Joseph Wetzler, who gave the following results of a series of tests made by him on May 18 in the booth of Mr. Moore at the exposition. These tests were taken by placing a Weston direct current milliammeter in the circuit of the Moore inductance coil, and reading the potential across the main leads to which the inductance coil was connected by means of a Weston alternating and direct current voltmeter.

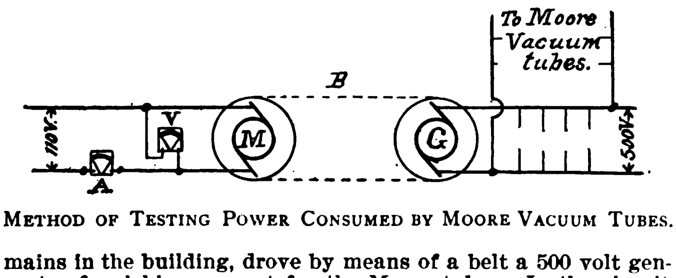
	500	*88	44.0

* With momentary rise to 120.

Professor Anthony, as well as others, expressed doubts as to the accuracy of the results obtained, owing to the peculiar nature of the current measured and suggested that a more reliable method would be to measure the energy consumed not by the generator supplying the current for the Moore vacuum lamps, but to measure the energy consumed by the motor which drives the Moore generator at the exposition.

In the evening the suggestion made by Professor Anthony was carried out in a test made by Prof. Anthony, Dr. E. L. Nichols, Mr. N. W. Perry, and Mr. W. W. Ker, on the tubes in the Moore exhibit.

The arrangement adopted is illustrated in the accompanying diagram. The motor, M, taking current at 110 volts from the



METHOD OF TESTING POWER CONSUMED BY MOORE VACUUM TUBES.

mains in the building, drove by means of a belt a 500 volt generator furnishing current for the Moore tubes. In the circuit of the motor was placed the ammeter, A, and across the terminals of the leads the voltmeter, V. The report of these tests as made to Mr. Moore by Professor W. A. Anthony is as follows:

"A Weston ammeter was placed in the circuit leading to the motor used for driving the generator which furnished the current for the vacuum tubes, and a Weston voltmeter was placed across the motor terminals. These instruments were read at frequent intervals, while one of us in the booth below noted the time of turning on and off the light. Comparing notes we found that when the tubes were all off, the motor consumed 12.5 to 13 amperes at 110 volts as a constant load. When the tubes were all on, the motor consumed 22 amperes at 108.5 volts. The motor therefore consumed, when tubes were not running, 1,402 watts; when the tubes were all running, 2,837 watts; due to tubes, 985 watts.

"There were in operation fourteen tubes, 7½ feet long, 1¾ inches diameter, one tube somewhat shorter, but 2½ inches in diameter, and a few tubes of special designs.

"We estimated that the whole was an equivalent of sixteen of the 1¾-inch tubes. This gives 61.6 watts per tube applied to the motor terminals. Assuming that 80 per cent. of this energy was delivered to the tubes from the generator terminals, the power consumed by each tube is 49.28 watts.

"This is practically the result obtained by Mr. Wetzler, by direct measurement of the energy consumed by the tubes, and disposes of the question raised by the writer as to the reliance to be placed upon the indications of a Weston ammeter in circuit with a vibrating interrupter.

"The only question now is as to the intensity of the light obtained. Of this it was impossible, under the conditions, to make any reliable estimate. Our results simply show that the light of the vacuum tubes as exhibited in your booth at the exposition is obtained at the expense of a little more than one horse-power.

"The instruments used in making these measurements were kindly loaned for the purpose by Mr. Pionnie, in charge of the Weston Electrical Instrument Company's exhibit, who gave us his assistance in making the necessary connections and in taking readings."

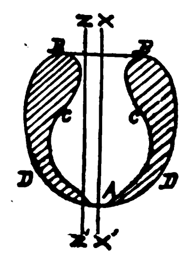
SUGGESTIONS FOR X-RAY EXPERIMENTS.

BY PAUL A. N. WINAND.

NOTWITHSTANDING the fact that a great number of investigators have lately operated with X-rays, it seems that one experiment has thus far been overlooked.

The most puzzling feature about these X-rays is that their course cannot be deviated from straight lines. In consequence, reasonings similar to those which enabled one to draw conclusions as to the nature of ordinary light, from the now classical experiments, cannot be as yet attempted for the X-rays. It has been found that X-rays will produce the discharge of a charged surface on which they impinge, and it would seem natural that this action should be attended by a reaction of the charged surface upon the X-rays. It would be interesting to investigate and determine whether such a reaction takes place or not, and if it does, it would afford a starting point for drawing conclusions as to the nature of the rays.

The charged surface may cause either a deflection or a



A SUGGESTED X-RAY EXPERIMENT.

reflection on the rays, or both; it may do so even without changing their course by polarization or by changing the phase, and this would be detected by interferences.

The first thing to try might be to interpose a hollow sphere, charged to a high potential, in the path of the X-rays. A thin rubber ball, aluminum plated, would absorb very little of the rays when not charged. If a deflection occurs, hollow prisms with rounded edges could be used. Two parallel surfaces would probably act like a plate of glass on light when the two surfaces were charged at the same potential—different from that of the surroundings—but they would act in quite another manner when the surfaces are charged oppositely, forming a condenser.

In order to submit the rays to the action of a single surface one might use a body shaped as is shown in the figure. A is a very small aperture; B, a much larger one. The body might be formed by the rotation of the loop A D B C about X X' as an axis, and the outer surface, A D B might be highly charged, while the inner surface would have but a slight electric tension. The ray, Z Z', would therefore pass through only one

highly charged surface, while the ray, X X', would not traverse any such surface.

A highly charged insulating substance would probably show an increased absorption, or a dispersion of the rays, even if the effect with one or two surfaces is not sufficiently marked to be detected. It would also be interesting to know if, and in what manner, the rays would be influenced when they are passed through a conductor traversed by a strong electric current. A conductor of aluminum will carry a very large current if energetically cooled by the circulation of a liquid. By using a liquid of very low temperature the current could be further increased on account of the increase of conductivity of the metal both for electricity and for heat.

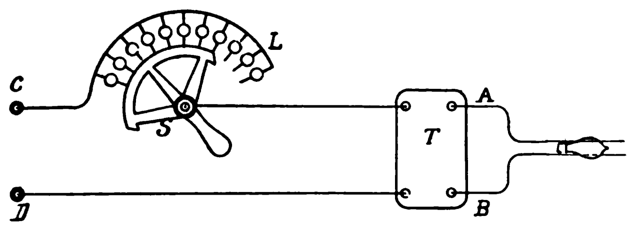
As I have not an opportunity to make such experiments myself, I write these short notes with the hope that some one more fortunate than I will find a way of determining what takes place under these conditions, and that he may draw interesting conclusions therefrom.

NEW METHOD OF CURRENT SUPPLY FOR CROOKES TUBES AND FOR TESTING INCANDESCENT LAMPS FOR VACUUM.

BY C. M. GREEN.

I AM now using some apparatus for lighting vacuum tubes and testing the vacuum in incandescent lamps which two months ago I considered impossible to operate, namely, an alternating current of less than 2,000 volts in connection with an ordinary transformer. The apparatus is in the hands of many central station men, especially those who have an alternating current system of lighting.

All the apparatus necessary is a few incandescent lamps, an ordinary commercial type of transformer and a supply of the secondary alternating current. I have been using Thomson-Houston oil transformers, type F, wound for 2,000 volts primary and 50 or 100 volts secondary. One of 300 watts capacity is of sufficient size for this purpose. The object of the bank of lamps is to be able to vary the voltage at will by turning them on or off. The accompanying diagram shows the manner in which the apparatus is disposed.



GREEN'S METHOD OF TESTING FOR VACUUM IN INCANDESCENT LAMPS.

To the transformer, T, the leads, A and B, are connected at the primary terminals, or rather the fine wire terminals which are used in this case as the secondary side. To the other side, which is the heavy wire winding the current, supply is connected, first passing through a bank of lamps, L, as shown, by means of the switch, S.
which is the heavy wire winding, the current supply is connected to the tube, and for testing incandescent lamps, rods connected to the same terminals are held at each side of the lamp bulb. The writer has also found this apparatus very useful for testing insulating joints or couplings for combination fixtures and electroliers.

ON A ROTATIONAL MOTION OF THE CATHODE DISC IN THE CROOKES TUBE.[1]

BY FRANCIS E. NIPHER.

IT is well known that the equations which represent the properties of the magnetic field external to a conductor, are inconsistent when applied to points within the body of the conductor. Maxwell disposes of this absurdity to which the equations lead, in the single sentence which closes section 606 of his "Electricity and Magnetism." He says: "Within the substance of the conductor, there is no such thing as magnetic potential."

It has long seemed to me that this failure of the equations must be the result of leaving some elements of the problem out of the discussion. I have spent a great amount of time in seeking for some rotational phenomenon hitherto unrepresented in the equation. Until recently the results were wholly negative. While recently experimenting with a Crookes tube I observed that the circular aluminum disc of the cathode became slightly loose on the aluminum wire, and that it was constantly rocking in rotary motion on the wire. After several days of use, during which it had been decided to construct a tube with discs capable of rotation, the cathode disc suddenly became loosened, and began to rotate slowly on the wire as an axis.

The bearings were somewhat rough, and the disc was not perfectly balanced. It often stopped, but then began to rock against the obstacle until it again freed itself. The direction of rotation was contrary to the hands of a clock, when the disc was viewed from the point where the cathode wire pierces the wall of the tube. All attempts to accelerate or retard the motion by means of strong bar magnets, as in Barlow's wheel, were without effect. Placing the tube at various distances from the induction coil and giving the disc all possible positions in the earth's field, produced no change in the rotation. A more decided rotation was produced by using the brush discharge of a 24-inch Holtz machine. No rotation has been produced as yet when the leading wires were in metallic contact with the conductors of the Holtz machine, but when the leads consisted of rods having spherical terminals, separated by short spark intervals, the rotation was always seen. When the loose disc was made the anode, no tendency to rotation has been observed. Thus far all attempts to produce the effect in air of ordinary pressure have failed, but the work in this direction is not yet concluded.

In the tube used, the tendency to rotation was not observed until by long use the vacuum had become very high, and it has now nearly reached the limit where the sparks pass around the tube, rather than through it.

The leading-in wires are at right angles to each other in the tube used. Tubes are now in preparation which will have rotary discs facing each other as well as at right angles to each other, and various other features, by which it is hoped that many questions which at once suggest themselves may be answered. There is much reason to suspect that the gas particles do not shoot off normally from the surface of the disc, but in a vortex, the axis of which is in the two dark spots opposite the cathode faces. The fact that the anode does not respond, and that similar experiments in open air have thus far failed seems to point to the cathode discharge as the direct active agent. This view is not easily reconciled with the result of the experiment made by Crookes with the hemicylindrical cathode ("Nature," July 3, 1879, p. 229, Fig. 3), but the figure shown does not seem to quite agree with the description of it. Experiments are now in preparation which will decide this question. It is possible that the rotation observed is a direct action and reaction between the current in the disc, and the external field due to the current. In this case the rotation apparently ought to be producible in open air, and on the anode terminal of the Crookes tube.

Whatever may be the direct agency producing this rotation, it seems apparent that we now have an experimental basis for imposing a term representing a rotation into the equations representing the conditions within a conductor.

THE STANDARDIZATION OF LAMP SOCKETS.[1]

BY ALFRED SWAN.

THE topic which I introduce deals with the vexed question of lamp sockets. Its object is to promote an interchange of opinion on the part of those present who are interested in the subject, and by its discussion before this convention give to the question that status which its importance demands.

This question of the standardization of the lamp socket was recently raised by The Electrical Engineer, and various letters appeared in that journal on the subject. A notable feature of that correspondence was the preference, almost unanimously declared, for a particular type of socket because of the comparative cheapness of its lamp base.

The fact that a socket outlives many lamps does, undoubtedly, as things now are, encourage the use of that particular type of socket which is useable with the least expensive form of lamp base, though the socket in question may not in itself be the best or the cheapest. This fact would seem clearly to indicate that, preliminary to the standardization of the lamp socket must be the standardization of the lamp base. When scientific fitness, due simplicity and point of lowest cost shall have been attained in regard to the lamp base, then will, necessarily, result a standard socket.

[1]Remarks addressed to the N. E. L. A. May 5-7, 1896.

Following, therefore, this line of argument and concerning ourselves first with the lamp base, let us, with due reference to its functions, consider what we should demand in a standard lamp base.

The elements involved in this question are threefold—electrical, mechanical and economical. Good insulating conditions are of the first importance, to guard against leakage, or other abnormal action, in the wires connecting with the lamp. Mechanical considerations concern the means by which the base is attached to the lamp—as well as the means by which, when so attached, it couples with the socket. The method of coupling with the latter, while insuring a rigid and unfailing contact, should be such as not to put an undue strain upon the lamp. Cheapness is, of course, a sine qua non.

The death rate in lamps, as compared with sockets, being high, and the base, as a rule, not surviving the lamp, obviously the less value we involve in that base the better. How many of the present types of lamp base conform to these standard requirements? What could well be more inappropriate to the delicate structure and graceful form of the lamp itself than is even the best—or rather, let us say, the least objectionable—of those appendages with which lamps are now encumbered.

In addition to their offending in this respect they are objectionable in that they involve the use of plaster, which we know is bad, electrically considered. Their large size renders them heavy and clumsy; sockets are, therefore, similarly clumsy; and, to sum up, all are needlessly expensive, the cheapest costing not less than $6 a thousand, while, I am fully warranted when I assert that one-third of this sum might, and eventually will, provide a suitable and appropriate fitting.

Manifestly, therefore, a standard lamp base must be the first point for determination—a standard not merely accepted as such, but one that by virtue of its essential merits shall be fairly and fully entitled to such recognition—a standard that shall accomplish the nearest approach to finality possible in that direction.

Having accomplished that, the rest necessarily follows; a lamp base involves a socket to suit it.

Having got the best and cheapest lamp base that is possible, no other, in time would be used, and hence, as a corollary, we arrive at our standard socket.

I am not unaware of the revolutionary character which, in some of its aspects, this movement may appear to assume, nor do I fail to appreciate the practical difficulties which necessarily confront any and every attempt to cope with this standardization question. But, I submit, where the need for amendment is so palpable and the call for that amendment so imperative, as in this case it is, difficulties must needs be met and overcome. This is not a question for solution by mere process of elimination or survival—in which case it might be left to work its own cure; it is in my opinon a matter involving radical change and a new departure.

In view of the fact that high tension lamps are in all probability going to be the rule in the future, the question of a safe socket acquires enhanced importance. Porcelain will, no doubt, come largely into use for that purpose, and this will greatly modify the conditions now governing the lamp base, and will make possible that simplification and economical change in this regard which I have already indicated; and, as even a small saving on the cost of a base becomes a considerable item in the aggregate, it is in this direction, therefore, that economy and improvement should be most encouraged.

In this connection I might mention that the idea lately occurred to me—and I since find that others have put forward the same idea—to engineer this matter economically by means of a detachable form of base—a form of base, that is to say, admitting of repeated and continuous use, thus saving expense on renewals.

I have come to the conclusion, however, that that idea, though apparently all right in theory, would not operate satisfactorily when reduced to commercial practice—for, even were this re-use made possible by returns on the part of customers —and this is very doubtful—the allowance necessary to induce those returns, added to shipment and other charges, would go far to neutralize any saving there might otherwise be.

Regarded from the commercial standpoint, therefore, I come to the conclusion that the most practical and satisfactory solution of the matter is a form of the base, or mount, so inexpensive that when the lamp is destroyed the base may be allowed to go with it, as in itself a thing of no value. And it is to this form of base that I allude in the foregoing, and to which I shall, later, more particularly refer. In practice all lamps would, in such case, be fitted at the time of their manufacture with this inexpensive mount and would so be stored, complete and ready for shipment at a moment's notice, the manufacturer, the supplier and the consumer all participating in the advantages that would certainly attend this simplified order of things. The commercial benefit that would undoubtedly follow in the train of this standardization of the lamp alone makes that end worth striving after, for, that the present complicated and vexatious state of things operates to retard the progress of electric lighting, and is therefore detrimental to its industrial interests, cannot be denied.

But the purpose of these remarks is not, at this moment, the advocacy of any specific form of base or socket. That will follow. Their object, as stated at the outset, is to take the sense of this representative gathering, first upon the main question at issue —that is, the question as to the desirability of a standard socket—and next, should that question be affirmatively met, to determine, if possible, a line of action that shall best conduce to the desired end.

But, in conclusion, I would urge that any resolution on this question at which this convention may arrive, shall not lose sight of the fact that a standard base is the kernel of this matter; not merely a base chosen as a standard from one of the prevailing types, but a base which is yet to be evolved—one that shall in all respects fulfill standard requirements and so give us as its complement our standard socket.

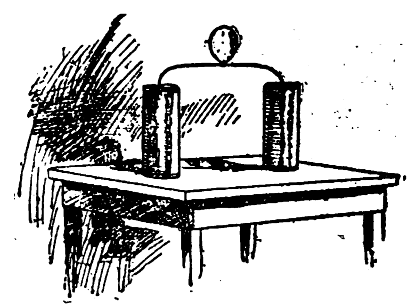
THE TESLA VACUUM LAMP.

DURING the past week Mr. Tesla has announced in various interviews with the reporters of the daily press that he has effected improvements in the methods of vacuum tube illumination announced by him in 1891. Speaking to a New York "World" reporter, Mr. Tesla is quoted as follows:

"There has been little change in the apparatus I now use compared with that I displayed at St. Louis. The basic principles are the same. I have simply made improvements and marked advances. I have found the causes of loss of energy and have largely overcome them. Already I can deliver 10 per cent. of the initial energy in a pure white light. This is three times the efficiency of an ordinary incandescent lamp."

The New York "Herald" of May 24 gives the following description and illustration of Mr. Tesla's improved lamp:

"It is a very simple looking contrivance. Two brass cylinders, looking for all the world like the empty shells of shot for a rapid fire cannon, stand about six inches apart. A light



THE TESLA VACUUM LAMP.

wire extends between the two, which probably contain coils, but about them Mr. Tesla will not say a word. Directly in the center of this thin wire is an ordinary electric light bulb used for incandescent lighting. The little point usually at the bottom of the bulb points upward. There is no filament in the vacuum. It appears merely as an ordinary bulb would appear if the carbon filament had been destroyed, but the interior has been exhausted of air many times more than the incandescent light bulb. When the current is turned into the electrodes and so into the bulb there is no foreign substance to burn. The electric molecules have the vacuum all to themselves. They move at the rate of from 3,000,000 to 4,000,000 vibrations a second. No one point gets bright and then seems to ignite the rest, as in the bulb usually seen. There comes a glow, just as there is a glow in the eastern sky at dawn, and then it becomes rapidly intenser, until the whole interior of the bulb sends out light, just as though a piece had been cut out of the edge of the sun and packed into the little glass receptacle."

According to the account in the "Herald" this lamp, with the same cubic contents as a 16 candle-power incandescent lamp is of 250 candle-power capacity.

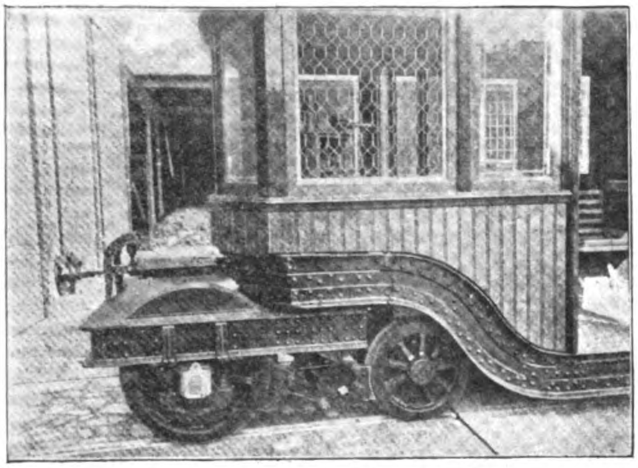
PROF. R. O. HEINRICH, formerly of Lehigh University, and of late years with the Weston Electrical Instrument Company, has gone to Europe to take up his permanent residence in Berlin as the representative of that company, for whose admirable apparatus the demand in England and on the Continent has grown to very large proportions. Prof. Heinrich during his long residence in America has won a host of friends and admirers who wish him all manner of success and prosperity.

ELECTRIC TRANSPORTATION.

THE BUDA-PESTH UNDERGROUND RAILWAY.

A NEW underground line has been constructed under the residential streets of Buda-Pesth. The whole track had to be done on the cut and cover system, and its cost was over 1,000,000 florins per kilometre. The line is double track throughout, and will be opened for traffic, it is believed, next month. The stations are only 400 metres apart, and it is intended to run the cars at a maximum speed of 40 kilometres an hour. A novel system of speed regulation has been adopted, the object of which is to do away with the necessity for any intelligence on the part of the motorman. The motorman can only cut the motors in and out, but cannot regulate their speed, this being done automatically. A solenoid is connected to the brush terminals of the motor on the car, and as the counter electromotive force increases, so does the magnetism of the solenoid. The device is extremely ingenious, and it can be regulated in such a way as to practically fix the distance in which the car will attain its maximum speed. Electric brakes are also used, similar to the Sperry brake.

There are two motors on each car, they also being used for braking by short-circuiting them, and making them work as



TRUCK AND CAR FRAME OF BUDA PESTH UNDERGROUND ELECTRIC RAILWAY CAR.

generators. The height of the tunnel from the top of the rail is 2.85 metres; the tunnel could not be made any higher, as otherwise it would have been lower than the level of the Danube, and that would have increased the expense of construction enormously. The cars have been specially built; each car is mounted on two bogies, shown in the illustration taken from the "Electrical Review," London, and inside they are exceedingly handsome, and look more like the saloon of a yacht than a tram car. There are 29 seats, and there is room for 15 to stand up. The total weight of a car when empty is 12 tons. One 50 horse-power motor is mounted on each truck.

The line was built and equipped by Messrs. Siemens & Halske, of Berlin. The current is taken from an overhead conductor, which is fixed to the roof of the tunnel by means of cast iron shoes. The tunnels and the stations are all lined with glazed tiles. The line was constructed with the object of connecting the system of tramways which encircles Buda-Pesth with the center of the city. Tramways were not possible, as the town authorities would not allow any rails to be laid down along the streets of the residential quarters through which this line would have had to pass.

COMBINED NAPHTHA AND ELECTRIC LAUNCH.

"Forest and Stream" says: Commodore Rouse, Seawanhaka Corinthian Y. C., will this season test a novel combination of naphtha and electricity on the flagship Iroquois. The yacht's naphtha launch, one of the regular boats built by the Gas Engine and Power Company, will be fitted with a special dynamo that can readily be shipped aboard and connected to the engine. When the launch is not in use during the day, and lying at the boat boom, the dynamo will be put aboard and connected and the engine started up, the wheel revolving in the water. The electric current will be used to charge the storage batteries aboard the yacht which supply the electric lights with which she is fitted throughout. When not in use the dynamo will be stowed below on the yacht. How the arrangement will work in practice is yet to be proved.

CAN ELECTRICITY SUPPLANT THE STEAM LOCOMOTIVE ON TRUNK RAILWAYS?—XIII.

(*Concluded.*)

Wm. Baxter, Jr.

COST OF ELECTRICAL EQUIPMENT FOR THE PENNSYLVANIA RAILROAD SYSTEM.

POWER REQUIRED.—In order to etsimate the cost of an electric equipment for the Pennsylvania Railroad it will be necessary to determine the amount of power required. This we can do by several different processes, and from the results thus obtained, by making proper allowances for the probability of error in each case, can arrive at a figure that will probably not be very far from what we would obtain if possessed of data more directly applicable to the case.

We can obtain from Tables 7 and 8 the total number of miles run per year by all trains, and by reducing this to the hourly traffic and multiplying by the power required per train, as already worked out in a previous paragraph, can deduce a figure for the total power necessary to operate the road. We can obtain another result by taking the yearly movement of freight and passengers and reducing it to an hourly basis with the proper allowance for weight of cars. The data for such a calculation are also contained in Tables 7 and 8.

Another estimate can be made by taking the number of locomotives and multiplying by the average power developed by each, making, of course, a proper allowance for engines not in use. Finally, we can take the coal consumption and determine the power from this by assuming a certain consumption per horse-power hour. Taking the first case we would have:

Miles run per hour by passenger trains	2,982
Miles run per hour by freight trains	4,080
Miles run per hour by switching trains	2,059
Miles run per hour by construction trains, etc.	191

These figures are based upon the assumption that the miles run on Sundays are much less than on week days, and also that the movement of trains is not uniform, but that at some hours of the day it is much heavier than at others. The daily average has been taken as equal to the yearly run divided by 330, and the hourly mileage as equal to the daily divided by 15.

We can get the number of trains in motion at any time from these figures by dividing the hourly total run in miles by 30 for passenger trains, and by 15 for freight and all other trains. We would then have the following as the number of trains in motion:

Passenger trains	99.4
All other trains	422

Assuming the average power required to move passenger trains to be 350 horse-power and for freight trains 250 horse-power, we would have for the total power required:

	Horse-power.
To move passenger trains	34,790
To move all other trains	105,500
Total	140,290

Calculating the power by the number of trains (see Tables 7 and 8), which is a short way of obtaining the second estimate, we would have, by changing from a yearly to an hourly basis, in the same way as in the preceding case:

Passenger trains, per hour	77.9
Freight trains, per hour	94.2

As the average number of miles run by passenger trains is about thirty-four and by freight trains forty-five miles, as obtained by dividing the train-miles by the number of trains, it follows that each passenger train is in motion for 1.13 hours, and each freight train for three hours, from which we would get:

Passenger trains in motion at one time	$77.9 \times 1.13 = 88$
Freight trains in motion at one time	$94.2 \times 3 = 282.6$
Other trains in motion at one time	141.3

The switching trains have been assumed to be equal to 50 per cent. of the freight, as the mileage of the two is in about that proportion.

Estimating the power per train as before for freight and

passenger service we would have the following results, which are but slightly different from the first:

	Horse-power.
Power for passenger trains	30,800
Power for all other trains	105,975
Total	136,775

Estimating by the number of locomotives we will get the following: Number of passenger engines in use, 80 per cent. of the whole number, equal to 382. Average miles per year, 39,000; which, at the average speed of thirty miles per hour, equals 1,300 hours in motion per year, or, 3.93 hours per day. Therefore, the total hours of service per day of the 382 locomotives amount to 1,404 hours, which, divided by 15, gives 93.56 as the average number of passenger engines in use at one time.

Taking the freight engines, we have 827. The average miles per year, 23,100; divided by the speed, 15 miles, equals 1,540 hours per year, or 4.66 hours per day; 827 × 4.66 divided by 15 gives 256 freight engines in use at a time. In the same way we get for switching engines 151.4 as the number in use.

From this calculation we have the following number of locomotives in use at a time:

Passenger	93.56
Freight	256
Switching, etc.	151.4

Figuring the power as in the previous calculations, we have:

	Horse-power.
For passenger trains	32,746
For all others	101,850
Total	134,596

Estimating the power by the coal consumption we will get (by basing the calculation on the amount used by each class of engines, as determined in previous calculations, and taking the coal consumed per horse-power at 4.6 and 10 pounds, respectively, for passenger, freight and switching engines), the following results:

	Horse-power.
Power for passenger service	48,450
Power for freight service	78,833
Power for switching service	20,290
Total	147,573

Of these four estimates the last is the largest, and is also the one that in all probability is the most accurate, although not necessarily so. If the efficiency of locomotives is as high as we have assumed it to be, then this estimate cannot be very far out of the way; but the fact that the estimate is higher than any of the others, instead of showing that the figures are not as reliable, may in reality show that the coal consumption of locomotives is not as low as we have assumed it to be.

The figures obtained above represent the average power of the average day during the hours when traffic is the heaviest, but there are seasons in the year when the traffic is largely increased, and hours of the day when the demand for power is considerably more than has been allowed for. To meet these unusual demands we should increase the power about 25 per cent. to allow for the increased traffic at certain seasons of the year, and again another 25 per cent. to meet the heaviest demand during the day at such times. Making these allowances we will have.

	147,573	horse-power.
+ 25%	36,894	
	184,467	
+ 25%	46,118	

Grand total, 230,585 horse-power

This is the amount of power that would have to be delivered on the track, and if we assume the efficiency between the steam engine shaft in the power station and the car axle at 60 per cent. we would require about 385,000 horse-power steam engine capacity in the power stations.

As there are 2,656 miles of road, the average power per mile would be about 145 horse-power. As there are about 350 trains in motion at a time, without counting switching trains, the average distance between trains would be 7.58 miles. As the average power required for each train is about 300 horse-power, it follows that the capacity of stations would have to be small unless they were located at long distances from each other. But the requirements of the road would not be properly met with stations of small capacity, because, although the average power of a locomotive is not very great, some of the express engines may draw on the source of energy for a thousand, or even more, horse-power. It, therefore, is evident that whether the points from which distribution is made are close together or far apart, there must be considerable reserve capacity. This indicates at once that the higher economy of installation demands that the stations be placed as far apart as practicable.

By making use of rotary transformers each station can be made to supply forty-five miles of road without an undue expenditure of copper. Dividing the road up into sections of this length, the total number of stations required to operate the entire system would be sixty. The average number of trains drawing energy from a station would be less than six.

In each station current at, say, 700 volts would be generated to feed the trolley circuits for a distance of seven and one-half miles each way; other currents of, say, 5,000 volts would be transmitted to rotary transformers located fifteen miles from the station in both directions. These rotary transformers would generate a current of 700 volts that would pass directly to the trolley circuit. Each transformer would supply fifteen miles of trolley line, and the station proper another fifteen miles, making in all forty-five miles of road that would be operated from each station.

In this arrangement two-thirds of the current energy would be transmitted fifteen miles under an electromotive force of 5,000 volts; it would then be converted into a current of 700 volts and transmitted an average distance of three and three-fourths miles. The remaining third of the energy would be distributed under an electromotive force of 700 volts at an average distance of three and three-fourths miles.

The capacity of each station would be 385,000 ÷ 60 = 6,500 horse-power.

	Horse-power.
Maximum working capacity	8,000
Average output	4,000

The following figures give the cost of each station, with its two sub-stations and the trolley lines and feeders for forty-five miles of road. The capacity of lines is calculated to give an efficiency of conversion of 60 per cent., with an output of 4,000 horse-power on the assumption that the generators will give an efficiency of 92 per cent., and the rotary transformers 85 per cent., working at this capacity. As the average number of trains per section is less than six, and as the average power required for each train is about 300 horse-power, or 500 at the station, the actual average output should not be over 3,000 horse-power; therefore, the amount of copper allowed in the following estimate will be sufficient to render a 60 per cent. efficiency certain under all ordinary conditions of working.

COST OF TROLLEY LINES AND FEEDERS.

Trolley	$40,000
Feeders	160,000
Material, other than wire, and cost of constructing trolley lines	135,000
Cost of construction and material for feeder lines	60,000
Total	$395,000

COST OF STATION.

Steam plant	$100,000
Electric plant	85,000
Building	15,000
Total	$200,000

COST OF SUB-STATIONS.

Converters	$30,000
Buildings, $1,000 each	2,000
Total	$32,000

From the above we have:

Cost of line	$395,000
Cost of station	200,000
Cost of sub-stations	32,000
Grand total	$627,000

The total cost of sixty stations, or the cost of equipment for the entire line, would be $37,620,000. To this must be added the cost of motors. These should not exceed $6,000 per motor car. As to the number that would be required to take the place of 1,800 locomotives now used, there may be room for difference of opinion. The advocates of steam may claim that it would require as many motor cars as there are locomotives, but inasmuch as the mileage of the latter is only about one-third that of what we know could be obtained from the former, we would be justified in saying that 600 motor cars would be enough, and such would be the case if the schedule of trains could be so arranged as to keep the motors running the greater portion of the time; but, probably, this could not be done. Therefore, we will take a medium course and assume

that 1,000 would be required. We would then have for the cost of motors $6,000,000, and for total electric equipment of Pennsylvania Railroad system $43,620,000.

This estimate is only a rough approximation; anything more in detail or more accurate could not be given unless we had full information as to amount of traffic over each mile of road, location of curves, grades, etc. Even were such data available, the labor involved in working out a complete estimate, covering every detail, would be such as to preclude the undertaking.

Although the figures we have obtained above are only approximate, they are undoubtedly much nearer to the actual cost than a mere good guess, and enable us to form some idea of what the transformation of a large trunk line railway system from steam to electricity would involve in the way of expenditures; and by the aid of investigation of the cost of operation previously made, we can see whether the saving would justify the outlay. In order to complete the data that will enable us to draw conclusions, we will give an estimate of the cost of operating the power stations and maintaining the line. The cost of coal and the repairs to motors were included in the investigation of the saving in expenses of operating the road; therefore, all we have to consider here is the cost of labor and repairs to line and station machinery.

Cost of operating one station and forty-five miles of trolley and feeder lines:

Chief engineer, per year	$2,000
First assistant engineer	1,800
Second assistant engineers (2)	3,000
Firemen (10)	5,000
Helpers (4)	2,000
Linemen (12)	7,200
Oil, etc.	1,000
Total for wages, etc.	$22,000
Total for wages for sixty stations	$1,320,000
Repairs on $37,620,000 at 4 per cent	1,404,800
Grand total	$2,724,800

As the allowance for repairs is only 4 per cent., it may be considered by some as very low; but experience shows that on some of the apparatus even this rate is too high. The repairs on large engines are less than 4 per cent. per year, and on generators are not much over 2 per cent. On boilers they are over 4 per cent., and as to the repairs on the line it must be remembered that the wages of linemen should properly be charged to this item. Considering these facts it must be conceded that 4 per cent. on the entire cost of stations and line is over rather than under the actual cost.

Going back now to the estimate of the saving in operating expenses, we find that the figures were $7,606,442.24. Deducting from this the cost of wages and repairs on stations and line as just obtained—which is $2,724,800—we have as the net saving $4,881,642.24, and as the total cost of the electrical equipment would be $43,620,000, this saving would amount to more than 11 per cent. on the investment.

As already stated, economy of operation is not the only claim of superiority that can be made for electricity. We have also shown that it can be made safer, and that much higher speeds can be obtained, because the power that can be developed by an electric motor is practically unlimited, while that of a locomotive is not. The comfort of the traveling public would be increased, because the cars would be surrounded by pure air, while trains drawn by locomotives, especially when running at high speeds, are enveloped in an atmosphere largely composed of the products of combustion.

If the claims herein made are well founded, electricity would prove cheaper and safer, would increase the comfort of passengers, and render more rapid transit possible. Such being the case, why should it not supersede steam? If railroad managers were convinced that these claims are true, a transformation of their lines would at once be undertaken; but they are not convinced, and will not be until they learn the facts in their own way, and that way will be by going slowly, and trying a branch road here and another there, until they have obtained a sufficient amount of data from actual experience to dispel all doubt. When that point is reached the transformation will be rapid, and the complete invasion of the steam railway field will take place at a pace equal, if not greater, than that of the street railways. Already, the New York, New Haven and Hartford, and the Pennsylvania Railroad, are feeling their way by experimenting on branch roads with light equipments. This work will no doubt be followed up by the equipment of more important branches with heavier rolling stock, until a sufficient amount of practical data is obtained to justify a change of entire systems. This same course will in all probability be followed by other railroads, and if so, electricity may gain a strong foothold on trunk line railways much sooner than its most sanguine friends expect.

LETTERS TO THE EDITOR.

EFFICIENCY OF THE JACQUES CARBON CONSUMING PRIMARY BATTERY.

IN the description of the "Jacques Carbon Consuming Primary Battery" given in The Electrical Engineer of May 13, some very interesting facts are stated. There are doubtless other facts concerning this battery that would have been interesting if stated; for example, the amount of carbon consumed outside of the pots. That carbon is "consumed" in this battery, particularly in the furnace part, there can be no doubt. But that the apparatus is a primary battery is not quite so certain.

The statement is made that to maintain a current of 16 amperes at 90 volts in a series of 100 cells for 18¾ hours required the "consumption in the pots of about 8 pounds of carbon." The most important part of the carbon, that consumed outside of the pots, is not stated. It is probably safe to say at a guess that the amount consumed outside of the pots is at least many times as great as the amount consumed in the pots. Why the efficiency of 82 per cent. should be calculated on the small amount of carbon consumed in the pots, while the comparatively great amount consumed outside is ignored, does not seem very clear. If there is any evidence to prove, or reason to believe, that the electrical energy came from the carbon consumed in the pots, and not from that consumed in the furnace, a statement of that evidence would also be interesting.

It seems to me, from the data given and the description of the apparatus, that, instead of being a primary or galvanic battery, it is purely a thermo-electric battery; that the consumption of carbon in the pots, instead of being the source of electrical energy, was a result caused by the thermo-electric current, which originated in the heat of the furnace, that is, in the carbon consumed outside of the pots.

My reasons for this belief are the following:

1. The iron pot and carbon rod joined by the fused sodic hydrate constitutes a very powerful thermo-electric cell. (Vide Jenkin's "Electricity and Magnetism.")

2. The thermo-electric current of this cell must necessarily pass through the electrolyte connecting the carbon and iron, and cause oxidation by electrolytic action.

3. The current obtained by Dr. Jacques, 30,000 ampere hours, is electro-chemically equivalent to 7.5 pounds of carbon. But it was obtained from eight pounds of carbon "consumed in the pots." Hence, if the energy came from this carbon by galvanic oxidation the current efficiency was $\frac{7.5}{8}$ = 94 per cent., which seems rather high.

C. J. REED.

AFTERGLOW IN LAMP FILAMENTS.

I have an ordinary 16 candle-power, 52 volt lamp, which to me is a curiosity. It burns with its usual current and voltage in the ordinary manner, but as soon as the current is shut off by means of the key socket, the lamp, when grasped firmly in the hand, gives out from its filament a soft blue light of a phosphorescent appearance. Having had several years' experience in incandescent work, and in handling lamps of various makes, and, never having seen anything of this kind before, I am anxious to know the cause of the phenomenon.

Hoping that you or some of your readers may take the trouble to explain this to me, I am,

O. C. R.

Woburn, Mass.

STANDARDIZING INCANDESCENT LAMP SOCKETS.

My attention having been drawn to a letter under the above heading, from Mr. F. R. Upton, in the "Western Electrician," I am led to reply because of what I conceive are the inconsequential conclusions of that letter.

This question has been raised, and is being debated, not in the interest of standardization merely, but to the end also, and not less, that the right thing be standardized.

Because a certain style of lamp base happens to be more largely employed than any other, to argue that, therefore, that style should receive permanent indorsement is wholly to miss the purpose and object of this movement; for, even were the base here referred to the best of any now in vogue—which is a question—it cannot for a moment be contended that it is the best possible, or that it fulfills the requirements of a standard.

In the consideration of this question, with a view to its settlement upon a permanent basis, the extent of which any of the present types have been, or are being, used, is a matter of trivial importance in comparison with the object of having, in the end, the right thing.

ALFRED SWAN.

CONTENTS.

VACUUM TUBE LIGHTING.

NOT since the days when the Edison incandescent lamp was first announced as a practical commercial illuminant has the public, both electrical and lay, been stirred as it has during the last few weeks by the practical demonstration which Mr. Moore has been giving of his method of vacuum lighting at the Electrical Exposition. The daily press from one end of the country to the other has taken up the subject and aroused an interest which cannot but be of benefit in the long run to the industry at large. But, perhaps, the most important development within the week has been the establishment of the accuracy of the figures of the power expended in the Moore tubes, which had been called in question in various quarters. It will be recalled that in the demonstration which Mr. Moore gave before the American Institute of Electrical Engineers the twenty-seven tubes employed by him on that occasion, as announced in The Electrical Engineer, required little more power than an equal number of 16 candle-power incandescent lamps. Through the unfortunate manipulation of the motor furnishing power to operate the apparatus, the impression was gained by many present that the 7½ horse-power motor employed was laboring under great difficulties to carry the load imposed upon it, and in spite of the figures published in The Electrical Engineer there were many who still remained skeptical. In the discussion which took place before the American Institute of Electrical Engineers last week an opportunity was afforded for an expression of opinion and the lack of any information on the subject of power consumption in Mr. Moore's paper constituted the principal argument of several of the speakers. This criticism, it cannot be denied, was a just one, but the results of actual tests made on Mr. Moore's apparatus by one of the editors of this journal, and which are given in another column, showed that Mr. Moore's original figures were quite conservative. Even these tests were criticised on the score that the instruments employed may not have been adapted to the peculiar nature of the current with which Mr. Moore operates. The doubt here expressed must also be conceded to have been a proper one, and Prof. Anthony's suggestion that the energy consumed by the tubes be estimated by the power developed on the motor side of the combination was an eminently timely one. It is a matter for congratulation that its author followed up the suggestion by an actual test in the manner proposed by him. The results of that test, which we print on another page, demonstrate amply that the figures given by Mr. Moore, and by the editor of this journal, were well within bounds, and, indeed, if they erred at all, did so on the side of safety. The test of Prof. Anthony and Dr. Nichols and their associates show that the Moore vacuum tubes each consume a fraction over forty-nine watts, and this on the assumption that the efficiency of the motor and dynamo combination was 80 per cent., which is certainly high for the size of the motor and dynamo employed.

We cannot but express our gratification at the fact that all further criticism on the lines above referred to must now be set at rest. We have little doubt that Mr. Moore will be able, with further experiments, to show even far better economy of power than any he has thus far shown. This opinion seems justified on the observed fact that some of the tubes tested as

low as 30 watts, and also on the evident fact that the energy actually contributing to the illumination of the tube must be but a small fraction of that absorbed by the coils whose reactive effect serves to produce the electrical disturbances in the tubes. That the results obtained by Mr. Moore have given a marked impetus to vacuum tube lighting, is evident by the fact that Mr. Tesla, after five years of neglect, has taken up the subject, and claims to have made considerable advances over the results obtained by him when he first electrified the scientific world with his brilliant high frequency experiments. We use the word neglect in reference to Mr. Tesla advisedly, for we have far too high an opinion of his genius to believe that even a small portion of that time devoted by him to vacuum tube work would not have resulted in a substantial advance at his hands. Even Mr. Edison, who seemed to have cut adrift from electricity during the past few years, has, we understand, also taken up the subject, and promises to show a vacuum lamp before the close of the Electrical Exposition. This lamp, we understand, will embody a phosphorescent material as the principal light-giving factor. All these facts combine to show that the time cannot be far distant when vacuum tube lighting will enter upon its career of commercial usefulness. Mr. Moore has undoubtedly set the pace, and pushed the vacuum tube lamp forward an enormous step toward its commercial utilization.

While the efforts at devising a practical vacuum tube lamp are thus being pushed with vigor, we cannot but express our regrets at the unseemly controversies, not to say bickerings, into which rival inventors in this field have allowed themselves to be drawn in the daily press. The public, it is true, is a party in interest to all advances in the arts, but surely nothing can be gained by airing before the world at large petty jealousies and criticism not backed up by facts. On the contrary, such proceedings can only serve to cast discredit on all alike. We may be permitted to suggest that in this case as in similar advances, it is works, and not words, that count.

SYSTEMS, SPECIALIZATION AND STANDARDS.

SUCH a fine and remarkably varied collection of apparatus as that now on view at the National Electrical Exposition invites to many reflections, and suggests many thoughts. Some of the lessons of the show we have already ventured to point out during the past few weeks, and now, as the exposition draws to a close, it may not be inappropriate to touch upon some further considerations. Chief among these is certainly the evidence that the show affords of the breaking down of the old "system" and the irresistible tendency toward specialization.

There was a time, and not so long ago, when all the developments of electric light and power were summed up in the word "system." If anybody brought new apparatus on the market, it had to be completely of that make from the first nut to the last binding post. A mere lamp or a mere dynamo counted for worse than nothing. You could either take the "system" or leave it, but your name was anathema and "mud" if you ventured to put one man's lamp on another man's machine; and all the terrors of the damned were in store for those who thus "infringed." The echoes of those barbaric old days are still in the public ear. We all of us still use the phraseology of that feudal period, and are still inclined, from force of habit, to look askance at a device built to be good solely of and for itself, as the sole end of its being, and appealing for patronage solely on merit. But the times have changed. The General Electric Company to-day, perhaps better or worse than any other concern, represents the exploded idea that you must not buy a single thing that the "parent" company does not make; and its gigantic failure on those lines of monopoly is apparent to all the world, for there is hardly a product, except some heavy stuff, in regard to which the General Electric Company is not frequently surpassed and often beaten clean out of its boots by the independent specializing manufacturer.

The local companies, the owners of isolated plants, and the municipalities, all recognize to-day the value of this specialization, and even this week the division of the big order from the city of Chicago indicates the positive trend of events. There was a period when the crudeness of the art rendered the "systems" a good thing, except that there was such an infinite variety of them; but now the "systems" have crumbled away in ruin, except in a few specific instances where the word applies legitimately to certain specific narrow lines of apparatus or method.

No one can deny that the art is not gaining immensely by this change from a grouping where the company that built locomotives also made watches—so to speak—to a separation by means of which a number of concerns have sprung up modestly capitalized, well equipped, and ably manned by talent exerting itself on the things best suited to respond in a perfect product. We may be wrong, but to our way of thinking the whole future and prosperity of electricity lies in the continuance of this process. Even in so recent and new a field as the utilization of electrical heat, specialization has begun. Obviously it will pay inventors to take up individual ideas and hammer them out into new arts. Electricity as a field of work now has an enormous stock of principles and ideas. What we all need are the arts that embody them.

And this brings us to the point that a need of the hour is standards. Take the one subject of light, and see what a variation there is in units, in measurements, in lamps and every other branch of the matter. Take even fan motors. Except that they have to run on predetermined voltages, which does enforce that much of uniformity, there is an utter welter of variation in every other respect. Now, with good standards, every article would be gauged by them and then more than ever merit and quality would tell. "Standards" are the very antithesis of "systems," as the latter word was once understood.

THE NIAGARA TRANSMISSION.

IT is a pity that a hasty piece of journalistic work should have been allowed to mar the general harmony and success of the exposition, and should have evoked the indignation that is naturally aroused when innocent persons are blankly accused of fraud. But while such is the case, retraction has been made, and we do not see how the libel suit brought by the Exposition Company can do any further good. Every journalist is liable to make mistakes, and when he apologizes promptly, that ought to be enough, unless there is proof of actual injury to reputation and purse.

We are not surprised that there have been doubters as to the actual delivery of energy from Niagara, but we are surprised that a thing so readily susceptible of proof should be attacked without any sort of rational investigation. Moreover, the standing of the companies and individuals interested ought to have been enough for their protection from such an imputation, involving incredible baseness on the part of every one concerned.

The transmission would, of course, have been vastly more important if it had taken place on regular power wires with power in large bulk. But such conditions were not obtainable, while the Western Union wires were. It is at least highly creditable to the ability of the designers of the Westinghouse Company that they produced right off, with only the change from a smooth to a grooved pulley, the apparatus to receive the power coming from Niagara. Some day the engineers will probably give us all the figures. Meantime, whether they deliver 50 watts or only 5, they have, as Mr. Stillwell modestly claims, done what they started out to do—made their motor run at the end of a 465-mile circuit. We understand that several interesting and novel conditions have been observed in the little experiment during the month.

AIR MOTORS FOR NEW YORK STREET CARS.

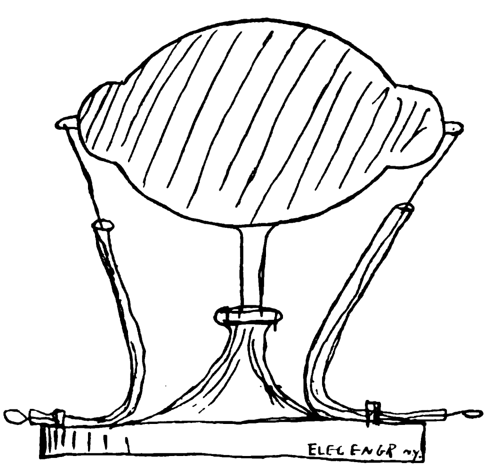
THAT the Metropolitan Traction Company should not be enamored of the underground trolley system put in for it on trial by the General Electric Company is not surprising, for as we have already intimated, from time to time, it has been found pretty expensive and troublesome to run the road. But it is surprising to find the company harking away after air motors for their cars. That is one of the old buzz saws that so many fingers have been clipped by, and now a new generation of engineers and capitalists is in line for ultimate painful amputation. It would have been better to stick to the G. E. underground system, imperfect as it may still be.

News and Notes.

THE EDISON FLUORESCING VACUUM LAMP.

CONSIDERABLE interest has been aroused during the past week by the announcement that Mr. Edison had devised a new type of vacuum lamp which he intended to show at the Electrical Exposition during the week. The exact nature of this lamp was described by Mr. Edison himself in The Electrical Engineer of April 15 and we need therefore only repeat Mr. Edison's own words to recall the matter to our readers:

"A vaccum tube, the inner portion of which has fused to it crystals of tungstate of calcium when exhausted to the X-ray stage, gives out scarcely any of the rays; on the other hand,



The Edison Fluorescing Vacuum Lamp.
(*From a sketch made by Mr. Edison.*)

the tubes shine with a splendid white fluorescence. We have here a true fluorescent lamp, possibly commercial, as a very small bulk gave in the photometer 2½ candle-power with an extremely small amount of energy. The white light is of a character not unpleasant, but quite the contrary. The spectroscope reveals the reason; the spectrum has strong red rays."

We understand that Mr. Edison has succeeded in largely increasing the efficiency of his new type of vacuum lamp. The latest form of the lamp, shown in the accompanying engraving, resembles very closely the X-ray tube adopted by Mr. Edison with the electrodes at opposite ends, but with a slightly greater diameter at the center.

A CUSTOMS DECISION ON LAMP SHADES.

The following decision has been handed down by the Board of United States General Appraisers: P. H. Petry & Co. vs. Collector at New York.—Covers for electric lights made of glass beads strung on wire. The claim that the same are dutiable at 10 per cent. under paragraph 99 was overruled, and the assessment at 35 per cent. under paragraph 102 was affirmed.

AN ELECTRIC LAUNCH, 36 feet long, has been put on the lake at Prospect Park, Brooklyn. It makes the round in 23 minutes under half headway.

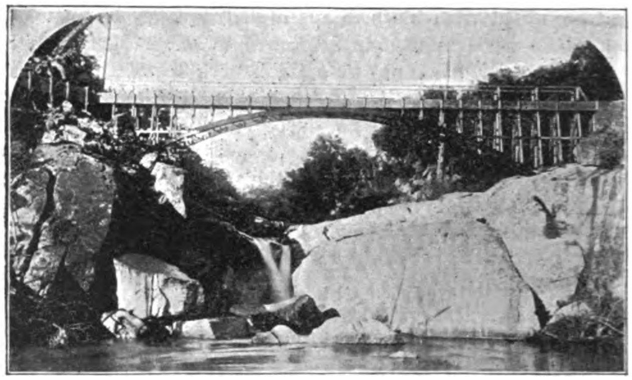
Power Transmission.

TRYING VOLTAGE EXPERIMENTS AT TELLURIDE.

The Westinghouse Company, in connection with the Telluride Power Transmission Company, of which L. L. Nunn is general manager, is carrying on some experiments in power transmission at high voltage. Mr. Nunn has been supplied with converters amounting in all to about 200 horse-power capacity, and suitable for transforming from 3,000 to any desired higher voltage up to 60,000 volts, and these converters are used as raising and lowering transformers in transmitting about 100 horse-power over an ordinary iron telephone wire a distance of about two and a half miles to operate a stamp mill, the iron wire constituting the line costing only $35. When Mr. Nunn first proposed this transmission of two and a half miles some years ago, using direct current transmission, the estimate made for copper was in the neighborhood of $65,000. This transmission plant has been run at various voltages from 15,000 to 60,000 volts inclusive, and during snowy weather at about 35,000 volts.

THE 35-MILE THREE-PHASE TRANSMISSION AT FRESNO, CAL.

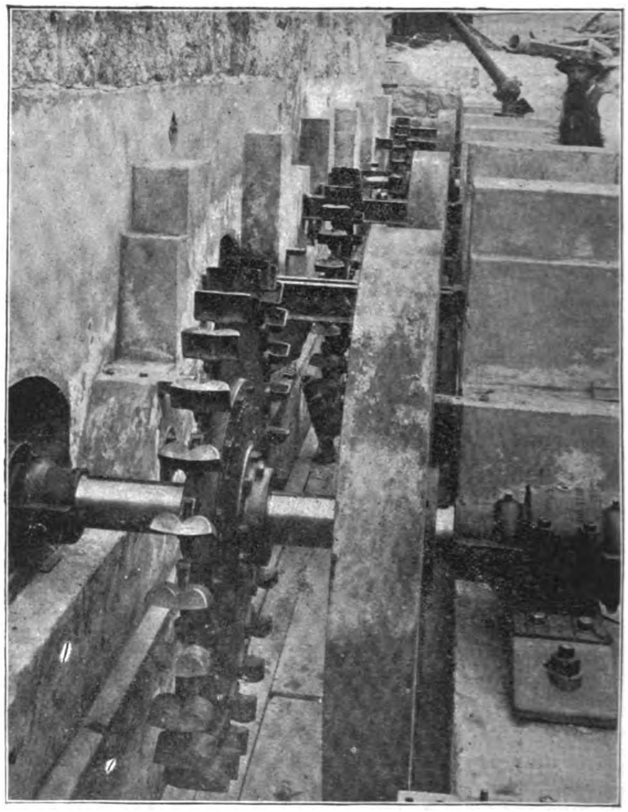
THE work on the three-phase electrical plant at Fresno, Cal., which has been carried on for the past year, is rapidly drawing to completion. This transmission will be the longest and most unique in many ways ever effected commercially, and will result in endowing Fresno and the surrounding towns and villages with a system of light and supply of cheap



Flume Bridge, Fresno Transmission Plant.

power equal to that of any Eastern city situated in proximity to a coal center.

The power house is located on the north fork of the San Joaquin River in Madera County, about thirty-five miles northeast of Fresno, at the foot of a steep hill and facing another equally as steep. The point of diversion lies some miles



Pelton Wheels, Fresno Transmission Plant.

away where the north fork runs through a narrow cañon with solid rock walls. A flume and ditch with a total length of seven miles have been built and excavated on the easy sidehill slopes and the right of way has been cleared of all trees and obstructions for a width of 150 feet. The grade of the canal and flume is 5.28 feet to the mile. The lower bank of

the canal is sufficiently wide to serve as a wagon road for the inspection teams. The minimum low water flow of the stream at the point of diversion is 50 cubic feet per second, which will develop, at the head available, over 7,000 horse-power at the water wheels.

The reservoir is situated at the top of a high hill, the river being some 1,600 feet below. The pipe line leading from the pressure box in the reservoir is 4,100 feet long, and in this distance the vertical difference in level is not less than 1,400 feet—one of the highest heads of water ever used for power purposes. For the first 400 feet the pipe is of riveted steel, and for the balance of the distance is lap welded, with lock joints, five-eighths of an inch thick at the lower end with a diameter of 22 inches.

At the power house the pipe enters a receiver of three-quarter inch steel, 57 feet long and 30 inches in diameter. The joints are of the butt strap type, and the receiver is designed to stand a working pressure of 300 pounds per square inch.

The power house, of native granite, is 75 feet long and 30 feet wide, with a wooden roof. The water wheels are outside the main power house, the shafts passing through the heavy granite wall, which effectually keeps all water and moisture out of the dynamo room. The three wheels are of Pelton make, 57 inches in diameter, each capable of developing 500 horse-power at 600 revolutions per minute under an effective head of 1,410 feet. They have steel plate centers and bronze buckets and are fitted with flywheels five feet in diamter. Separate wheels are provided for the exciters.

The electrical installation is not yet completed. It will consist of three General Electric three-phase generators each of 350 kilowatts capacity, directly connected to the water wheel shafts. The current will be raised in transformers to 12,000 volts and will be caried on poles for 34.4 miles to the substation at Fresno. It will then be transformed down to 200, 1,000 and 3,000 volts, the first for the low tension supply in the business portion of the city; the second for the three-phase supply in the residence districts; the third for the three-phase supply to the vineyards and wineries within a radius of ten miles from the sub-station.

Contiguous to the station is the pump house of the Fresno Water Company, in which the pumps are already operated by a 75 horse-power, three-phase induction motor. This is the first motor operated by the transmitted current. The work is being rapidly pushed forward and within a few weeks it will be finished, and another great step in the electrical transmission field will have been made.

MISCELLANEOUS.

THE HAYDEN CENTURY CLOCK.

BY M. H. LOCKWOOD.

MR. J. F. HAYDEN, class of '96, Trinity College, Durham, N. C., has designed and constructed a novel clock which may now be seen running in the Physical Laboratory.

The clock is run entirely by electromagnets which are actuated by the current from an earth battery.

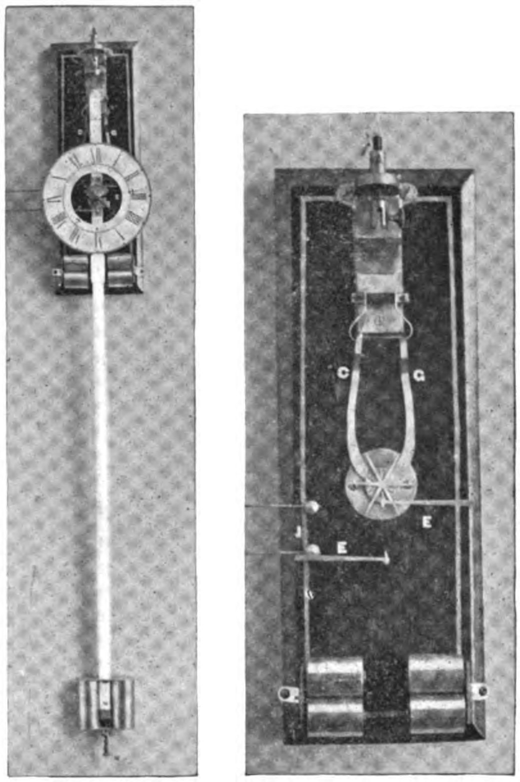
The pendulum is constructed after the usual pattern, with wooden shaft and heavy cylindrical weights for the bob, and is suspended from the bracket attached to the back-boards, as seen in Figs. 1 and 2. It is the pendulum that runs the clock.

By means of the automatic switch, C G, the current from the battery is sent around first one and then the other of the electromagnets D and H. The screw, A, at the upper end of the pendulum is electrically connected to the upper binding post, J, and also to two contact points, one on each side of the shaft at L. The arms, C and G, of the automatic switch are insulated from each other. The upper arm, G, is in metallic connection, through the central screw, with a wire in the rear of the back-boards, leading to the coils about the pair of magnets, H. The lower arm, C, rests on the brass plate, F, the latter being connected with the coils about the magnets, D.

As the pendulum swings, it is readily seen that the current will alternately pass around the two pairs of electromagnets, D and H, and the two soft-iron armatures at I will be alternately attracted.

The working of the clock can best be understood by following the current through a complete cycle. Starting from the upper of the binding posts, J, the current passes to A, then through the piece of sheet steel, B, attached to the upper end of the pendulum shaft, to the contact points, L. When the pendulum starts from the magnets H towards the magnets D, the contact is made from L through C, and the current will pass around magnets D, and from there to the lower binding post, completing the circuit through the battery. It will be seen that this aids the force of gravity in carrying the pendulum towards D. When the pendulum starts back from D, the contact is made with G, and the current passes around the magnets H, giving the pendulum a pull in that direction. If these pulls at each stroke of the pendulum are sufficient to overcome the loss by friction of the moving parts, it will continue to vibrate.

To regulate the amount of current passing to the electromagnets, two brass tips are affixed to the shaft at K, their distance apart being readily adjusted by screws. Shortly after the contact is made with C, as the pendulum swings toward D, the connection is broken by the arm, C, coming in contact with the strip, K, on that side, and if the current is very strong the strip will push the switch far enough to throw G into contact, and the current will pass around the magnets H. The latter acting will tend to retard the motion of the pendulum toward D. By adjusting the distance between these strips, almost any current may be used to run the clock.



THE HAYDEN CENTURY CLOCK.

As a novelty in the construction, the works and dial are placed upon the pendulum and swing with it. The seconds hand is attached to a ratchet wheel having sixty teeth, and is actuated at each stroke of the pendulum by the pawls, E E, which are attached to the back-board. The motion is communicated to the minute and hour hands by the usual intermediate wheels. The movement is jeweled and the pawls have steel tips. The tips of the pawls work in semicircular grooves in such a manner as to make it impossible for them to catch more than one tooth at each stroke of the pendulum. The length of pendulum is adjustable both at the upper and at the lower end by means of suitable screws.

The lower end of the pendulum is provided with two needle points fixed in the nut, n. These pass simultaneously through two drops of mercury, each of which is in metallic connection with one of the binding posts at the right hand lower side of the case. Thus we have a clock that may be used in many laboratory experiments where a seconds pendulum is required. A local circuit will be closed through an electric bell or telegraph sounder at each stroke of the pendulum. All the electrical contact points in the clock are of platinum, and the working parts of the switch are adjustable for wear.

The earth battery is built in the ground near the building and consists of several old boiler grate bars as one electrode and several bushels of coke as the other. The battery will last for an indefinite period and should run the clock for 50 or 100 years.

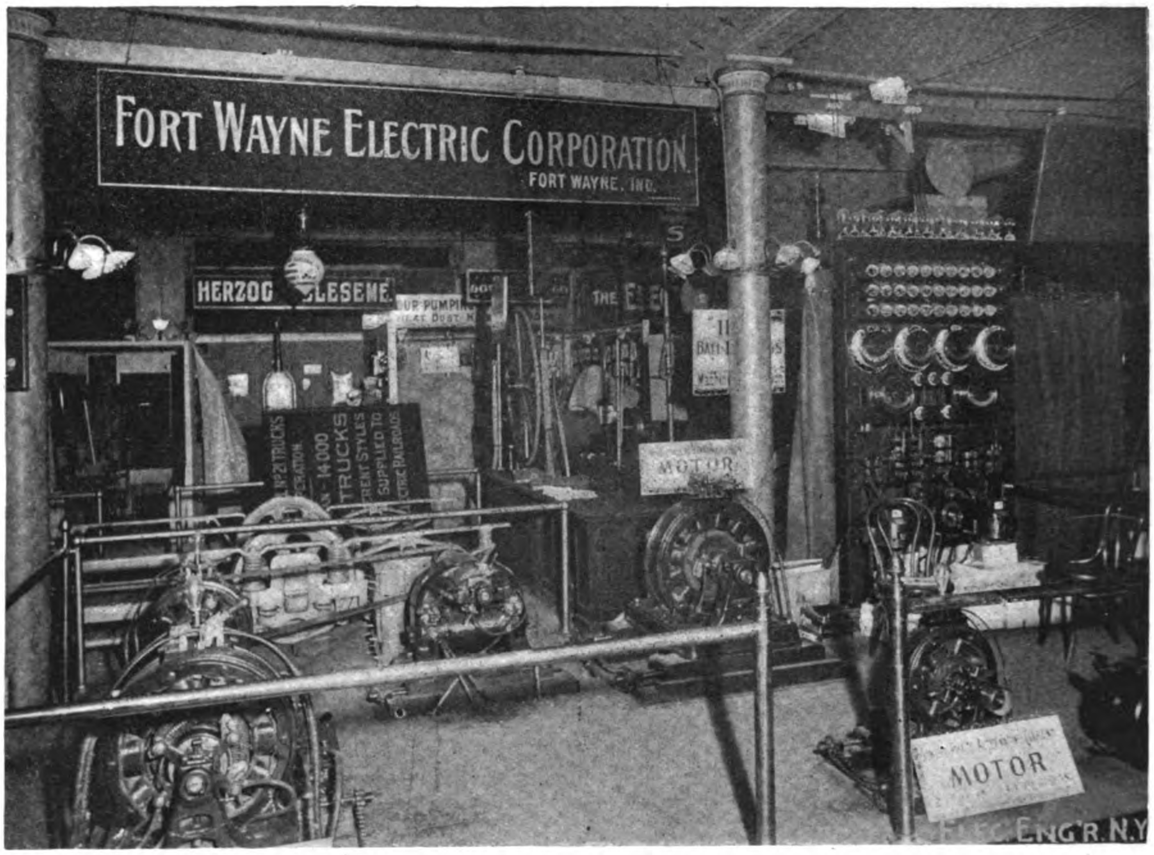


EXHIBIT OF THE FORT WAYNE ELECTRIC CORPORATION.

THE "ELECTRA" CARBON EXHIBIT OF HUGO REISINGER.

EXHIBITION NOTES—III.

PAGES FROM OUR EXPOSITION ALBUM.

LAST week we presented a number of views of leading exhibits at the National Electrical Exposition accompanied by notes upon them as well as upon many of the other exhibits of which our photographer had not, in spite of steady, hard work, succeeded in securing pictures at the time of our going to press. This week we are able to supplement our notes with a large number of fine views of exhibits previously described, but not hitherto illustrated. They will serve to give an excellent idea of the generally high quality of the exhibits and of the admirable decorative effects aimed at. It is said that no snow has ever been given in New York at which the effect or tout ensemble was better. This is the more striking when it is remembered that a large majority of exhibits embrace machinery of the most prosaic and practical character. Still, electricity is clean, neat and handy, and for this reason alone, if for no other, encourages the practitioner on such occasions to try his hand at decorative effects.

MARCUS NATHAN.

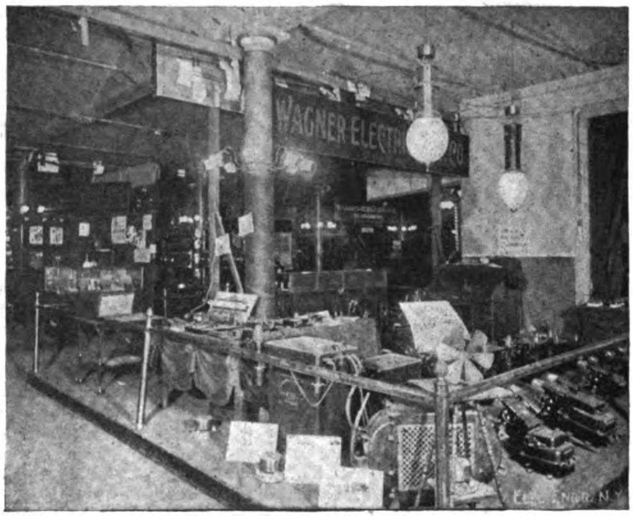
We give herewith the portrait of Mr. Marcus Nathan, the superintendent of the National Electrical Exposition, to whose valuable services we made incidental reference last week. Mr. Nathan is only thirty-one years of age, but is ripe with a long business experience. His earlier training lay in the dry goods field, and as manager of the house of Bloomingdale Bros. he made a high reputation for executive ability. He has now been connected with the Grand Central Palace for two years, in various ways. He has always had a taste for construction

SUPT. MARCUS NATHAN, OF NATIONAL ELECTRICAL EXPOSITION.

work, and for several years past has been engaged in electrical and machinery contracting work for the export trade to Cuba and Mexico. To this familiarity is due the ease with which he has grappled with many of the serious problems of wiring and lighting at the exposition. His work in general there has had all the qualities that go to make such a great enterprise a brilliant success.

THE EXHIBIT OF THE WAGNER MFG. CO.

WE have already referred to this company's exhibit, and now take much pleasure in illustrating it. Aside from the high excellence of the goods shown, the company deserve warm praise for their enterprise in thus making so bold a bid for Eastern patronage, a good many miles from their St. Louis home. But no one who has inspected the apparatus can



THE WAGNER ELECTRIC CO.'S EXHIBIT.

remain in doubt as to its ability to make friends and customers everywhere.

The exhibit of the company includes the most complete line of transformers in the building. The types and styles of these have already been illustrated in our pages, and the collection includes a large transformer for high potential long distance work. There are also arc lamps to show the application of the Wagner "Economy Coils," and a fine display of alternating and direct current fan motors of the well known and popular Wagner make. In addition to all this, there is shown a fine line of switches and tablet boards, in which the workmanship and ingenuity of design are admirable.

DE VEAU & CO.'S EXHIBIT.

SITUATED directly to the left of the main hall entrance of the exposition is the exhibit of Messrs. De Veau & Company, of New York. The heart of the telephonist is delighted by the variety of types of telephone instruments, receivers, transmitters, etc., which are shown mounted on the wall and exposed in the show case, as illustrated in our engraving

DEVEAU & CO.'S EXHIBIT.

representing the exhibit. The variety of transmitters for short and long distance work is specially noteworthy, showing that the company have provided for every contingency in the telephonic field. The telephone, switchboard and magneto bell out-

fits on exhibition show that the company are fully prepared to handle interior as well as exchange systems.

THE CURTIS-HULL AUTOMATIC ELECTRO FEED WATER PURIFIER AT THE EXPOSITION.

The Automatic Electro Feed Water Purifier, as shown by the cut, and its action, with personal explanations given by three of the Curtis-Hull Manufacturing Company's representatives at the Electrical Exposition in New York, space 257, ground floor, is creating much interest among the manufacturers, engineers, and others there in regard to preventing the formation of scale in steam boilers by galvanic action, produced automatically. The plates used in the purifier are specially prepared, according to the chemical analysis of the water used, and the heat of water must be 150 deg. or over, before passing through the purifier.

It is in no sense a filter, but by the electrical action that takes place, the affinity of the scaling ingredients for the iron, and also for each other, is destroyed, and the matter is deposited in the bottom of the boiler, like dust or otherwise, and then blown off.

If old scale has accumulated, and no new is allowed to form, it must dissolve and rot off from natural causes. A great saving is claimed in coal over all boiler purges, from the fact of its not allowing any scale to form. It also saves in cost of water rents when well water can be obtained. It also stops pitting and corrosion by using the ingredients that cause it for battery energy, and takes care of itself if attached and used as directed.

THE EXHIBIT OF THE GAMEWELL FIRE ALARM AND POLICE TELEGRAPH CO.

As noted in our columns last week, the above company, of New York City, have a very fine and extremely interesting exhibit at the National Electrical Exposition. It is also well handled and excellently described by the courteous attendants, who are constantly delivering terse, brief lectures to the large crowds that gather around the booth. Whenever a Gamewell box is opened on the aisle, a thick throng gathers at once; and here, where there is seen also the central apparatus for the fire house or police bureau, the fascinated public just stays around all the time. Such an exhibit must be regarded as a check on crime, for any one disposed to go and do wrong in the way of incendiarism and theft will certainly have deeply impressed on his mind the fact that detection and arrest are likely to come swiftly.

The space occupied is in Section J, 73-74, and is handsomely

THE GAMEWELL FIRE ALARM TELEGRAPH CO.'S EXHIBIT.

draped and fitted up. At each aisle corner of the exhibit, carrying a blue and gold banner, is a lamp post. One supports a Gamewell fire alarm box and the other a police signal box of the exact type used with such success in many large cities, and now so universal that in a little more than twenty-five years the company have equipped over 700 towns, cities, etc., with their fire and police telegraph systems. The boxes shown are connected in actual operation with a central station or exchange. At the wall on the back of the exhibit are grouped police boxes, the clock on the time stamp and dater for signals coming into central, the bank signal system, engine house indicator and gong, and different styles of fire boxes, keyless, etc. There is also the apparatus for the automatic Manhattan auxiliary alarm that throws a signal from any building where it is installed on the nearest fire box. Flanking this apparatus is the famous Gamewell automatic repeater for fire circuits, receiving on one and sending out over all the rest, and always placed as a central attraction in modern fire headquarters. On the other side is the big tower bell striker that is powerful enough to raise a whole town from slumber.

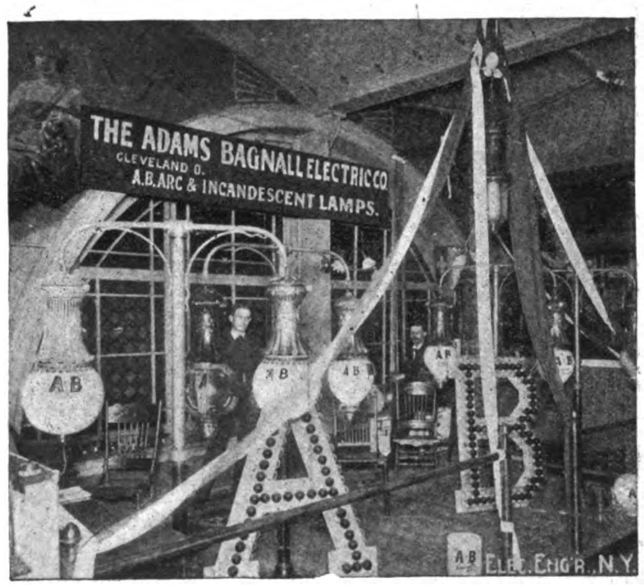
In the middle of the space against the back wall is a model and typical central office cabinet equipment with four circuits, each indicating for itself by a special drop, and having associated with it the dater and time stamp, as well as testing circuit, galvanometer, etc. It is a superb equipment and elicits much admiration. Here it is used more particularly to exemplify the instantaneous workings of the Gamewell police and bank signal systems as grouped around it on the back wall. The police box, for example, can send in seven signals by indicator alone, and then has the invaluable telephone service to fall back upon, each box having its receiver and transmitter. The bank signal box is equally efficient and easy to work, giving the maximum of instantaneous alarm and protection.

It is worth notice that the company build their apparatus with remarkable care and precision, and are now making their own time stamp for the cabinets, such stamps taking care of all chronological variations in the months and years. The woodwork is also beautifully finished. In regular work the company use a variety of batteries, including storage, dependent upon conditions. At the exhibit the apparatus is very successfully run by Gordon-Burnham cells.

This notice would not be complete without mention also of the fire alarm whistling machine, intended to act as a substitute or auxiliary for the gong. In short, ingenuity and enterprise are seen in every part of the exhibit, which is in charge of Messrs. A. L. Tinker and C. F. Waulen.

THE REMARKABLE EXHIBIT OF ADAMS-BAGNALL LAMPS.

The Adams-Bagnall Electric Company, of Cleveland, O., have one of the finest exhibits of arc lamps ever shown. They exhibit shunt and differential series arc lamps in various finishes, alternating, constant potential lamps for running two in series on 110 volt incandescent circuits, inclosed arc lamps which burn on incandescent circuits, from 100 to 150 hours from one pair of carbons, etc. A novelty in this type of lamp



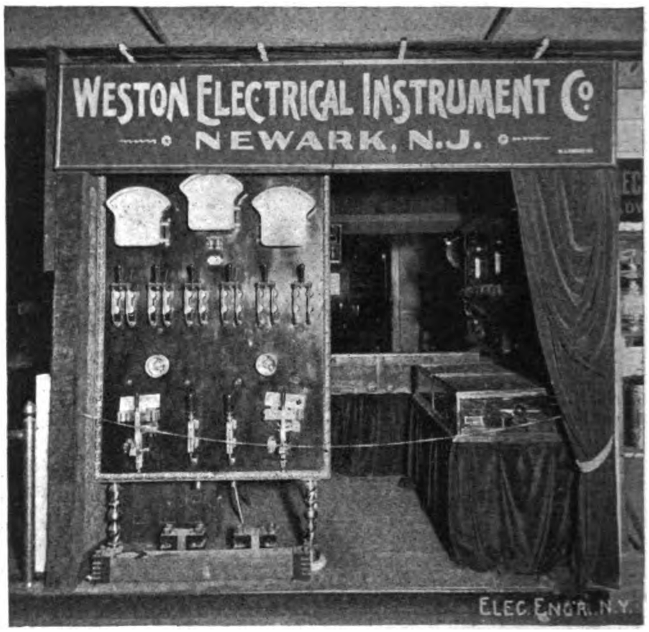
THE ADAMS BAGNALL ELECTRIC CO.'S EXHIBIT.

is called the marine lantern. It is designed for portable use on board ships. This lamp is provided with a bail, or handle, to enable a seaman to sling it on his arm and have free use of both hands in climbing masts to hang the lantern where desired for temporary use. A desirable feature of the inclosed arc is the entire absence of shadow. This, in fact, is one of the particular claims of the Adams-Bagnall Company on all of the

THE ELECTRICAL ENGINEER.

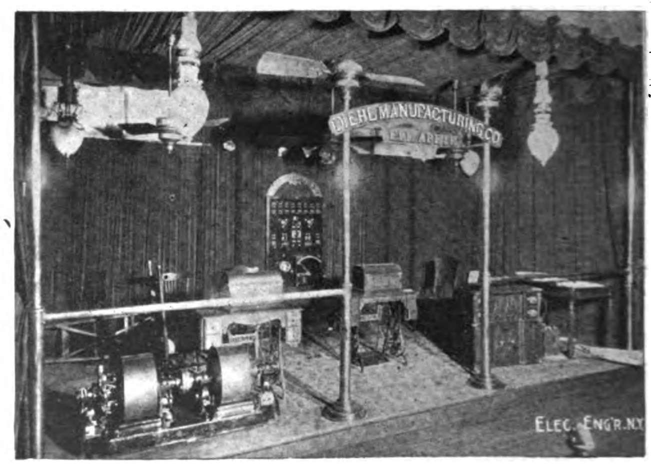
THE HOLTZER-CABOT ELECTRIC CO.

THE BIRDSALL ELECTRIC CO.



THE WESTON ELECTRICAL INSTRUMENT CO.

THE STANDARD PAINT CO. AND SCHIFF, JORDAN & CO.



THE DIEHL MANUFACTURING CO.

"A. B." arc lamps. The "A. B." lamp is a single carbon fourteen-hour lamp, focusing, and in which the globe is not removed for trimming, the carbons need no centering, and there are no rods to clean, no sliding contacts carrying current, and the lamp burns equally well with any current from four to fifteen amperes with no change in adjustment whatever. These lamps are changed from series to alternating or constant potential by simply changing spools, and the "A. B." railway lamp is changeable to constant potential or differential by changing connections only, thus making one type of lamp answer for three different circuits. There are many other features of value enumerated in their catalogue, to be had for the asking.

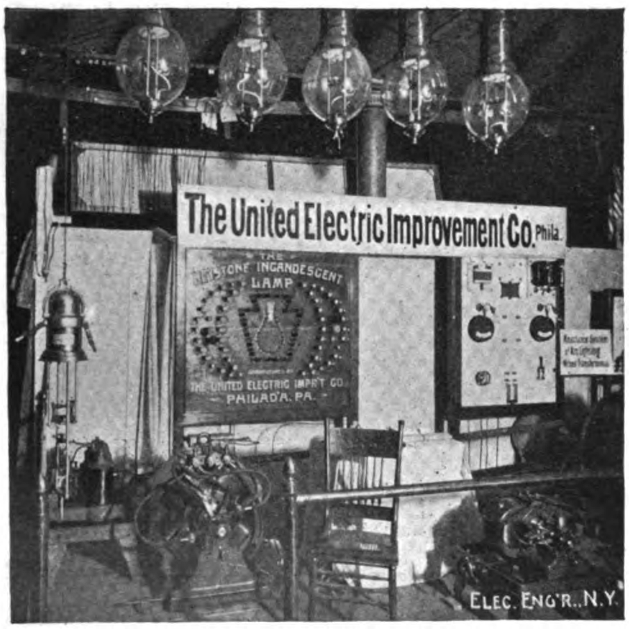
The "A. B.' incandescent lamp is also shown and attracts much favorable comment on account of the absence of the tip. It is getting to be one of the best and most favorably known incandescent lamps now in the market.

The exhibit is represented during the convention by Messrs. L. H. Rogers, E. J. Bagnall, A. B. Caldwell and A. D. Dorman. The New York office is located in the Havemeyer Building, in charge of A. D. Dorman.

The favor with which the "A. B." lamp is being received is evidenced by the large orders recently received, one of which is recorded in another column of this issue of The Electrical Engineer.

EXHIBIT OF THE UNITED ELECTRIC IMPROVEMENT CO.

THE exhibit of the United Electric Improvement Company is that of a complete plant and represents a modern installation suited for a small, scattered town. A small alternator of 40 kilowatts capacity is shown, which, at 840 revolutions per minute, will give 120 complete alternations. The main idea pervading the design of these alternators is that they shall be, above all, reliable and simple. Much of the business of the company is done with towns where plain mechanics are scarce and where good ones are not obtainable. The design of the alternator is suited exactly to these conditions. The armature is of the copper disc type—the only one manufactured



THE UNITED ELECTRIC IMPROVEMENT CO.'S EXHIBIT.

in America. The efficiency of these machines is second to none. The exciting current is somewhat higher than in machines having iron in the armature, but then there are no iron losses at all and this more than compensates for the 4 per cent. exciting current that is used in small machines. In the large machines the exciting current does not exceed 2½ per cent. of the total output. There is no heating in these machines to speak of and the output is limited only by the regulation, which is obtained without compounding.

Attention is also directed to the slow speed of these alternators. They are the only machines built the speed of which is inherently slow. The company has recently supplied a 150 kilowatt machine, directly connected to a Ball & Wood engine running at 300 r. p. m. The period of this particular machine was 100 and the exciting current was but 4½ per cent. at full load, and the inherent regulation 10 per cent. without compounding. The company does not think that this showing can be bettered anywhere. Mr. Horry, who is in charge of the exhibit, differs from some in their opinions recently advanced regarding the inductor alternator without collectors. In all of their experience, he says, the dispensing with the collectors in slow speed alternators is a purely imaginary advantage, not a practical one nor a real one. Of all the machines they have running, they have never in one instance known of the slightest hitch having ever occurred because of the collectors. The speed of their collector rings is always under 500 per minute, and with this speed the collector will outlive the attendant and will be found more reliable.

It is also the custom with many designers to ignore the iron losses that are found in alternators of the inductor type. These losses are serious enough in all alternators of the iron armature type, but they become much more so in the inductor machine with the iron stampings outside the rotary part. These losses are not so readily detected as the field losses, although they are far greater in amount and it would surprise many men to be told the true amount in horse-power that is wasted in the stamped iron of their alternators and that these losses are constant and unaffected by the load. Mr. Horry therefore regards it to the advantage of the machines of the United Electric Improvement Company that these iron losses are entirely absent.

The weight of the moving part of these machines is very small. In a 50 kilowatt machine it is only 200 pounds, not counting the shaft. This weight is so small and the speed so slow that the bearings, which are of bronze, give no trouble whatever.

These machines are built in sizes as follows: 40 kilowatts, speed 840; 50 kilowatts, speed 660; 60 kilowatts, speed 600; 75 kilowatts, speed 560; 150 kilowatts, speed 400; 200 kilowatts, speed 400; all of 120 cycles.

For direct connecting up to 200 kilowatts they run at 300 r. p. m., and give 120 volts at this speed.

The whole apparatus of the United Electric Improvement Company has been designed by Mr. W. S. Horry, who has been connected with the company for many years.

PROF. ELIHU THOMSON AT THE EXPOSITION.

ALTHOUGH Professor Elihu Thomson, of Lynn, Mass., is prevented from attending the exposition by his unfortunate accident, he is represented by one of the most interesting and attractive exhibits at the exposition—his electrical models and alternating current repulsion apparatus. These occupy a corner of the annex.

Over fifty electrical models, representing Professor Thomson's inventions, are shown. Of special interest are a dynamo built in 1876; the first spherical arc machine, built in 1879; a self-starting alternating current single-phase motor; three early forms of the Thomson recording wattmeter, including the old oscillating type; the original lighting arrester, with magnetic blow-out; a ventilated transformer of 1886; a pair of transformers used in multiple in 1879; various devices for many point arc breaking switches; an original model inductor type dynamo of 1877; a dynamo with external and internal poles; a specially compounded electric motor for constant speed; a constant current transformer; an ampere balance built in the winter of 1881; an experimental alternating current rectifier; original variable reactive coil; the early type of iron-clad dynamo of 1885—a predecessor of the spherical incandescent machine; the first three-coil machine, wound by Professor Thomson in 1879; an experimental alternating current induction motor; eleven models of arc lamps, dating as far back as 1879, and including the old differential lamp, an early form of double carbon feed lamp and a lamp made in 1884, with independent action of shunt and series coils. The original welding transformer is shown with various samples of welding and photographs of the welding transformers and dynamos of the present time, and various commercial applications of electrical welding. Altogether it is a fascinating historical exhibit, showing the results of wide research.

Professor Thomson's alternating current repulsion apparatus, which has excited universal interest, is shown in operation every afternoon and evening. This apparatus, which illustrates some peculiar phenomena, characteristic of alternating currents, consists of two sausage-shaped magnets through which a heavy alternating current passes. The repulsive force, peculiar to alternating currents, is shown by various copper rings and flat plates, which, when brought forcibly toward the magnet, are repelled or are held supported in the air.

The inductive effect is illustrated by an incandescent lamp, which is connected to a coil of wire, and which burns brightly when placed over the end of the magnet. If a copper plate is put between the lamp and the coil, the lamp burns very dimly,

THE BOYNTON MULTIVOLT BATTERY CO.

showing that only a small percentage of magnetic force passes through copper.

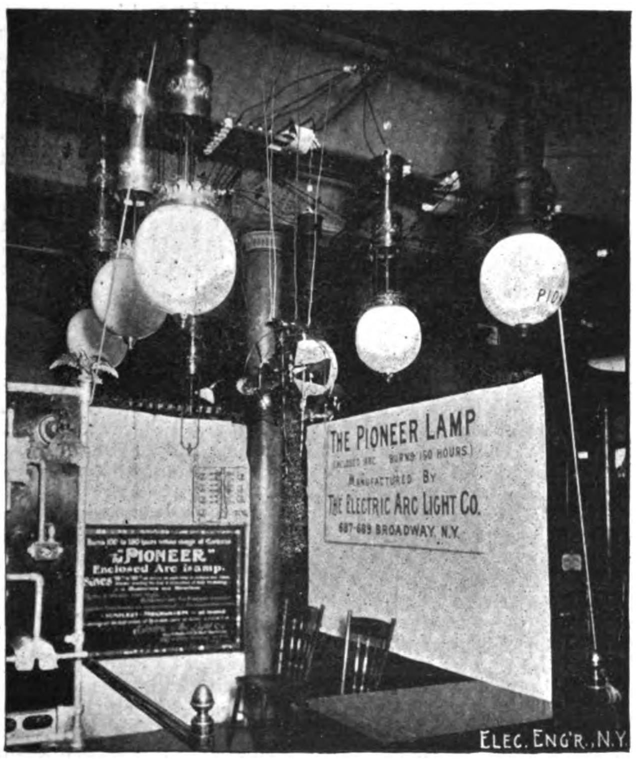
The floating lamp, burning under water, creates much surprise and comment. Various discs of copper and iron are used to show the rotary force due to alternating currents.

A great many visitors are attracted by these novel experiments. The results seem strange and startling, and interest deeply even the experts.

DR. PARK BENJAMIN'S RARE BOOKS AT THE EXPOSITION.

ALTHOUGH Dr. Park Benjamin has sent to the Electrical Exposition but a small part of his superb library of early and rare electrical books, which have served as references for his history of the intellectual rise in electricity, they fill several cases and evoke unbounded admiration. Dr. Benjamin has also greatly aided the student and visitor by grouping the books and by adding a series of useful explanatory and descriptive labels. The aim has been to open the books at some interesting page.

Probably the first printed work relating to electricity is that which appears in the 1490 edition of "The Lives of the Philosophers," by Diogenes Laertius, of which there is a unique copy in the collection. Then there is the mediæval cyclopædia of St. Isidore in the early edition of 1483, which tells all that was known of electricity up to the time of Columbus. In the same group ancient Chinese knowledge of the compass and of the use of that instrument upon land carriages is described in the first missionary translation of the Chinese classic "Shoo King." From the ancient authors one passes to the remarkable collection of original editions of the sixteenth century. In Baptista Porta's "Natural Magic" the first suggestion of the magnetic telegraph is made. In the books on "Subtlety," by Jerome Cardan, the attraction of the amber is for the first time fully differentiated from the attraction of the magnet; and, in the treatise of the Italian physician, Francastorio, the electricity of the diamond is first pointed out. There is also a copy of the letter of Peregrinus, originally written in 1269, and



THE ELECTRIC ARC LIGHT CO.'S EXHIBIT.

printed in 1558, suggesting the magnetic motor and the attraction and direction of a needle by a lodestone globe.

Then comes the actual beginning of modern electrical science. Here is the treatise of William Gilbert, written in 1600, on the magnet, wherein for the first time the word "electric" is used, and where electricity is for the first time recognized as a branch of science. Both the first and second editions of Gilbert's great treatise are exhibited, and the even more rare treatise which Gilbert left in manuscript at his death, and which was suppressed by Lord Bacon. Here, also, is a collection of little pamphlets by Ridley and Barlow, which mark the first electrical dispute. The idea of the telegraph becomes further advanced in the burlesque poems of the Jesuit Strada. It is repeated in the "Magnetic Philosophy" of Cabæus, in 1628, but that work is more remarkable because it adds to the science the first electrical discovery made subsequent to the work of William Gilbert—namely, that of electrical repulsion. Here also are the two great works of Galileo.

THE GORDON-BURNHAM BATTERY CO.'S EXHIBIT.

wherein he supports Gilbert and brings down upon himself the condemnation of the Church.

After Gilbert, Cabæus and Galileo came Paracelsus and other visionaries, who developed the notions now commonly known under the names of "animal magnetism," "hypnotism," etc. Here is a work on the magnet by Athanasius Kircher, general of the Jesuits, intended to break down the discoveries and theories of William Gilbert.

Then there are the curious books of Sir Kenelm Digby and Walter Charleton advocating what was then called the "magnetic cure of wounds."

The original edition of Charleton, published in 1650, is especially remarkable because here is used for the first time the word "electricity." Gilbert had used the word "electric" and Brown the word "electrical," but the word "electricity" had never been suggested until it appeared in Charleton's treatise.

Another book belonging to the progress of the science was the work of Descartes on "Deductive Philosophy," which had the effect of discouraging original physical research, but which, however, shows for the first time the complete magnetic spectrum.

The next advance in electrical progress is marked by the work of Otto von Guericke, which was issued in 1672. Here are described the first electrical machine ever made, electric light, electric sound, electric conduction, and electric polarity. Among the works of this group are the original English pamphlets of Robert Boyle on "The Mechanical Origin and Production of Electricity" and the works of Robert Hooke, issued in 1707, who was one of the most ingenious electrical inventors that ever lived and who suggested the phonograph. Here also are detailed the experiments of Hauksbee, who elicited and recognized the electric light produced in vacuum tubes and called the emanations from that electric light "rays."

Because of the discovery of the electric light produced from rubbed glass or amber, and because these sparks could be drawn from the fingers of electrified people, the Germans, in 1743, believed that fire existed in the human body and could be made to come out electrically. This notion created great excitement throughout Germany and set all the German philosophers hard at work upon electrical discovery. What they did is shown in another set of books.

The first book on electricity which ever came into the United States is shown here. It belonged to Benedict Arnold, the traitor, whose autograph is on the title page, and it possesses a further curious interest for all the visitors. It was a copy of this book that Benjamin Franklin studied, and his investigations culminated in his famous kite experiment and the proving of the identity of electricity and lightning. Franklin told the story of what he had done in a letter to the "Gentleman's Magazine," and the original clipping is shown in the collection. Here are also exhibited all of the original editions of Franklin's letters, in which he describes his various electrical dis-

coveries, and the French translation of them which first attracted to him the attention of European philosophers.

Of all the books of the collection none is probably so unique as that which begins the group of books which relate to the epoch of the "voltaic cell." This is the original pamphlet, written by Galvani, describing his frog experiments. But a very few copies—it is said only twelve—of this work were made, and these solely for Galvani's private use. The particular copy exhibited in Dr. Benjamin's collection not only belonged to him, but is the one on which he made the pen and ink corrections for the issue which was published during the following year. A copy of the 1792 edition, generally called the first edition, of Galvani's treatise, is exhibited in this group, and the corrections made by Galvani's own hand are duly noted.

Dr. Benjamin exhibits the first books which describe the secondary battery and the electric motor, and the exceedingly rare works in which the telegraph is first explained. A curious and most interesting relic is the original paper read by the famous French philosopher, Ampere, on the mutual action of two electric currents, which is the original document from which the author delivered his lecture, and which is annotated by himself. The first contributions to science of Michael Faraday and Joseph Henry are in the collection; so is Sir Humphry Davy's original paper on "The Safety Lamp," and there is a curious collection of early American books on electricity, dating back to 1802.

This intensely interesting collection is well set off by a group of autographs and portraits of early electrical worthies. It is not surprising to find scholars and experts bending over these cases for hours, but it gives one a new idea of the modern yearning for electrical information to see casual people studying the groups and labels, as well as the books, with rapt attention.

THE U. S. PATENT OFFICE EXHIBITS OF MODELS.

IT is difficult to find words of praise adequate to the interest, value and importance of the beautiful collection of 365 models sent by the U. S. Patent Office to the Electrical Exposition. The intrinsic value of the models alone would attract attention to them, for many of them must have cost large sums of money at the model makers'; but above all things looms the fact that here are represented the ideas and inventions upon which pretty well all the modern applications of electricity are based. The list in the official catalogue bristles with great names, and in every department one gets back to the beginnings and the fundamental ideas. Here are the first telegraphs, not omitting Bain and House and Wheatstone, or the special applications like those of Casselli, Farmer, Phelps, and others. Here are the early motors of Davenport, Jacobi, Page, Neff, Lillie, Griscom, and others. Here are the early magneto machines, not forgetting Pixii, in 1832; and here are exemplified the early dynamos of Edison, Weston, Brush, Thomson-Houston, Fuller, Hochhausen, Maxim, and the whole run of pioneers in that great field. As with the dynamos, so with the lamps and motors and systems of distribution—they are represented in these cases in profusion, and it is sometimes pathetic to note how much of spirited and talented endeavor has been absolutely thrown away in work whose outcome was failure.

There are in the collection a good many telephonic models, including some of Prof. Bell's earliest, but not forgetting those of Phelps, Edison, Dolbear, Gray, Gilliland, Brown, Eccard, and others. Even Mr. G. Westinghouse, Jr., appears to have had telephonic ambitions in his salad days, if these records in model form may be believed.

Many of the patent models shown are curious, such as one for electric whaling and another for electric weighing, or a funny one for painting telegraph wires, dated 1849. As an offset to these are the fine specimens of electric welding of Prof. Elihu Thomson, remarkably illustrative of a distinctly new art. And while mentioning this name, it is odd to see, as far back as 1879, a scheme of Thomson and Houston for the storage of electricity.

THE FISKE RANGE FINDER AT THE EXPOSITION.

One of the recent and most attractive features of the Historical and Loan Exhibit of the Electrical Exposition is the set of electric range finding apparatus designed by Lieut. Bradley A. Fiske, U. S. N., and to be placed on the big new battleship "Iowa." It is intended to measure with exactitude the range or distance of the enemy.

Two telescopes, at the ends of the ship, are fitted with contacts, which move along arcs of resistance wire, as the telescopes are directed at any object. The wires are connected together as a Wheatstone bridge, the galvanometer of which is placed in a secure place below the water line of the ship. The act of directing the telescopes towards any object disturbs the "balance of the bridge," and makes the galvanometer needle deflect by an amount proportional to the convergence of the telescopes, and inversely proportional to the distance. The scale of the galvanometer is divided into yards, so that the needle automatically points to the graduation representing the distance of the object. The operation of the device is perfect, and the simple ingenuity of the scheme pleases every electrician.

HOW THE POSTAL-COMMERCIAL MESSAGE WENT.

WE are indebted to Mr. Francis W. Jones, electrician of the Postal-Telegraph Cable Company, for the subjoined very interesting itinerary of the message sent from the Exposition Building to Tokio, Japan, and back, over the Postal wires, Commercial cables, etc.:

New York via Meadville, Pa., Chicago, Kansas City, Albuquerque, Los Angeles, to San Francisco; distance, 4,118 miles.

San Francisco via Vancouver, Winnipeg, Montreal, to Canso; distance, 4,914 miles.

Canso to London via Commercial cables and Waterville, Ireland, 2,823 miles; London to New York, 3,663 miles; total, 6,486 miles.

Grand total of message covered in four minutes, 15,518 miles.

The message from New York to Tokio, Japan, traveled as follows:

	Miles.
New York to San Francisco	4,118
San Francisco to Canso	4,914
Canso to London	2,823
London to Tokio	13,677
Tokio to London	13,677
London to New York	3,663
Grand total	42,872

OHM'S LAW AT THE SHOW.

"A Reminder of Ohm's Law," distributed by the progressive Standard Underground Cable Company, is the title of one of the novel souvenirs at the exposition, and one the most sought for by electrical people. It impresses on the mind of every one who sees it the essential primary laws of the science. It can be secured at the company's exhibit or by writing or calling at the nearest office of the company. Samples of their standard makes of lead-covered cables, the catalogue and descriptive lists attract considerable attention and are in great demand. The company is well represented by Manager G. L. Wiley, A. B. Saurman and Edward Sullivan, of New York. Mr. J. W. Marsh, the general manager of the company, has also been in attendance.

THE "ELECTROTHERM" AT THE SHOW

One of the electrical devices in operation in the exhibit of the Edison Electrical Illuminating Company at the Electrical Exhibition, is an asbestos heating pad, about a foot square, called by the makers an "electrotherm," which promises to soon become of great usefulness in all households, hospitals and sanitariums served with an electric current. The pad consists of asbestos with fine resistance wires woven into it, which become heated as the current passes through them. When uncovered the pad looks very much like, and is as soft and flexible, as a piece of asbestos cloth, but when connected to the electrical circuit by means of any lamp socket the increasing warmth gives early evidence of hidden influence. It soon becomes apparent that this pad, with its uniform and continued temperature, which may easily be regulated by turning a simple switch, is well adapted to displace the heretofore troublesome water bottles and compresses with their decreasing and violently fluctuating temperatures, and so add materially to the comfort and health of the invalid, while at the same time safely diminishing the care and responsibility of the nurse. The electrotherm should prove most valuable in cases of sickness, such as rheumatism, cramps, diphtheria, pneumonia, severe colds, cold feet and numerous other ailments which sooner or later become a part of everybody's experience, and which have heretofore been inadequately treated with the inconvenient water bottle or plaster; and, especially in severe or serious cases, where a prolonged and even temperature may be desired or positively necessary. The electrotherm is light in weight and cleanly, and requires no preparation other than attaching to an electrical fixture the flexible cord furnished for the purpose. It is made in several forms, one of which has a neat cane cover, and is designed as a

foot warmer and for warming beds or dishes. There are many instances where the electrotherm has proven its great convenience and efficacy in affording relief to invalids or those temporarily injured, and it may readily be imagined that in the not very distant future it will be the electrically-heated pad which will have an indispensible place in the household instead of the old-fashioned, clumsy and inelegant water bag.

LIBEL SUIT BROUGHT BY THE EXPOSITION CO.—THE NIAGARA TRANSMISSION.

THE National Electrical Exposition Company, through their counsel, J. G. Wells, 10 East Fourteenth street, brought suit last week in the Supreme Court against the W. J. Johnston Company, publishers of the "Electric Railway Gazette" and the "Electrical World," for $50,000 damages for libel, the suit being based upon an article in the last issue of the first-named paper, charging that the exhibition of Niagara power transmission at the Electric Show was in the nature of a "fake" and a "gigantic fraud" upon the public.

The officers of the National Electrical Exposition Company

THE CALCULAGRAPH EXHIBIT AT THE NATIONAL ELECTRICAL EXPOSITION.

are: H. J. Smith, general superintendent of the Edison Illuminating Company, of New York; W. F. Weiss, vice-president of the New York Steam Heating Company; George F. Porter, secretary of the National Electric Light Association; C. O. Baker, Jr., of the Baker Platinum Refining Company; R. B. Corey, General Incandescent Arc Light Company; H. L. Lufkin, Crocker-Wheeler Electric Company, and E. F. Peck, of the Peck Electric Company.

Mr. Johnston, upon learning of the publication in his paper, immediately made the following apology and retraction:

"In the 'Electric Railway Gazette" of May 10 appeared an item, written immediately after the opening of the Electrical Exposition, saying that the success of the experiment in the transmission of electric power from Niagara to New York savors strongly of 'fake.' The author of the paragraph believed at the time that he had grounds for making the assertion. He has since made a thorough examination of the circumstances, however, and satisfied himself that he was entirely mistaken in what he said, and a correction will be made in the next issue of the 'Gazette,' dated May 25. I need not add that both the author of the item and I regret the appearance in an electrical journal of anything that might be construed as a reflection upon the good faith of the well-known companies and gentlemen to whose efforts are due the success of the Niagara transmission. (Signed) W. J. Johston, Editor, 'Electric Railway Gazette.' "

Mr. L. B. Stillwell, electrical engineer, of the Westinghouse Electric & Manufacturing Company, also signed a statement as follows: "The power used to operate the small Tesla motor at the Electrical Exposition comes from Niagara. During the evening it is transmitted over a circuit consisting of three conductors. Two of these are wires ordinarily used for telegraphic purposes by the Western Union Telegraph Company. The third is the earth. In technical language, it is a case of tri-phase alternating current transmission. For a time direct or continuous current was used.

"When the alternating current is in use the potential as measured across any two conductors at the Niagara end of the line is approximately five hundred (500) volts. The currents are delivered to the Exposition Building at a potential approximating two hundred and fifty (250) volts.

"The gentlemen in charge of this undertaking have accomplished precisely what they undertook to accomplish and the transmission is an unqualified success. (Signed) L. B. Stillwell."

Mr. T. C. Martin was also asked for a statement, which is here appended: "For nearly a year past I had believed it possible to deliver Niagara energy over wire, at the exposition, and some months ago set out to do it, by securing a small model of the Niagara power plant, to begin with; then permission from the Niagara Falls Power Company to connect with the power house; Tesla apparatus from the Westinghouse Electric & Manufacturing Company for the transmission to the model; two wires from the Western Union Telegraph Company; and wires from the American Telegraph and Telephone Company (long distance telephone) to transmit the roar also to the model. The plan has been, to my positive knowledge, carried out, as I have personally watched the accomplishment of my plan. The electrical engineers co-operating have been Mr. A. S. Brown, of the Western Union Company; Mr. Nikola Tesla, Mr. L. B. Stillwell, of the Westinghouse Company, assisted by Messrs. Maclaren and Zimmerman, and F. A. Pickernell, of the Long Distance Telephone Company.

"I would add that as the Western Union wires are available only in the evening, I carried out the suggestion of Mr. A. S. Brown, of sending storage batteries to Niagara to be charged, so that the model could also be run in that way for the benefit of day-time visitors, who might otherwise be disappointed. This difference of method in day-time and at night has been carefully explained in labels and printed statements, so that there could be no doubt or misapprehension as to the facts.

"The Niagara transmission over Western Union wires has been a great success, doing far more than was expected. In fact, failure was freely predicted by many. (Signed) T. C. Martin, Editor The Electrical Engineer."

It should be mentioned that in reality three motors have been run from Niagara, namely, the Tesla, by alternating current, and a Lundell and a Crocker-Wheeler by the direct. The last were on during the trial tests just before the opening of the show.

"THE HOSPITAL WARD."

The Practical Electrical Laboratory at the exposition has been carried on with great success by Mr. Max Osterberg and his assistants, and is often more crowded than any other part of the exposition, especially when the rare phosphorescence of the diamond is shown in the Tiffany booth, or some experiments are being conducted with the beautiful Doremus apparatus. There is also a Röntgen X-ray exhibit, which has been in such frequent demand by visitors with inquiries, bullets in their bodies, etc., that the habitués of the exposition have dubbed it "The Hospital Ward." Hardly a day goes by when Mr. Osterberg or Mr. O'Connor is not requested by somebody to find out where that needle or bullet may be located. And every trial has been successful.

STORAGE BATTERIES AT THE SHOW.

THE extensive exhibit of the Electric Storage Battery Company at the exposition was added to last week by the installation of apparatus showing the formation of storage battery plates by the Planté process.

In a glass jar filled with electrolyte, two lead plates were immersed, the terminals being connected to a battery of chloride accumulators. Through a large magnifying glass placed in front of the jar, the action of the current on the lead was plainly discernible. It has proved an interesting feature to the crowds which watch it during the evening.

The electric launch in the company's exhibit has had a captain added to its equipment, in the person of a very small colored boy dressed in a "middy's" uniform of white duck, and with the words "Chloride Accumulator" on the front of his sailor hat.

The Chloride accumulators furnished the current to operate the telegraph instruments that started the messages around the world, and also for firing the guns that announced the departure and arrival of messages.

THE PERU ELEC. MFG. CO.

The exhibit of the Peru Electric Manufacturing Company, described in our last issue, is illustrated in the present number. The company not only make a beautiful and highly creditable display of their specialties, but are also advertising their porcelain in a decidedly novel way. Mr. Stevens, who represents the company, has favored us, among others, with a dainty inkstand, in the shape of an insulator made of Peru superior porcelain, capped with a removable slotted piece, and mounted in a nickel circlet supported by three handsomely turned binding posts, which serve as legs. The name of the company is stamped on the circlet. The inkstand is a useful souvenir as well as a good advertisement. It is needless to say that it is being much sought after and that the supply is necessarily far short of the demand.

Little three-year-old Helen Stevens is quite a drawing card at the company's booth, where she amuses herself nearly every evening with carbons, porcelains, binding posts, screws and screwdrivers, and other trade supplies, and attracts much attention by her prettiness and dexterity. She is known as the "Little Electric Girl," her only rival being the bright little chap, a year or two her senior, at the Birdsall Electric booth, who lights up his nose and mouth good-naturedly for the benefit of the passers-by.

THE W. J. HAMMER COLLECTION AT THE EXPOSITION.

We have already published details with regard to the fine exhibit made at the exposition in the Historical and Loan Department, by Mr. W. J. Hammer, and refer to it now only to say that that gentleman has supplemented his original display by many other things of equal interest and importance. The lamp and portrait collections are all that was expected, and daily attract large crowds.

Mr. Hammer has also added a handsome little case of historical wires, which have now been used both in connection with the opening of the show and the dispatch of the message around the world, the various sections having been electrically welded so that they would constitute continuous parts of the circuit. The wires are as follows:

1. Section of the wire over which Prof. Samuel F. B. Morse sent the first message by means of the Morse telegraph. 2. Section of the wire over which audible speech was for the first time transmitted by means of the Bell telephone by Prof. Alexander Graham Bell. 3. Section of the Atlantic cable through which the first cable message was sent across the ocean by Cyrus W. Field. 4. Edison plug and section of wire through which was lighted the first incandescent lamp ever lit from an electrical lighting central station. 5. Section of the first trolley circuit put up at the historic Richmond, Va., electric railroad by F. J. Sprague. 6. Section of the wire through which the current of electricity was sent by President Cleveland when he opened the World's Fair, at Chicago. 7. Section of the wire through which the electricity was sent to illuminate the headquarters of the American Institute of Electrical Engineers by Moore's system of vacuum tube lighting, this being the first room in the world so lighted. 8. Section of the cable through which the first current of electricity was transmitted from Niagara Falls electric power plant, April 16, 1895.

NOTES OF EXHIBITS.

THE STRAIGHT LINE ENGINE COMPANY are showing in space E 12 a 125 horse-power engine with a well-built General Electric 75 kilowatt generator.

THE WESTON ENGINE COMPANY, of Painted Post, N. Y., are operating a 90 horse-power engine at 280 revolutions per minute, belted to a Warren alternator. The engine runs at 280 revolutions and is in charge of Mr. John Harvey.

THE FUEL ECONOMIZER COMPANY have an exhibit which has proven particularly interesting to those engaged in central station work, as showing the economy which may be the portion of every central station manager by means of their device in connection with the boilers. The merits of the Fuel Economizer have been conscientiously portrayed to the visitors who have attended the exhibition.

THE KENNEDY VALVE MANUFACTURING COMPANY, of New York, show a line of their high pressure valves with by-pass, which stand 250 pounds to the square inch, valve posts with lock attachment, which are new and are shown for the first time, indicator valves, etc., all of which, as they say, are specially designed to meet the requirements of modern power plants. Mr. Hartenfels is in charge of the exhibit, and one of the features of the exposition is that several of the valves are used in the steam part.

W. F. BOSSERT, Utica, N. Y., has his exhibit in charge of his agents, C. C. Sibley & Company, 329 Fourth avenue, New York. It consists of a good sized line of junction, outlet, and switch boxes, showing one of the best methods of fireproof construction for iron and brass conduits. This display has attracted the attention of many engineers and contractors, the goods showing points of considerable merit. Messrs. C. C. Sibley & Company, aside from being the agents here for Mr. Bossert, have also the New York City sales agency for the General Electric Company.

THE DIAMOND ELECTRIC COMPANY, of Peoria, Ill., exhibit their specialty, alternating meters and transformers. Their display in the gallery of the exhibition is an interesting one, showing an assortment of meters and transformers from 10 to 300 lights capacity. Uncovered meters are shown in full operation, also transformers with the cases removed, showing the arrangement of coils and method of construction. Copies of tests of their different apparatuses are given away at the booth, which certainly speak volumes for the goods this firm manufacture. Mr. S. R. Sheldon has charge of their exhibit.

THE PENNSYLVANIA SLATE COMPANY, Cotton Exchange, have an attractive booth, showing samples of plain and marbleized slate. In order to be effective, slate for insulating purposes must be entirely free from any trace of metal, and in this respect the company claim their product to be preeminent, it being entirely free from the risk of short circuiting. Some very pretty specimens of marbleized slate are shown, it being extremely difficult to distinguish it from the genuine marble. The company solicit correspondence and will take pleasure in mailing descriptive matter and pamphlets on application.

TELMIC MANUFACTURING COMPANY, 52 New street, New York, with factory at Carteret, N. J., have a neat exhibit of their glazed firebrick clay conduits. This article they manufacture in various patterns, to be used in buildings as well as underground conduiting. A part of the wire from Niagara Falls to the exhibition building passes through conduits of this firm's make. The Telmic Manufacturing Com-

pany's product, although a comparatively new article on the market, shows decided merit and ought certainly to bring this firm a prosperous future. The exhibit is in charge of Mr. Walther H. Falconer.

THE AMERICAN STOKER COMPANY, of Dayton, Ohio, exhibit their boiler stoker. This is a gas machine pure and simple. The coal is carried back and forced upward at the same time by a tapered conveyor or screw. The green coals as they are forced up are coked by the incandescent coke bed above, the gases being released at this point, and as they pass up through the upper coke bed come in contact with the forced draft that is used in connection with the stoker, combustion then taking place. The combustion is so thorough that nothing but a clinker is left at the end of the day. The machine has been examined and commended by leading mechanical engineers.

A. A. GRIFFING IRON COMPANY, the most widely known and largest manufacturers of radiators and heating apparatus, are exhibiting the Baudy steam traps on the floor of the generating exhibit. This clever device is manufactured by them under the Littlefield patents, and is fast supplanting pumps for feeding boilers, for returning water of condensation to a boiler, no matter what pressure of steam is carried on the boiler. The A. A. Griffing Company, manufacture this specialty in conjunction with their other goods at their extensive plant in Jersey City, N. J. Their New York office, 66 to 68 Center street, will take pleasure in sending descriptive circulars and catalogues to any address upon application.

JOHN SIMMONS COMPANY, 106 Centre street, New York, the well-known wrought iron pipe concern, have an extensive display of their wares on the generating floor of the exhibition. Their exhibit comprises wrought iron pipe and fittings of standard and extra heavy weight; brass and iron cocks for high pressure work; tubular poles for railway and telegraph use, and a new feature, tubular framing for stone switchboards and partitions—an appliance of decided merit. This firm report doing a steadily increasing business in tubular iron poles for railway and telegraph use both in this country and abroad. The superiority of these poles shows itself in many ways. The cost is but a trifle higher than that of wooden poles.

THE GOULDS MANUFACTURING COMPANY, Seneca Falls, N. Y., with office at 16 Murray street, New York City, exhibit an interesting line of their celebrated triplex power pumps. Working models of their electric house pumps for tank service are shown in full operation. Photographs of some of their notable installations for waterworks and mine pumping cover the walls of the booth. The exhibit attracts the attention of a large number of visitors. Their electric mechanism is fast displacing the gas and hot air engine for pumping purposes as applied to private and business houses in large cities with inadequate water pressure. The "Goulds Efficient Power Pump" catalogue, an exhaustive work on their articles of manufacture, will be sent to any address on application.

THE AMERICAN WATCHMAN'S TIME DETECTOR COMPANY, J. S. Morse, treasurer, 234 and 235 Broadway, New York, exhibit their well known time detector, operated by battery and magnets, of which they have more than 8,000 in use all over the country. This firm takes pride in having it known that their watchman's clocks are used in nearly all the great electrical concerns, including the private laboratory of Mr. Edison, at Orange, N. J. They have also on exhibition a master clock driving the secondary clocks similar to the one in use in the Boston State House, where over 200 secondary clocks are in circuit. This is said to be the largest of its kind in this country. Three different kinds of employés' time recorders are also shown, and a new school programme clock, which rings simultaneously a varied programme in different rooms automatically for the assembling and dismissing of classes. This it does without resetting, for the entire school term. The exhibit is in charge of A. G. Morse, R. H. Smith and C. C. Bangs.

THE WILKINSON MANUFACTURING COMPANY, whose advertisement appears on another page, have their stokers in active operation at the exhibition. This stoker is certainly one of the best ever brought on the market and proves everything its inventor, Mr. Wilkinson, claims for it. The construction is so perfect, any interested person can readily recognize the saving of money in fuel, repairs to boilers and brick work. One of the greatest advantages claimed, however, is that it will burn low grade fuel with better economy than results from hand firing with high priced fuel. The Wilkinson Manufacturing Company, whose plant is at Bridgeport, Montgomery County, Pa., have a large force constantly busy turning out the numerous orders placed with them from some of the largest concerns in the country. The patronage of such users as the Philadelphia Traction Company, Pencoyd Iron Works, Baldwin Locomotive Works, and Pennsylvania R. R., speaks volumes for the stoker. Pamphlets and descriptive circulars will be sent to any address on application.

PERSONAL.

PROF. HAROLD B. SMITH, of Purdue University, has been elected to the new chair of electrical engineering recently established at the Worcester, Mass., Polytechnic. He is a graduate of Cornell, a young man, and highly spoken of. His term of duty will begin in July.

SOCIETY AND CLUB NOTES.

ANNUAL MEETING OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE annual meeting of the American Institute of Electrical Engineers was held at the National Electrical Exposition, by courtesy of the Exposition management, on May 19 and 20. There was a good attendance and brisk discussion throughout. The ticket elected is as follows: President, Louis Duncan; vice-presidents, Charles P. Steinmetz, Harris J. Ryan, Wilbur M. Stine; managers, John W. Lieb, Jr., F. A. Pickernell, William L. Puffer, L. B. Stillwell; secretary, Ralph W. Pope; treasurer, George A. Hamilton.

The hold-over vice-presidents are A. S. Hibbard, Dr. M. I. Pupin, and W. F. C. Hasson; and the hold-over managers are C. S. Bradley, W. B. Van Size, Carl Hering, and Dr. Cary T. Hutchinson.

ANNUAL REPORT OF COUNCIL OF THE A. I. E. E.

The annual report submitted by the Council covers the work of the Institute for the year ending April 30, 1896. The Council has held ten regular meetings and one special meeting. Prof. A. C. Perrine was appointed local secretary for the Pacific coast region, and on the resignation of Mr. B. J. Arnold, the office of local honorary secretary at Chicago was filled by Prof. W. M. Stine.

A Committee on Incorporation was appointed in December, and after a careful investigation of the subject the Institute was incorporated under the laws of the State of New York, on March 16, 1896.

The membership of the Institute shows a gain of 91 over the previous fiscal year and amounted to 1,035 on April 30, which is classified as follows: honorary members, 2; members, 333; associate members, 700. The treasurer's balance sheet for the fiscal year ending April 30, 1896, showed a balance on hand of $239.99. The building fund reported by the treasurer amounts, with accrued interest, to $939.48.

PLANS FOR THE NEXT AMERICAN STREET RAILWAY CONVENTION.

WE are in receipt of a letter and circular from the American Street Railway Association, as to its St. Louis convention, October 20, and four following days.

The building in which the association will hold its convention is the one erected by the Republican National Convention and is 260 x 180 feet. About eighty feet of the length of the building will be partitioned off for the sessions of the convention, leaving 180 feet square for exhibits, and all entrance to and egress from the convention will be through the exhibition hall. There will be no choice of space, every place on the floor being equally desirable. Exhibits of like character will be grouped together, and space will be assigned in the order of application. Wires carrying current will be brought into the building from street railway circuit, the voltage being 550, so that all mechanical devices may be operated. The income from sale of space will go to the American Street Railway Association. The executive committee of the association has fixed the price at 10 cents per square foot, and ruled that no space of less than 100 square feet will be assigned, but applicants may have as many multiples of this quantity as they may wish, all in one body. Payment for space should be made to Mr. T. C. Penington, secretary and treasurer of the American Street Railway Association, 2020 State street, Chicago, Ill., on or before October 1, 1896. Application for space should be made to Mr. George W. Baumhoff, chairman Com-

mittee on Exhibits, Park and Vandeventer avenues, St. Louis, Mo. Space must be applied for by August 15. "Assignments will be made as promptly as possible after that date, and exhibitors notified of their location." It is earnestly requested that all exhibits shall be in place and all work finished by Monday evening, October 19, which is the evening prior to the opening of the convention. Possession of the hall can be had on Friday, October 16, thus giving ample time for preparation. Watchmen will be in charge of the premises, so that exhibits will be safe.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MAY 5, 1896.

Alarms and Signals:—

INDICATOR FOR BOWLING ALLEYS. F. Becker, North Plainfield, N. J., 559,352. Filed April 24, 1895.
Means for throwing pin indicator when circuit is broken, said circuit being completed by metallic plate on bottom of pin resting on electrodes at suitable place in the alley.

INDICATING AND REGISTERING APPARATUS FOR METERS. P. Marix, Paris, France, 559,394. Filed Dec. 27, 1895.
A clockwork mechanism of a diagram chart in the form of a paper roll mounted on a horizontal arbor of said clockwork mechanism, a marker carried by a vibratory arm and bearing with light friction upon said roll, and means for shifting the arm.

ELECTRIC SIGNALING APPARATUS. T. G. Morse, Erie, Pa., 559,397. Filed Oct. 3, 1895.
For fire alarm purposes.

AUTOMATIC TIME RECORDING INSTRUMENT. H. F. Eaton, Quincy, Mass., 559,518. Filed March 20, 1893.
The recording sheet is moved only during the time a signal is being received.

ELECTRIC RAILWAY SIGNAL SYSTEM. L. J. Everest, Omaha, Neb., 559,576. Filed July 12, 1895.
Comprises a train of gearing actuated by a car wheel to permit a suspended terminal to drop, thus completing the circuit.

SWITCH AND SIGNAL MECHANISM FOR RAILROAD CROSSINGS. J. G. Schreuder, Wilkinsburg, Pa., 559,613. Filed March 31, 1893.
Mechanism for shifting the movable rails into line with the main rails and a lock operated by cars on the other line of track for holding the movable rails in derailing position.

BLOCK SIGNALING ON RAILWAYS. J. G. Dixon, Huddersfield, England, 559,688. Filed Nov. 25, 1895.
Consists in recording the number of wheels that pass out of a block section and the number of wheels that enter beyond the home signal of the next block station.

Conductors, Conduits and Insulators:—

CONDUIT FOR ELECTRIC LINES. J. Graizier, Geneva, Switzerland, 559,701. Filed Nov. 4, 1895.
The conductors rest on terra cotta cross-bearers and a layer of broken pieces of refractory insulating material is laid beneath and above the conductors.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. J. F. Kelly, Pittsfield, Mass., 559,530. Filed Nov. 20, 1895.
For alternating currents of different phase having an otherwise normally unbalanced mutual induction; a balancing transformer having its coils in series, respectively, with the mains carrying the currents of different phase.

SYSTEM OF ELECTRICAL DISTRIBUTION. B. G. Lamme, Pittsburg, Pa., 559,721. Filed April 11, 1895.
Means for changing the phase and wave form of alternating electric currents comprising two transformers, each of which is provided with two secondaries, those of one being respectively connected directly and reversely in series with those of the other.

Dynamos and Motors:—

ELECTRIC MOTOR AND MOTOR GENERATOR. L. Gutman, Chicago, Ill., 559,380. Filed July 10, 1894.
A self-starting synchronous motor, and a motor generator adapted to be supplied with a uniphase alternating current and to supply current to translating devices in a working circuit.

INDUCTOR DYNAMO. C. P. Steinmetz, Schenectady, N. Y., 559,419. Filed Feb. 15, 1896.
Inwardly projecting pole pieces provided with field magnet windings, armature coils mounted upon the polar faces, and a revolving inductor.

DYNAMO ELECTRIC MACHINE. J. F. Kelly, Pittsfield, Mass., 559,531. Filed Jan. 18, 1896.
An armature, consisting of two stationary laminated rings, having between them a magnetic bridge formed of bolts or bars.

PILLOW BLOCK FOR DYNAMO ELECTRIC MACHINES AND MEANS FOR SUPPORTING SAME. P. W. Power, Pittsfield, Mass., 559,538. Filed Feb. 19, 1896.
Two bars extending through the machine so as to have ends protruding from each end of the machine, in combination with a pillow block supported from said protruding ends.

DYNAMO ELECTRIC MACHINE. J. F. Kelly, C. C. Chesney and P. W. Power, Pittsfield, Mass., 559,584. Filed Jan. 22, 1896.
A revolving inductor having polar projections with a stationary armature, and energizing coil, and a stationary copper ring surrounding the revolving inductor.

ARMATURE FOR ELECTRIC MOTORS AND DYNAMOS. J. P. B. Fiske, Alliance, O., and H. A. Littlefield, Lynn, Mass., 559,692. Filed Dec. 14, 1894.
An armature core or drum having annular extensions at its ends, and a series of coils disposed on said core or drum and having their ends disposed on said annular extensions.

Electro-Metallurgy:—

APPARATUS FOR PRODUCING ZINC AND LEAD BY ELECTROLYSIS. R. O. Lorenz, Göttingen, Germany, 559,729. Filed Jan. 4, 1895.
Consists in converting the compounds containing zinc and lead into chlorids, which are subjected to an electrolytic process under the influence of heat.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. A. Jordan, Vienna, Austria-Hungary, 559,387. Filed Feb. 12, 1896.
Relates to feed mechanism for carbons.

ELECTRIC LIGHT ATTACHMENT FOR GAS FIXTURES. P. W. Remig, Brooklyn, N. Y., 559,403. Filed Jan. 25, 1895.
Details of construction.

ELECTRIC ARC LAMP. C. E. Scribner, Chicago, Ill., 559,407. Filed Dec. 30, 1893.
An automatic cut-out adapted to be brought into operation by any abnormal increase of the resistance of the main circuit through the lamp carbons.

ELECTRIC ARC LAMP. C. E. Scribner, Chicago, Ill., 559,408. Filed Jan. 9, 1894.
Similar to above.

ELECTRIC ARC LAMP. R. Segerdahl, Chicago, Ill., 559,412. Filed Sept. 10, 1895.
Employs a flexible carbon rod.

LAMP SOCKET. W. C. Wirt, Schenectady, N. Y., 559,474. Filed Feb. 8, 1896.
A key shaft formed with projections adjacent to its ends struck up from the key shaft and serving to retain the key shaft in its frame.

ELECTRIC ARC LAMP. M. Wheless, Washington, D. C., 559,648. Filed Dec. 7, 1895.
The combination of the feed yoke, the cap or dome, the counterweight track jointed to both the dome and the yoke, and the counterweight carried by and freely movable on said track.

ELECTRIC ARC LAMP. M. Wheless Washington, D. C., 559,649. Filed Jan. 29, 1896.
Designed to enable a lamp to be used on either an arc or incandescent circuit.

ELECTRIC ARC LAMP CARBON. J. Roubal, Prague, Austria-Hungary, 559,752. Filed Dec. 27, 1895.
The surface is incrusted with a mixture of pure carbon and a silicate or boric acid.

Miscellaneous:—

COMPOSITION FOR ELECTRIC INSULATION AND PROCESS OF MAKING SAME. A. Gentzsch, Vienna, Austria-Hungary, 559,376. Filed April 5, 1893.
A composition of matter for electric insulation consisting of shellac and rosin, of birch tar oil and anilin oil, and of arthracene.

PROCESS OF AND MEANS FOR PRODUCING BLEACHING AGENTS. C. Kellner, Vienna, Austria-Hungary, 559,454. Filed Nov. 1, 1892.
Consists in subjecting a solution of chlorids of the metals of the alkalies to the action of an electric current and combining the chlorine liberated at the anode with the alkaline hydrate formed at the cathode in a separate vessel.

ELECTRICAL SAFETY LOCK FOR ELEVATORS. A. C. Hunt, Denver, Colo., 559,529. Filed Jan. 17, 1896.
Actuated by an electric current controlled by the opening of the elevator shaft door.

ELECTRIC BELT. G. N. Moore and R. C. MacCulloch, New York, 559,535. Filed April 17, 1895.
The belt web is folded along the middle lengthwise, and the battery cells having a perforated attaching flange secured to one of the folded parts, and said parts being laced along the open edge.

ELECTRIC HEATER. W. F. Warner, Muncie, Ind., 559,553. Filed Aug. 2, 1895.
A conductor coil, a block forming a non-conducting surface secured in the casing and having a notch at each end and a projection extending out from the notch around which the conductor coil is adapted to be passed.

SAFETY APPLIANCE FOR ELEVATORS. J. H. Tennyson, New York, 559,633. Filed April 20, 1895.
An electric locking device operates a steam supply valve.

Railways and Appliances:—

ELECTRIC RAILWAY. H. Brandenburg, Chicago, Ill., 559,356. Filed March 11, 1895.
A conduit comprising an open slotted metal tube.

ELECTRIC RAILWAY. H. Brandenburg, Chicago, Ill., 559,357. Filed May 2, 1895.
A conduit forming a support for or a part of one of the track rails.

TROLLEY WHEEL. J. McKenna, Johnstown, Pa., 559,461. Filed March 2, 1896.
Comprises a separable, composite flange composed of a disc of copper or similar metal and a supporting disc of substantially the same diameter.

ELECTRICAL CONTACT DEVICE FOR SUBWAYS OR CONDUITS. A. S. Kortz, Springfield, O., and W. P. Allen, Chicago, Ill., 559,586. Filed Nov. 14, 1895.
Consists essentially of spring standards having contacting shoes.

Regulation:—

ELECTRIC CURRENT REGULATOR. A. S. Kortz, Springfield, O., 559,585. Filed Jan. 22, 1894.
Employs a solenoid arranged in the main circuit.

Switches, Cut-Outs, etc.

RHEOSTAT. W. S. Andrews, Schenectady, N. Y., 559,349. Filed Dec. 12, 1895.
A resistance card of insulating material wound with a metallic conductor, and folded upon itself lengthwise so as to bring the ends of the conductor at one end of the card.

ELECTRIC PUSH BUTTON. G. J. Soper, Brooklyn, N. Y., 559,416. Filed May 17, 1895.
Has for its object the hiding of the fastenings of the base plate.

RHEOSTAT. H. P. Davis, Pittsburg, Pa., 559,685. Filed July 10, 1895.
Comprises a plurality of sets of resistance coils arranged eccentrically, two sets of metal plates, respectively connected to the opposite ends of said coils, whereby said coils are joined in series, and a set of contacts directly attached to and supporting one set of said plates.

Telegraphs:—

TELEGRAPHIC KEY. C. G. Burke, Brooklyn, N. Y., 559,479. Filed Nov. 21, 1895.
Involves a coil of wire placed in a magnetic field, adapted by the passage through it of an electric current, to be moved or rotated in such field.

Telephones:—

SWITCHBOARD FOR TELEPHONE EXCHANGES. J. P. Davis, New York, 559,366. Filed Aug. 10, 1895.

A call-receiving board at which all the subscribers' calls are received and from which they are distributed in a uniform manner to the different operators at the multiple board.

SWITCHING APPARATUS FOR TELEPHONE EXCHANGES. J. P. Davis, New York, 559,367. Filed Aug. 10, 1895.

A device for permitting the subscriber to designate to a central station a particular group of subscribers, among which the desired correspondent may be found.

TELEPHONE CIRCUIT FOR POLICE BOXES. C. E. Scribner, Chicago, Ill., 559,409. Filed Jan. 26, 1894.

Eliminates the resistance of the electromagnet from the telephonic circuit while the telephone is in operation.

APPARATUS AND CIRCUIT FOR TELEPHONES. C. E. Scribner, Chicago, Ill., and F. R. McBerty, Downer's Grove, Ill., 559,410. Filed Jan. 8, 1895.

Means for preventing the transmission to a telephonic circuit of rapidly alternating currents, such as are capable of producing sounds in a telephone.

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., and F. R. McBerty, Downer's Grove, Ill., 559,-411. Filed Feb. 28, 1895.

Adapted to respond to currents in the time circuit and control subsidiary signals, preferably incandescent lamps, for indicating the signal for disconnection.

TELEPHONE TRANSMITTER. L. D. Appleman, Waynesborough, Va., 559,476. Filed May 25, 1895.

A suspended conducting pencil, having its end projecting between the diaphragm and a fixed electrode bearing against the latter.

SYSTEM OF CURRENT SUPPLY FOR TELEPHONES. C. E. Scribner, Chicago, Ill., 559,616. Filed Jan. 8, 1895.

A condenser is interposed in the conductor and the common source of current supply is connected with the severed portions of the conductor through impedance coils.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MAY 12, 1896.

Alarms and Signals:—

DOOR HANDLE WITH ELECTRIC ALARM. A. J. Moulart, Paris, France, 560,043. Filed July 1, 1895.

Details of construction.

ELECTRIC CALL BELL. F. C. Jordan, Wadsworth, O., 560,006. Filed March 20, 1896.

The alarm is given, when desired, by a clock previously arranged for a determined time.

RAILWAY SIGNAL. D. C. Stewart, Warren, O., 560,071. Filed March 9, 1894.

Comprises a depressible bar in juxtaposition to one of the rails of a track and designed to engage the beveled shoulder of a pivoted spring-held arm.

AUTOMATIC RAILWAY SIGNAL SYSTEM. J. W. Lattig, South Bethlehem, Pa., 560,102. Filed April 10, 1896.

A system in which the signal is controlled through the instrumentality of a relay included in a track circuit.

Distribution:—

ALTERNATING CURRENT SYSTEM OF DISTRIBUTION. C. P. Steinmetz, Schenectady, N. Y., 559,913. Filed Feb. 5, 1896.

Comprises transformers having their primaries connected in delta, and their secondaries in "Y," and a neutral or equalizing wire extending from the common junction of the secondaries only.

Dynamos and Motors:—

ARMATURE FOR DYNAMO ELECTRIC MACHINES. H. G. Reist, Schenectady, N. Y., 559,910. Filed Jan. 31, 1896.

An armature spider having a central boss or hub, separate arms radiating therefrom, the arms being provided upon their outer ends with dovetail grooves, and laminæ having dovetail projections fitting in the grooves, thus connecting the arms.

DYNAMO ELECTRIC MACHINE OR ELECTRIC MOTOR. O. Patin and L. Levavasseur, Paris, France, 560,006. Filed June 19, 1893.

A fixed inductor having eight poles alternately positive and negative, a moving armature consisting of ten flat coils and a commutator with conductors for connecting the commutator with the armature coils.

Lamps and Appurtenances:—

ELECTRIC LIGHT FOR BICYCLES. B. B. Hoffman, New York, 559,801. Filed May 24, 1895.

A lantern case, a reflector removably secured therein, spring clips in said case, a lamp socket secured by said clips in said case, a lamp socket secured by said clips beneath said reflector, and a lamp carried in said socket and extending through the lower wall of said reflector.

ELECTRIC ARC LAMP. S. E. Nutting, Chicago, Ill., 559,863. Filed Oct. 18, 1893.

The combination of an arc drawing magnet, a shunt circuit around the arc, and means operated by the magnet for varying the resistance of the shunt circuit around the arc.

ELECTRIC ARC LAMP. A. O. Mackin, Anderson, Ind., 560,039. Filed Oct. 3, 1895.

A self-trimming magazine lamp wherein a large number of carbons may be successively fed into operation automatically.

ELECTRIC LAMP SOCKET. H. W. Leonard, New York, 560,168. Filed June 28, 1890.

Comprises essentially two insulated conductors permanently embedded in a single piece of non-conducting moldable material, the exterior ends of the conductors being located beneath an overhanging ledge forming part of the socket.

Measurement:—

METER FOR ALTERNATING ELECTRIC CURRENTS. T. Duncan, Fort Wayne, Ind., 560,087. Filed Dec. 21, 1891.

In combination a coil traversed by the current to be measured, a revolving secondary cutting the field or fields of force generated by such coil or coils in its revolution, a magnetic path diverter, a retarding device and a registering train.

Miscellaneous:—

ELECTRIC CLOCK. B. Franklin (deceased) and D. H. Fletcher, Chicago, Ill., 559,889. Filed April 11, 1893.

The combination with a clock train, of a driving arbor, a segmental rack for actuating said driving arbor and an electrical shifting device for automatically reversing the direction of movement of said rack at predetermined intervals.

STEERING GEAR FOR SHIPS. M. Pfatischer, Philadelphia, Pa., 559,903. Filed Aug. 24, 1895.

A motor or generator armature, commutator, and adjustable brushes therefor, included in circuit with the said controlling device, a second such armature, commutator, and adjustable brushes, also included in said circuit, and mechanical connections for automatically adjusting the latter brushes simultaneously with the rudder.

ELECTRICAL STEERING GEAR. M. Pfatischer, Philadelphia, Pa., 559,904. Filed Dec. 26, 1895.

Consists in introducing into the field magnet circuit of an electric generator, a current corresponding in direction to the deviation of the controlling handle.

ELECTRIC CIGAR LIGHTER. W. Fisher, Chicago, Ill., 559,939. Filed Oct. 12, 1895.

A transparency is displayed in one or more colors each time the light is used.

THERMOSTAT. W. G. Day, Baltimore, Md., 560,023. Filed Jan. 4, 1895.

Comprises a spring in an electric circuit, and a restraining device of hard rubber, which is softened by abnormal heat.

Railways and Appliances:—

ELECTRICALLY OPERATED RAILWAY SWITCH. A. C. Goetz, Milwaukee, Wis., 559,796. Filed Aug. 24, 1893.

Means for operating switch from platform of car.

AUTOMATIC TRACK SWITCH FOR ELECTRIC RAILWAYS. W. C. Henry, Milwaukee, Wis., 559,800. Filed Dec. 20, 1893.

A trolley wire, supplemental conductors located one in advance of the other along the trolley wire, a track switch points and separate electromagnetic devices, respectively, in circuit with the said supplemental conductors and connected to operate the switch point in opposite directions.

SYSTEM OF ELECTRICAL TRANSPORTATION. P. K. Stern, St. Louis, Mo., 559,872. Filed Sept. 16, 1895.

A vehicle adapted to travel along a route, a primary inducing element arranged along the route, a laminated wheel, mounted on the vehicle and induced current conductors on said wheel.

ELECTRIC RAILWAY. J. H. Guest, Boston, Mass., 560,031. Filed Dec. 3, 1895.

The working conductor is divided into insulated sections which are progressively thrown in and out of connection with the power source by automatically actuated switch devices as the car moves along its course.

TROLLEY WIRE AND TROLLEY THEREFOR. H. R. Keithley, Buffalo, N. Y., 560,097. Filed Aug. 24, 1895.

A trolley wire having two ribs and two grooves, hangers engaging one of said grooves and both ribs, and a trolley wheel engaging both ribs and the other groove.

TROLLEY WIRE AND TROLLEY THEREFOR. H. R. Keithley, New York, 560,098. Filed March 28, 1896.

Similar to above.

Regulation:—

RUNNING COMPOUND WOUND GENERATORS IN MULTIPLE. W. B. Potter, Schenectady, N. Y., 559,907. Filed Feb. 25, 1896.

Consists of a shunt around the series circuit of each of such machines, the shunt being substantially equal in resistance to the resistance of the series coil and its adjusting resistance.

ELECTRIC REGULATOR. R. M. Hunter, Philadelphia, Pa., 560,-035. Filed May 22, 1894.

Consists in the varying of a counter electromotive force independent of that of the power motor.

Switches, Cut-Outs etc:—

ELECTRIC SWITCH. P. G. Tismer, New York, 559,916. Filed March 29, 1895.

An insulated frame for supporting the parts of a rotating arm carrying metallic plates, contact plates secured to the said frame, and a roller bearing lever for suddenly moving the rotating arm.

FUSE CUT-OUT. W. E. Harrington, Philadelphia, Pa., 560,128. Filed June 1, 1894.

Consists in providing a suitable liquid in which a part of or all of the length of the fuse is immersed.

Telegraphs:—

TELEGRAPHIC PRINTING APPARATUS. H. C. Spaulding, Boston, Mass., 559,821. Filed April 23, 1895.

Adapted for large scale printing, such as bulletins.

DISTRICT TELEGRAPH CALL BOX. W. H. Garven, Portland, Ore., 560,093. Filed June 19, 1895.

Provided with means for an answer in return from the central office, indicating that the call has received attention.

Telephones:—

ELECTRIC SWITCHING APPARATUS. W. W. Dean, St. Louis, Mo., 559,792. Filed Jan. 24, 1896.

Relates a form of spring jack and plug.

ELECTRIC TELEPHONE TRANSMITTER. N. Bassett, Philadelphia, Pa., 559,837. Filed Nov. 14, 1895.

A diaphragm, fixed terminal electrodes and movable electrode which bridges said terminal electrodes, and is in electrical contact therewith and which bears against the diaphragm.

SELECTIVE SIGNAL AND LOCKOUT SYSTEM. C. E. Scribner, Chicago, Ill., 559,869. Filed May 18, 1895.

The combination with a telephone line having at two or more substations, lockout boxes adapted to be set by current from a battery connected with the line, of a key adapted to short circuit the lockout boxes to suspend their operation.

TELEPHONE SYSTEM. W. F. Taylor, Montreal, Can., 559,874. Filed Aug. 3, 1894.

A device for closing the circuit through the terminals, which device is automatically reset when the conversation is finished and the telephone receivers hung upon their hooks.

TELEPHONE. T. Berdell, New York, 559,988. Filed March 8, 1895.

A diaphragm mounted in a magnetic field in a position of magnetic equipoise or stable equilibrium.

TELEPHONE. T. Berdell, New York, 559,989. Filed June 19, 1895.

The combination with a magnet, of two independent diaphragms, loosely held in place and adjustment by magnetic force, but out of contact with the magnet.

TELEPHONE. T. Berdell, New York, 559,990. Filed Dec. 7, 1895.

Two swinging diaphragms supported within a case of non-magnetic material between the poles of a magnet, in combination with adjustable regulating rings.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE MORGAN CONTROLLER AND REVERSING SWITCH FOR SERIES MOTORS.

The controller illustrated herewith was designed by the Morgan Engineering Company, of Alliance, O., with special reference to the requirements of their traveling cranes. The following points have been embodied in the design of the Morgan controller which tend greatly to its mechanical perfection:

The coils are of a shape to permit of their being machine wound and are compactly disposed in the frame, but in a manner which leaves them all equally open to a free circulation of air. There is a complete absence of cable connections in the interior of the frame.

The machine work on this controller, especially at the contact points, has been kept at a minimum in order to reduce the expense of renewals, thus leading to unusual facility in renewals of contact points with the least labor and loss of time possible. There are a larger number of contact points than is generally employed, which increases the fineness of the gradations in the resistance. Both the controlling and reversing of the motor is effected by the movement of one handle whose action is similar to an engine reversing lever and whose position indicates the control similar to the link-motion lever.

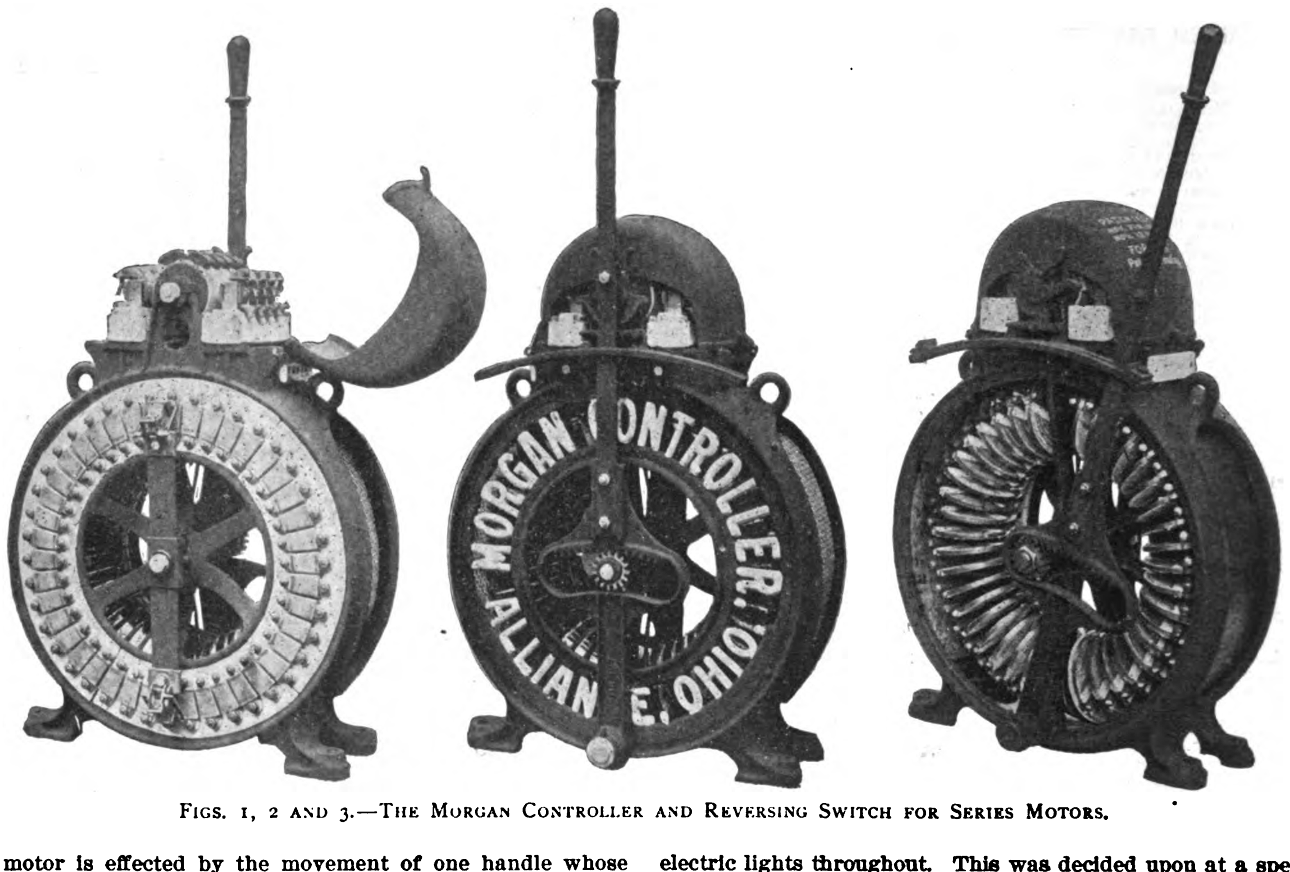
Figs. 1, 2 and 3 give a front and rear views respectively of this apparatus. Within the periphery of a circular skeleton iron frame are placed the resistance coils, the latter being wound in the shape of flat springs and lying radially within the frame. These spools are all connected in series and each alternate one is also connected with a contact piece, the circular row of which is shown in Fig. 1, and over which a contact bar is shown. The current circulates in series through the coils up to the point where the contact bar rests.

The reversing switch is mounted on top of the controller and consists of a porcelain cylinder upon which contact plates are mounted. It is shown uncovered in Fig. 1. The cylinder shaft is provided with a fork at the lever end, and a pin upon the lever engages the fork in passing the vertical position.

The contact pieces on the cylinder are easily removable and the stationary contacts on either side of the cylinder are held only by spring catches which can be loosened in an instant to replace the contacts. The ends of the reversing switch are covered with wire gauze, which, with the cover, shown open in Fig. 1 and closed in Figs. 2 and 3, completely inclose the switch. In places where metal dust and other dirt is liable to make trouble, the wire cloth is replaced by sheet metal. Fig. 3 shows the same view of the apparatus as Fig. 2, but with the back of the frame removed.

A glance at the illustrations will show how the apparatus is operated. With the lever arm vertical, as in Figs. 1 and 2, the current is cut off and the motor is stationary. When the lever is thrown forward one step the circuit is completed through the motor and the whole of the resistance coils in series, and at each successive step of the lever the coils are thrown out of circuit, two at a time, until they are all out and the motor takes the full current. By throwing the lever backward from the vertical position the direction of the motor is reversed, the resistances acting as before.

While this apparatus was designed solely for use with electric cranes, its excellent mechanical design and the simplicity of its operation have made a considerable market for it in other directions. One of its main features of excellence is the large amount of resistance which can be included.



Figs. 1, 2 and 3.—The Morgan Controller and Reversing Switch for Series Motors.

IMPORTANT CONTRACTS FOR CHICAGO WEST SIDE LIGHTING.

Parks, park thoroughfares, and boulevards in the West Town, Chicago, will in the near future be illuminated with electric lights throughout. This was decided upon at a special meeting held last week by the West Park Board of Commissioners.

Three weeks ago bids were advertised for the construction of an electric light plant and for the various articles of machinery necessary in the work. The total amount to be expended for the improvement will be over $90,000.

The following contracts were awarded:

Boilers, Standard Boiler Company, two 250 h. p., $6,300.

Condensers and Pumps, Nordberg Manufacturing Company, Milwaukee, $5,500.

Heaters, Harrison Manufacturing Company, $865.

Engines, Filer & Stowell, Milwaukee, $9,700.

Rope and drive, Dodge Manufacturing Company, $4,100.

Six 150-arc dynamos, Excelsior Electric Co., at $1,484 each.

Arc lamps, Adams-Bagnall, 750 at $22.50 each.

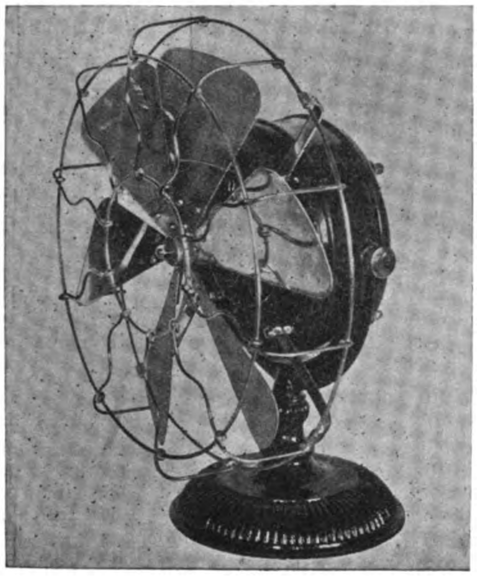
Cables, Washburn & Moen Manufacturing Company, 7½ and 11 3-16 cents a foot.

Switchboard, Western Electric Company, $1,250.

Pulley block and crane, Whiting Foundry Equip. Co., $1,225.

THE G. E. '96 ALTERNATING FAN MOTOR.

THE '96 model alternating current fan motor of the General Electric Company embodies a number of improvements dictated by careful observation of the performances of the fan motors of previous years. Of these improvements, perhaps the most important is the universality of direction which can be given to the draft caused by the revolving blades. The motor field frame being provided with trunnions resting on a yoke, the current of air may be directed at almost any single in a vertical plane, while the yoke is so set in the base that the motor may be moved through a complete circle horizontally and the current be directed toward any point desired. The yoke may also be removed from the base and inserted in a wall bracket. The design of the motor is both simple and ingenious. The field is a ring built up of thin iron punchings with



THE G. E., '96, ALTERNATING FAN MOTOR.

inwardly projecting teeth carrying the field wiring. The armature is a cylinder of iron laminations, with small bare copper rods running through the iron and terminating in copper discs fastened at the end of the core.

There are neither brushes nor commutators, and, in fact, this small fan motor embodies principles similar to those involved in the large General Electric induction motors.

To reduce the friction of the starting and running current the fan is provided with smooth running bearings with hardened steel cones and balls. No oil is required to lubricate this bearing, and as none can be thrown off one of the great drawbacks inherent in fan motor bearings is eliminated. The diameter of the fan is 12 inches and the speed 1,800 revolutions per minute.

TEST OF THE MOYES "COMBINE" WATER TUBE BOILER.

MR. JAY M. WHITHAM, consulting mechanical engineer, of Philadelphia, recently concluded a test on the Moyes "Combine" water tube boiler, at the power station of the Marietta, Pa., Electric Light, Heat and Power Company. The object of the trial was solely to determine the boiler capacity, which was rated at 125 horse-power, based on the evaporation of 30 pounds of water per hour from a feed-water temperature of 100 deg. F. into steam at 70 pounds pressure.

In conducting the test the coal and water were weighed, height of water in boiler noted, and depth of fire at the beginning and end of the test was measured. The test was made during a run of 8.65 hours, and in this time the horse-power developed by the boilers varied between the minimum, 138 horse-power, and the maximum, 179 horse-power, the average for the 8.65 hours run being 161.4 horse-power.

Mr. W. Barnet Le Van, the well-known mechanical engineer, co-operated in the tests as representative of the company. We give below the results of the tests and conclusions:

Moisture in coal	2%
Ash and refuse in coal	11.13%
Moisture in steam by the Barrus calorimeter	0.13 of 1%

(Mr. Le Van says that a steam having 3 per cent. moisture is practically dry, hence 0.13 of 1 per cent. must be very satisfactory to him.)

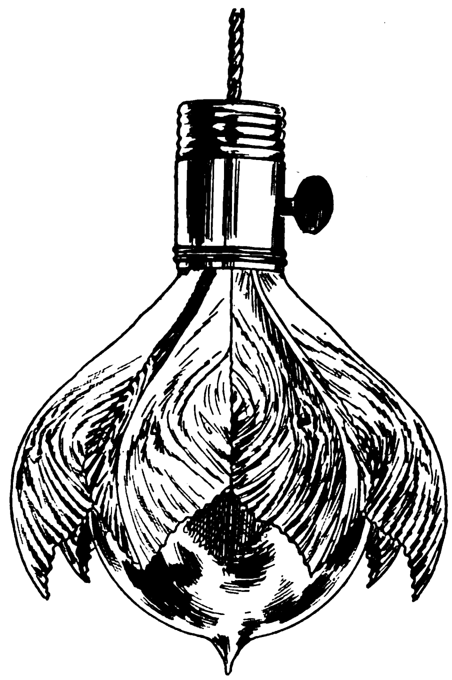
Water evaporated from and at 212 deg. F., per lb of dry coal	9.346 lbs.
Water evaporated from and at 212 deg. F., per lb of combustible	10.52 lbs.
Boiler horse-power actually developed, by basis of 30 lbs. per hour from 100 deg. F., at 70 lbs. pressure, average for 8.65 hours	161.4
Rated boiler horse-power	125
Horse-power developed above rating	29.1%
Pounds of dry coal burned per hour per boiler horse-power developed	3.69
Pounds of wet coal burned per hour per boiler horse-power developed	3.75

CONCLUSIONS.

1. The boiler steams freely and with ease.
2. The steam is remarkably free from moisture, being practically dry.
3. The water level is very steady, not vibrating, under the conditions of working this test, over one inch.
4. The walls of the boiler setting are covered with a plaster of non-conducting material, and were colder than any walls ever noted by the writer. This retention of heat in the setting is conducive to economy.
5. The distribution of the draft in the various passes of the gases was as follows: Draft at stack base, 0.514 inch; second pass, 0.445 inch; top of first pass, 0.394 inch; furnace, 0.242 inch. This shows a skillful proportioning of the flue areas.
6. The fuel burned having over 11 per cent. ash, was not as good as an average quality of Clearfield coal. I have made scores of trials of this coal, covering periods ranging from 8 hours to 6 months, and find that the Clearfield coal usually found in this market has from 4 to 8 per cent. ash, and seldom as high as 10 per cent.
7. The boiler developed with ease 29 per cent. excess capacity above its rating, and with good economy.
8. Mr. Le Van and I are both of the opinion that this boiler, run at its rating, will show about 10 per cent. better economic results. This means that, whereas 3.69 pounds of dry coal an hour were used per boiler horse-power at 29 per cent. excess capacity, only about 3.35 pounds would be required at its rating.
9. The boiler is well suited to supply steam for a steady pull, and also to respond to sudden fluctuations in the demand.

THE McCREARY PAPER LAMP SHADES.

WE illustrate herewith the "Novelty Lamp Shades" that are being introduced by Mr. A. A. McCreary, 136 Liberty street, this city. They are intended for temporary ornamental decoration, and answer that purpose admirably;



THE McCREARY "NOVELTY" SHADE.

while they are also of utilitarian value, as a means of protecting the bulb from dust, dirt, etc. The paper shades are artistically crimped, and fit the bulb in such a way as to make it seem like the heart of a big lily. A set will be sent to any

address by the vendors, on receipt of 35 cents. Such shades should find a wide application, especially in summer time. They are made in white and eight colors.

THE EMERSON ELECTRIC MFG. CO.

We have received the 1896 catalogue of the Emerson Electric Manufacturing Company, of St. Louis, Mo., containing descriptions and illustrations of their alternating current motors for fan and power purposes. Their list of fans is very varied. Among their specialties for the season are their 16-inch fan motor for both 16,000 alternation systems and 7,200 alternation systems, and their "Emerson" power motor. This machine, giving an efficiency of 65 to 80 per cent., may be run on one side of two or three-phase systems with only one transformer. It is non-synchronous, and has speed regulations within 5 per cent. Its starting power is 50 per cent. in excess of rated power, and its running power is 50 per cent. in excess of rated capacity. The firm construct special motors for sewing machines, dental and other work.

KOCH WOVEN WIRE BRUSHES.

Messrs. Goldmark & Wallace, 29 Chambers street, City, are selling agents for J. C. Koch, Hohenlunburg, Germany, manufacturers of the celebrated woven wire tube dynamo brushes. These brushes are the result of numerous practical trials and experiments. The mesh of this brush is composed of finely drawn pure electrolytic copper wire, diagonally woven, which is surrounded by a mantle of copper wire woven like lace. The two weavings are connected with small aluminum tubes, making the brush very porous. The tubes also increase the elasticity of the brushes and permit them, if desired, to be used entirely without guards, or with guards drawn well away from the bearing end of the brushes.

These brushes do not cut the commutator. No filing is required to keep them in shape and they are quite noiseless.

Messrs. Goldmark & Wallace will be pleased to send a set of these brushes on trial on information as to the size required.

BIDS WANTED AT ONCE.

The Port Clinton Electric Light and Power Company, of Port Clinton, O., will receive bids for boilers, engines, dynamos, etc., for an electric light and power plant, up to noon on Thursday, May 28, 1896. Specifications are on file with C. I. York, secretary.

BIDS WANTED FOR LOUISIANA, MO.

The present contract for lighting the streets of Louisiana, Mo. (a city of about 6,000 people, 100 miles north of St. Louis, on the Mississippi River), will expire about October 1, at which time, or before, the city council will probably make arrangements for a plant operated under city control, make a contract with the present company, or accept a bid from some other party. Louisiana is peculiarly located for the erection of a plant very economically, owing to the city not being scattered. The mayor is Henry L. Hart, to whom all inquiries should be mailed.

THE WEBSTER VACUUM SYSTEM OF STEAM HEATING.

Warren, Webster & Co., of Camden, N. J., have issued an illustrated catalogue describing their system of heating feed water for boilers, and also of warming buildings within a radius of 2,000 feet from a power house, by utilization of exhaust steam, without causing back pressure upon the engines. The vacuum system of steam heating has been extensively adopted and is generally familiar to steam users in the United States. The present catalogue considers a refinement of the system as heretofore applied, whereby thorough control, as well as more economical and efficient use of exhaust or live steam is secured for either heating or drying purposes. The system is rendered self-controlling by means of thermostatic water and air relief valves, which are fully described in the catalogue.

THE FASHIONING OF A LAMP.

Under the above title the Bryan-Marsh Company, 136 Liberty street, New York, have issued a pamphlet descriptive of the methods employed in the manufacture of incandescent lamps at the company's factory at Marlborough, Mass. Supplementing this description is an illustrated catalogue of the numerous styles of incandescent lamps manufactured by this company, ranging from a one-quarter to a three-hundred candle-power lamp for all purposes.

They are made in all varieties of sizes, shapes and colors suitable for ornamental and decorative lighting of all kinds, and considerable attention is given to high efficiency battery lamps which are made for bicycle, dental, kinetoscope and other special uses.

THE ELECTRICAL EQUIPMENT FOR BROOKLYN BRIDGE.

The trustees of the New York and Brooklyn Bridge, at their meeting last week awarded contracts for the new electrical plant for the bridge, as follows: For twenty passenger cars, provided with electric motors, to the Pullman Palace Car Company, at $3,200 each; for two electric generators, to Walker Manufacturing Company, at $15,849; for two six hundred horsepower engines, to the Southwark Foundry and Machine Company, at $16,400; for two boilers, of a combined 400 horsepower, to the Babcock & Wilcox Company, at $4,350, the highest bid received.

THE C. W. HUNT CO.'S ROPE TRANSMISSION.

"Manila Rope" is the title of an instructive catalogue published by The C. W. Hunt Company, of New York, which contains a brief treatise for engineers on ropes used for the transmission of power, together with formulæ, tables and data useful in mill engineering. For transmission purposes the company makes a specialty of a selected manila fiber, known under the trade name of "Stevedore." Two kinds of rope are made from this; one spliced endless for running over large sheaves, and the other for use with the usual pulley blocks of from 8 to 16 inches diameter. A plumbago lubricant is used in laying up this rope which reduces the internal friction of the fibers on each other in bending over the pulleys and also renders the rope nearly waterproof, so that but very little moisture is absorbed even in a heavy rain in an outdoor transmission.

NEW YORK NOTES.

W. R. OSTRANDER & COMPANY are now occupying their new quarters at 22 Dey street, with increased facilities for carrying on their large business in bells, annunciators, push-buttons, etc. In addition to the above, their stock of electric light supplies is replete with all that is newest and best.

H. B. COHO & COMPANY, of New York, have just issued a neat little brochure, giving an illustrated description of the various goods which they represent. First are shown some illustrations of the Eddy dynamos, motors and platers; then the Royal alternator and transformer. Following these are illustrations and price lists of the Horton voltmeters, Crown woven wire brushes, Peerless soldering stick and commutator compound, theatre dimmers, rheostats, fan motors, and fiber-graphite commutator brushes. A page is also devoted to the Bradley gas generator. Altogether the little book is useful to every manager of a central station or isolated plant.

THE INTERNATIONAL ELECTRIC COMPANY, 76 Beekman street, New York, have just completed a large induction coil which is to be used especially in X-ray work. Mounted on its base it stands 23 inches high; the base measurements being 23 x 43 inches, while the coil itself is 23 inches long with a diameter of 13½ inches. The primary is made of No. 5 wire in two layers of 153 turns each, with a diameter of 3 inches, while the secondary is of No. 36 wire, of which it has been estimated about 70 miles were used in the construction. The spark length is 12 inches. It is hansomely mounted according to the style adopted by this company in finishing their instruments.

WESTERN NOTES.

THE AKRON SMOKING PIPE COMPANY, manufacturers of the Fenton porcelain insulating tubes, cleats and knobs, have removed their general office to Mogadore, Ohio.

THE ELECTRIC APPLIANCE COMPANY have succeeded in producing, with a few slight changes from the regular Upton arc lamp, a lamp that will burn 30 hours with a single pair of carbons. This lamp is meeting with much favor and will probably largely displace the regular 10, 12 and 15 hour lamps. In addition to its great convenience, the question of its greater economy is a point which cannot be overlooked.

NEW ENGLAND NOTES.

THE W. S. HILL ELECTRIC COMPANY have made a change, having organized a new company under the laws of Massachusetts with $70,000 capital. With their new and commodious factory, they will be in a better position than ever before to handle their business.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. JUNE 3, 1896. No. 422.

ELECTRIC TRANSPORTATION.

THE BERGEN COUNTY TRACTION COMPANY'S SYSTEM.

THE west bank of the Hudson River opposite the upper part of New York City presents one of the most difficult obstacles to street railway travel that could well be found; as for several miles south from the Palisades the continuation of this range of cliffs is so little removed from the vertical that an elevator seems more feasible than a trolley car in reaching the summit of the range. In fact, elevators were adopted some time ago by the West Shore Railroad at the terminus of the Forty-second street ferry from New York for making this ascent, and later a street railway line was attempted at Fort Lee. The latter had to be abandoned, as the grades were found impracticable at that point. The Bergen County Traction Company, however, found a practical spot for crossing the cliffs at Pleasant Valley, about a mile south of Fort Lee. The road over the mountain was then constructed, having for its terminus Pleasant Valley at the Hudson River end and Englewood at its western end. The right of way is being secured for a branch road to Hackensack, the county seat of Bergen County, and the company's charter provides for a number of other branches covering a considerable area in Bergen County. The ferry formerly running from 130th street, New York, to Fort Lee, was purchased by this company, and the New Jersey terminus was moved down to Pleasant Valley, directly in front of the company's power house on the shore. Fig. 1 gives a view of the new ferry slip and power-house, taken from the river, and Fig. 2 shows the New York terminus of the ferry, which is close to the Grant Monument in Riverside Park.

THE POWER HOUSE.

The power house, shown in Fig. 3, is a commodious building 111 feet 4 inches by 74 feet 4 inches, built on the side hill some 200 feet back from the river. The building is built of hard burned red brick laid with red mortar, the trimmings being of Pennsylvania bluestone. The roof is slate and supported on Berlin Iron Bridge Company's trusses, which span from the partition wall between the boiler room and engine room to the outer walls of the building. Both the engine room and boiler room are lighted on three sides with very large windows with double sashes, which will be seen in the illustrations, and between the windows pilasters are built into the side walls, giving the building an appearance of massiveness. Monitor ventilators are used upon the roofs of both rooms, and the whole of the lighting and ventilating appointments make the building unusually comfortable in these respects. The construction of the buildings was done by J. W. Ferguson, of Paterson, N. J. The general plan of the building and the location of the machinery will be seen in the diagram, Fig. 4.

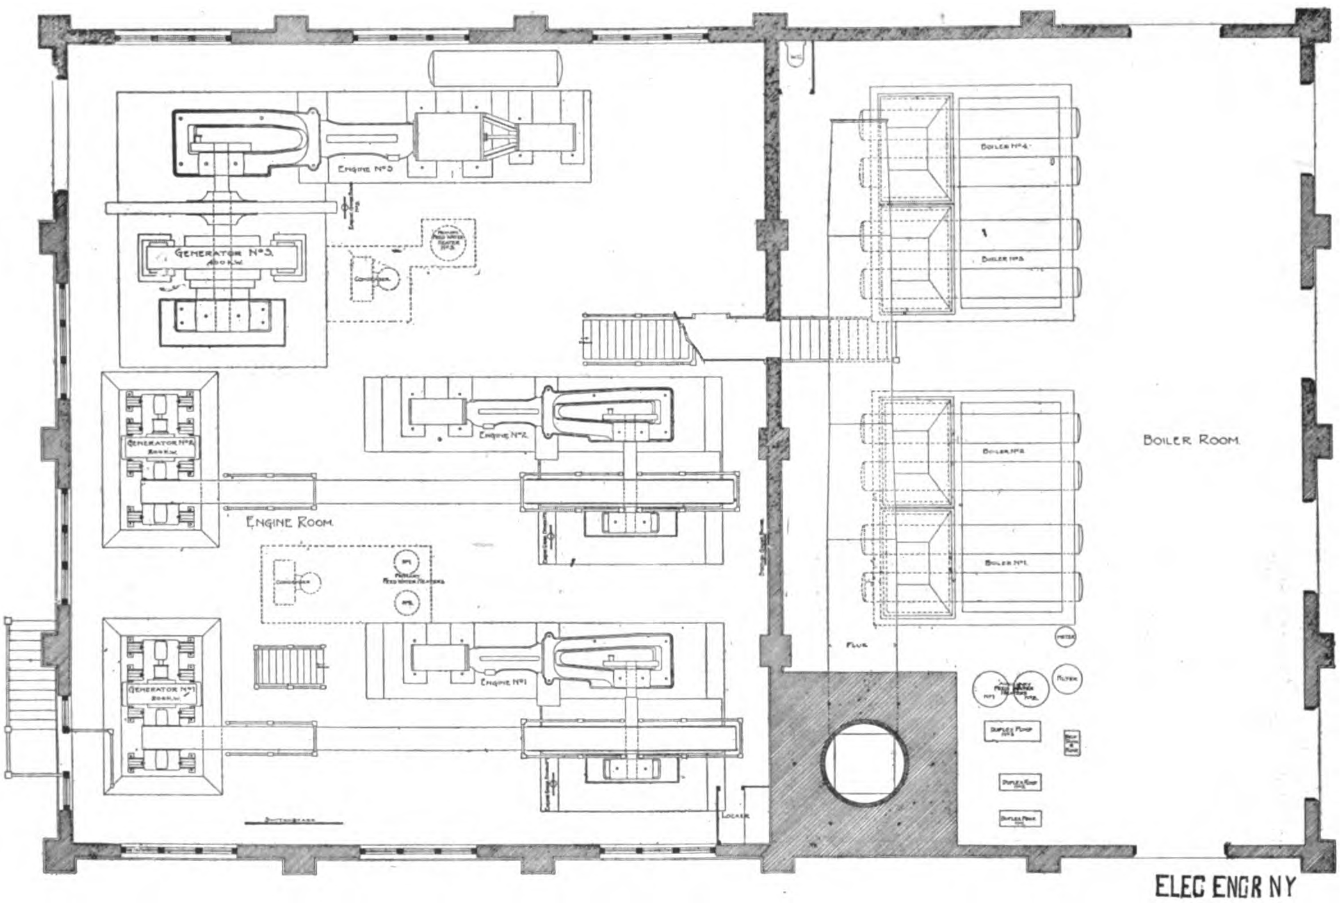


FIG. 4.—PLAN OF ENGINE, DYNAMO AND BOILER ARRANGEMENT, BERGEN CO. TRACTION CO.—FORD & BACON, ENGINEERS.

ENGINE ROOM.

The engine room occupies the southern end of the power house, and is handsomely finished and painted throughout. The equipment of the engine room is divided into two equal units, which are exact duplicates of each other, and provision has been made for a third unit, which will be equal to both of those already installed. The capacity of the plant can therefore be

Fig. 1.—View of Power House from River.

doubled without making any alterations on the building. The two engines now installed are single cylinder, of the Allis-Corliss type and will be seen in Fig. 5. The cylinders are 20 inches by 42 inches, and each engine is belted directly to a 200-kilowatt General Electric multipolar generator. The engines are run either condensing or non-condensing, according to the load on the line, and at a speed of 80 revolutions per minute. Two separate eccentrics are used on these engines, which permit the steam to follow ⅞ of the stroke, if necessary, on overload. The generators are placed behind the cylinders of the engines, and the belts, supplied by the Page Belting Company, run below the floor, in a basement, where the piping is situated. Fig. 6 shows a view of the generators. The switch-

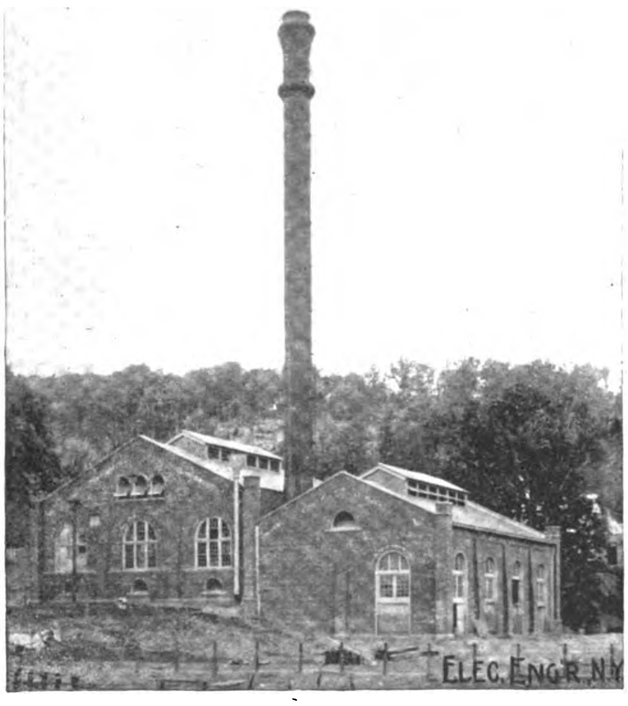

Fig. 3.—Power House, Bergen County Traction Co.

board, the location of which is shown on the plan, Fig. 4, is the standard black enamel slate board of the General Electric Company, and contains three panels. Two of these are for the two generators and contain Weston ammeters and voltmeters, and General Electric automatic cut-outs, resistance boxes and lightning arresters. The third panel contains switches and instruments for the four feeders to the line. Space at either end of the board is allowed for the addition of extra generator or feeder panels. The station gauge board is somewhat novel in being made of enameled slate instead of wood, as ordinarily seen. Its trimmings are of nickel and it contains an eight-day clock, a Crosby recording steam gauge, and a vacuum gauge. In the center of the board a nickel nameplate contains the name of Ford & Bacon, the mechanical and electrical engineers, by whom the plant was designed. The only other apparatus seen in the engine room is the Spencer damper regulator water column and the valve stands, which are brought

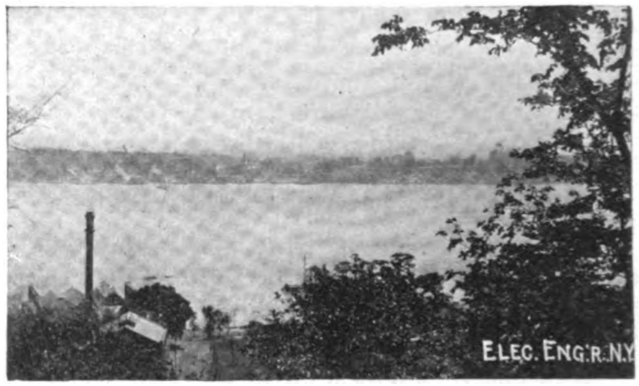

Fig. 2.—A Glimpse of New York from the Palisades.

through the floor. Absolutely no piping whatever is seen in the engine room, it being all contained in a basement below the engines. The piping is all supported on separate special foundations of its own.

All the machines in the engine room are painted in royal blue with gilt striping, and, together with the neat finish of the building itself, make a particularly neat and attractive room. The night lighting is supplied by two arc and twenty incandescent lamps, the latter being distributed around the side walls.

BOILER AND PUMP ROOM.

The boiler room, separated from the engine room by a heavy partition wall, is 7½ feet below the basement level of the latter, which makes it nearly on a level with the water front, where the coal is landed. This room contains in one side two 250-horse-power Heine safety boilers, which are now run at 100 lbs. pressure, and have been tested up to 165 lbs. These boilers occupy only half the available floor space in the boiler room, which will permit of its capacity being doubled, corresponding to the engine room extension. Figs. 7 and 8 give views of the boiler and pump room. To the right of the boilers are installed two Geo. F. Blake M'f'g. Co.'s boiler

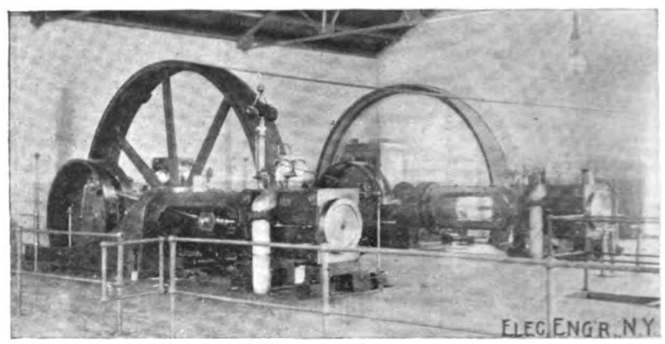

Fig. 5.—View of Engines in Power House.

feed pumps, one drip tank and one Goubert feed water heater. The stack rises from the back of the boilers at the partition wall of the building. This is of steel and is self-supporting. It rises to a height of 140 feet and is 6 feet 6 inches in diameter. This height is, under usual circumstances, considerably greater than would be necessary for this size of plant, but fearing that its position directly under the cliff would affect the draught, it was made higher than usual for its capacity. The stack was furnished and mounted by the Warden Manufacturing Company, of Philadelphia.

The piping on the live steam side of the system is all in duplicate, from the boiler outlet to the steam engine throttle valve. The duplication is not done, however, in the usual way, by having two pipes, each of the full capacity required, but by a method devised by Mr. George H. Davis, a member of the firm of Ford & Bacon. In the Davis system the combined area of the two pipes equals the area that would be required for a single pipe of the usual system, and both the small pipes are in use all the time. If an accident occurs to either pipe it is shut

down and the other one is forced during the short time necessary to make the repairs. This system of double piping, which has been found to answer all the requirements for which the full size duplicate pipes are installed, costs but little more than the single large piping system, and, of course, far less than a large pipe duplicate system. The pipe fitting was done by Benjamin F. Shaw & Co., and the pipe covering by the H. W. Johns Manufacturing Company. The piping connections to and from the engines are all made in a basement specially designed for that purpose. After passing to the separators the steam pipes rise vertically through the floor to the lower side of the steam chests of the engines. The exhaust similarly passes vertically through the floor down to the basement, where the piping is arranged so that the steam can exhaust directly into the atmosphere, or by closing this and opening another branch the steam is carried to a Blake twin upright jet condenser. The valve stands, shown on the plan (Fig. 4) of the engine room, indicate the location of the gate valves in the exhaust, the condenser and the air pump, which are directly underneath the engine room floor.

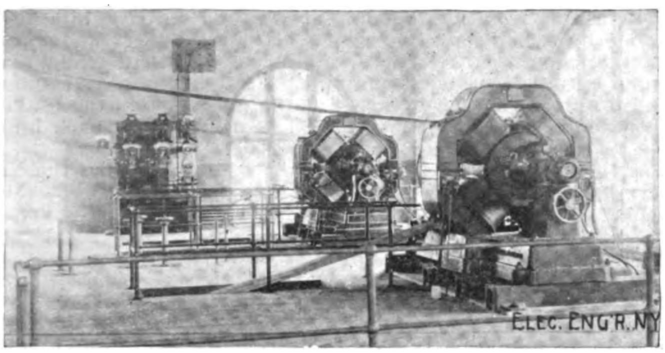

FIG. 6.—VIEW OF DYNAMOS AND SWITCHBOARD IN POWER HOUSE.

LINE AND TRACK CONSTRUCTION.

The part of the line which presented the greatest difficulty to the engineers was the first mile after leaving the ferry. Here the road starts off with a grade of 8 per cent., which extends for a considerable distance in a nearly westerly direction until the first loop approach is reached, showed in Fig. 9, which curves around the company's water storage reservoir, from which the water for the boiler supply is secured for about nine months in the year. Here the grade drops to 6½ per cent. and the road takes a southerly direction for about a quarter of a mile. At this point a safety switchback is built, and the car passes back in a northern direction to a second loop approach, where it again resumes its general westerly direction. The grade is uniformly 6½ per cent. from the lowest loop approach to the top of the mountain.

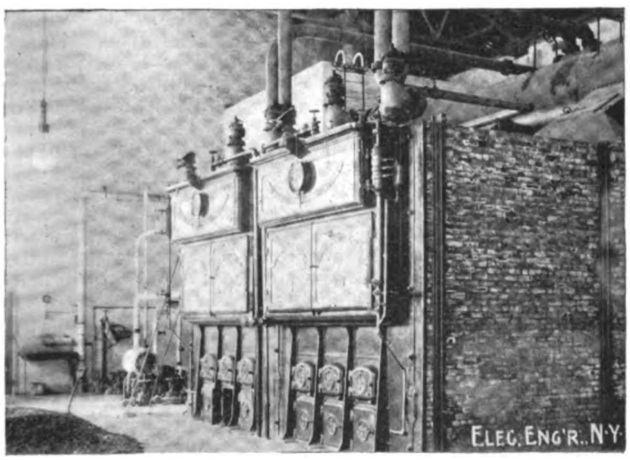

FIG. 7.—BOILER ROOM, BERGEN COUNTY TRACTION CO.

The rails throughout are 60-lb. T, and are laid on cross-ties. The rails were furnished by the Pennsylvania Steel Company and the track was built by Kearns & Egan, the special track work being done by the Wharton Switch Company. The downgrade side of the safety switchback is continued by a reverse grade which would stop a car, even if the brakes should fail to work properly. In passing from one side of the switchback to the other track automatic spring switches are used which do not require any manipulation while running over them in either direction. The entire road along the side of the cliff had to be blasted out of solid rock and at short intervals retaining walls have been built on the outside edge of the road. All of this part of the road is ballasted with broken stone obtained from the cuttings.

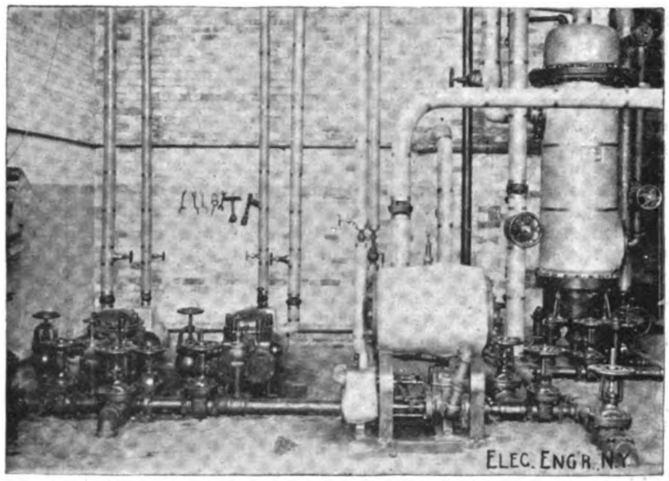

FIG. 8.—PUMP ROOM IN POWER HOUSE.

FIG. 9.—A LOOP AT THE FOOT OF THE PALISADES.

The overhead construction on this part of the line is entirely side bracket construction, the poles for which are set in the solid rock. In some places the poles for guy wires and the pull-off wires for the loop approaches are 60 feet in height because of the steep slopes at certain points. The trolley line between Pleasant Valley and Englewood is fed by feeders, for which a separate pole line is run down the side of the cliff to

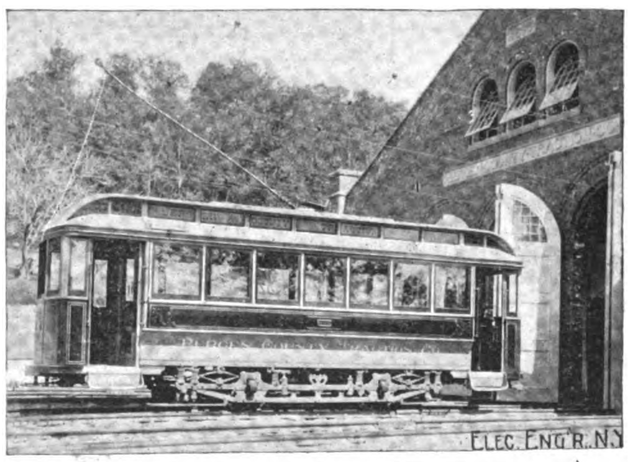

FIG. 10.—VESTIBULE CAR, BERGEN COUNTY TRACTION CO.

save the length of copper wire caused by the detours of the line in ascending the cliff. In some places the separate feeder line runs nearly vertical down the face of the cliff. The road is a single track construction with turnouts. This construction was done by the White Crosby Company, and was one of the greatest difficulty, as well as of the finest workmanship.

THE CARS AND CAR HOUSE.

The car house, a portion of which is shown in Fig. 10, is situated about 100 feet west of the power house and is of the same style of architecture as the latter. It is 104 feet 4 inches in length and 74 feet 4 inches wide. It contains five tracks, and car pits are built under the three right hand tracks. The building is entirely open inside except at the corner, shown in the illustration, where an office and work room are partitioned off for the use of the employés of the road.

The cars are handsomely finished and are fitted up in dark wood, with bronze trimmings. They are vestibuled on both ends and are 20 feet long inside, with an 8-foot wheel base. They have General Electric equipments, consisting of two 1,200 motors, each capable of developing 40 horse-power. The car bodies were built by the St. Louis Car Company and by the Jackson & Sharpe Company, and are lighted by ten incandescent lamps, nine inside and one outside of each car. The brakes and fare registers were manufactured by the Stirling Supply Company.

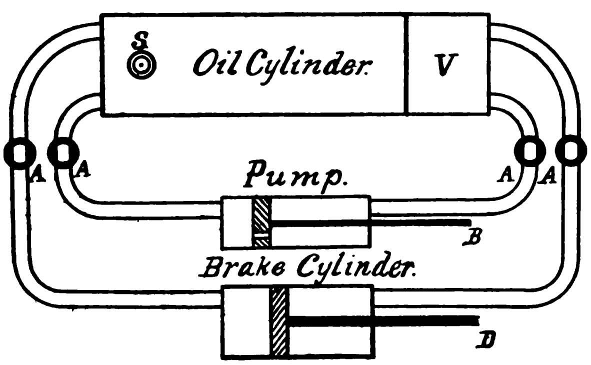
The officers of the Bergen County Traction Company are: President, Jacob E. Ridgeway; vice-president, W. H. Clark; secretary and treasurer, W. N. Barrows, and superintendent, E. W. Lawson.

The mechanical and electrical engineering work was done by Ford & Bacon and the civil engineering work by Wm. Hunter. The engineering work presented many difficulties which have been ably overcome, and the road in every respect is a model of excellent engineering skill.

A NEW HYDRAULIC BRAKE FOR STREET CARS.

ON Tuesday afternoon, May 26, an exhibition of a new hydraulic brake was given in Brooklyn on one of the cars of the Brooklyn City Railroad Company. Car No. 3701, of the Myrtle and Gates avenue division, was fitted up with the new brake manufactured by the Lombard Hydraulic Brake Company, 51 Hampshire street, Boston, and through the courtesy of Mr. G. W. Goodwin, division superintendent, a number of street railway engineers made the trip from Fulton Ferry to Richmond Hill and back to test the operation of the brake.

A general idea of the mechanism is shown by the accompany-



ARRANGEMENT OF LOMBARD HYDRAULIC STREET CAR BRAKE.

ing diagrammatic illustration. The large cylinder shown on top is divided into two separate compartments, one of which contains oil at a pressure of about 220 lbs., which may vary somewhat with the grades to be traveled and the frequency with which the brake is to be used. There are two pipe connections at each end of these cylinders, as shown, one set connecting the oil chamber and vacuum chamber, V, through the pump, whose piston rod, B, is geared to the car axle, and the other pair of pipes connecting the same cylinders through the brake cylinder, whose piston rod acts directly on the brake beam. A safety valve, S, is placed upon the oil cylinder in case the pressure of oil should become too great. It consists of a flat cylindrical box, whose outer face is made of a thin disc of metal perforated by a pinhole at the center. Behind this hole a screw presses just hard enough to prevent the oil escaping when at its maximum pressure, but if the pressure should rise above the point for which the gauge is set, the front disc is pressed out and allows some of the oil to escape, thus reducing the pressure. The operation is as follows: A valve is opened to the outside air, which is pumped into the oil cylinder until the required pressure is obtained, when the valve is closed. The valves AAAA in practice are combined into one four-way valve, and when this is opened the pressure from the oil cylinder is transmitted to the brake cylinder piston, which moves forward and actuates the brake beam according to the amount of oil admitted behind it. The important feature of this admission valve is that it allows the oil to pass when the hand lever is moved and shuts it off when the lever stops, in no matter what position in its range. Thus a movement of an inch on the hand lever puts a slight pressure on the wheels, which remains constant while the lever keeps its position, and is increased if the lever is turned forward; but if it is turned off, the oil escapes from the brake cylinder into the vacuum by an outside port, not shown, and from the vacuum it falls by gravity into the pump, by which it is returned to the oil cylinders under its original pressure. It will therefore be seen that, while the pump is running constantly, its piston is moving in a vacuum and it absorbs no power except at the moment that the brake is turned off, when it pumps the oil used in braking back into the oil tank.

As the brake is used and released, it will be seen that the oil travels in a closed circuit from the oil cylinder to the brake cylinder, then to the vacuum chamber, from there to the pump, and, lastly, back to the oil cylinder, into which it is forced at its original pressure. The entire operation is controlled by the movement of one hand lever, and the brake is designed to be used constantly, not as an emergency brake. It is attached at the same point of the brake beam that the ordinary hand brake is fastened, and the use of one is entirely independent and does not interfere with the use of the other.

On the return trip several trials were made to test the efficiency of the brake in making quick stops. With a 32-foot car running at about 22 miles per hour the stop was made in two car lengths from the place the brake was applied. At 17 miles per hour, the same car was stopped in 36 feet, while at the ordinary rate of 8 or 9 miles per hour, the car was easily stopped within 6 or 8 feet.

POWER TRANSMISSION.

ELECTRICAL PLANT OF THE SILVER LAKE MINES.

A FEW months ago we described the interesting power transmission plant installed by the General Electric Company at the Silver Lake Mines of Mr. E. G. Stoiber, at Silverton, Col. The introduction of electricity into the operation of the mines has resulted in economy so noticeable that an increase in the plant is now being made to provide for an extension of the system in the mines and to reinforce the water power, which is not sufficient to furnish all the power required throughout the year.

Two cross compound Corliss engines, with cylinders 24 x 46 x 48 inches, each engine of 850 indicated horse-power, are now being set up, together with water tube boilers, mechanical stokers, coal and ash conveyors, feed water heaters, separators, water meter and coal weighers, the whole making what will be the most thoroughly modern steam plant in the State.

The difference between the cost of coal at the power house and its cost at the mine, which is at greater elevation by some 2,500 feet, is such that the saving effected, even when steam power is used for generating purposes, will insure an ample return on the investment, while the economy induced by the use of the water power is considerably greater. Mr. Stoiber, therefore, feels that in adopting electricity for the operation of his mines he has greatly diminished the cost of working them.

The present plant now in operation consists of two 150 kilowatt, three-phase, water driven generators, supplying current to one 100 horse-power motor for the mill, one 100 horse-power motor for the air compressor, one 75 horse-power motor for the hoist, one 15 horse-power motor for the pump, one of 1 horse-power for a blower and to incandescent lights scattered throughout the station, mill and mine. The additional plant will consist of two 150 kilowatt generators, one 100 horse-power motor for the mill; one 15 horse-power motor to drive a pump, and two of 10 horse-power for blowers, forges and miscellaneous machinery. To eventually utilize to the full the capacity of the steam and water power plants additional and larger generators will be set up.

Not the least interesting feature of this installation is that, although the entire output of electrical energy is to be used in the operation of a single mining property, it will be, when completed, the largest electric power plant in the State of Colorado.

ELECTRIC LIGHTING.

CHARGING FOR ELECTRIC LIGHTING SERVICE.

BY ARTHUR J. FARNSWORTH.

IT is rather curious that in so extensive and carefully developed an industry as electric lighting the usual methods of charging customers remain so crude and inaccurate. Even in the largest companies the system is apt to be far from perfect, and there is little doubt that customers are sometimes supplied with current at an actual loss. In the smaller companies, located in country towns, this unsatisfactory and unjust condition almost always obtains in an exaggerated degree. The problem undoubtedly is a difficult one, but it would appear that in many cases the fundamental principles and the features that a desirable system should possess are not fully understood. The writer wishes to make a simple exposition of these principles, to note the defects in the common methods, and to call attention particularly to a system in which some of these defects have been removed.

The subject has not been without attention, and several methods, excellent as partial solutions of the problem, have been suggested, as well as a multitude of mathematical formulas. The latter have for the most part tended to increase the confusion and uncertainty that already existed, and their use is to be discouraged. The condition of no two stations will be exactly alike, and even if it were possible to deduce equations for the various cases that occur, they would be so complicated, and take so much time in their application, as to become practically useless. Mathematical accuracy is by no means the only or even the most important consideration. A system to be successful must be simple and popular, as well as precise, and have a tendency to promote current consumption. None of the present methods appears to perfectly fulfill these requirements.

All operating expenses may be divided into three distinct classes, based upon the manner in which they should be portioned among the customers.

Class A will contain those items which should be shared equally by each customer, irrespective of size, because the benefit to each is the same.

Class B will contain expenses which should be divided among the customers proportionally to the size of their equipment.

Class C will be the remaining operating expenses, all of which are some function of the customers' current consumption.

As an illustration, in a small alternating current station, the operating expenses might be classified as follows:

Class A.—All office expenses, including stationery, stamps, advertising, telephone, heating and lighting, clerical service, etc. Also meter reading and repairs, stable expenses, and all salaries and wages, except those that are only paid during part of the time when the load is unusually heavy.

Class B.—Interest on the total investment, depreciation, taxes and insurance on all property owned by the company, except stables, which are provided for in Class A. Also municipal concessions, energy wasted in transformer core loss, extra labor necessary during heavy load and a contingency fund to cover legal and incidental expenses.

Class C.—Coal, oil, waste, water tax, ash removals, loss of energy in transmission lines, boiler, engine, and dynamo repairs, engine room supplies, etc., and all operating expenses which are any function of the load.

It will be noticed that the items in Class A are in no way affected by the equipment or consumption, and are made necessary by the mere existence of consumers as such. All consumers, therefore, since the benefit to each is the same, should contribute the same amount towards the defrayal of these expenses. The items of the second class will depend in amount upon the capacity of the station, and since it is correct to assume that each individual equipment is suitable for its average load, this class of expenses should be divided among the consumers proportionally to their equipment. The items specified in Class C, of course, imply that in the station under consideration several units are in use, the number at any time depending more or less upon the load.

This tabulated statement, as given, may not be entirely correct, and the classification may vary considerably with circumstances. Some items might perhaps properly belong to more than one class, and for the disposition of such the manager must rely upon his judgment. It is not intended to discuss this question here, and the table is given merely as an illustration of the general principles of classifying operating expenses according to the manner in which they affect the cost of supplying customers.

The greater part of the difficulty of determining the cost of supplying current lies in fixing the relation of the various Class C items to the station output. As the efficiency of the generating plant is constantly changing with the load, it will cost more to produce a kilowatt hour at one time than at another, and this variation should be determined and allowed for if possible. The several factors are numerous and incalculable to any accurate degree. The only practical method will be to obtain actual, running data, extending over a considerable period of time and covering as many conditions as possible. For instance, the coal may vary considerably in quality. One fireman may do better than the next, or perhaps during portions of the year it will be advisable to run condensing and at other times non-condensing. What is desired is the knowledge how much a kilowatt hour is costing at any hour of any day in the year, and with a little care and patience data sufficiently accurate can be obtained.

Knowing that the cost of supplying a customer with current will depend somewhat upon the time at which it is produced and very largely upon the amount, how shall it be sold? Two excellent methods of charging different rates for current at different portions of the day, and which may be included in any general system of charge, have been suggested by Messrs. Wright and Kapp. It is therefore not necessary to dwell upon this point in selecting the best general system. The problem is, What is the best general method; one that shall be at once just, simple, popular and tend to promote consumption? It must be capable of showing the minimum annual charge at which it will pay to accept a customer and make it equally profitable to supply a given amount of current to a number of small consumers as to one large one.

The system commonly used in small stations of charging a fixed amount per kilowatt hour under all circumstances is highly improper. It is these stations which operate under the greatest extremes, and this system, if it is to be used at all, should only be used by such of the larger companies as have a nearly constant load. During a customer's absence, which may last months, it will take no account whatever of his A and B expenses, although they continue to go on, and it will be some time after his return before this loss is made up. It also leads to a false idea in regard to soliciting new business among small consumers, and as it gives no clue as to where the line should be drawn, it will almost invariably result in the company supplying a class of customers that cannot prove anything but a continual source of loss. Another objectionable feature of this system is that it tends to decrease rather than promote consumption, for the reason that the benefits are all in favor of the small consumer. The result of this, of course, will be to encourage and increase business among the most undesirable or even dangerous class, and to prevent much consumption upon a large scale, because of the enormous charges. As a matter of fact, when this system is used discounts are almost always made to the largest consumers, but it is easy to distinguish this from the true discount system by the great variation and lack of method with which such discounts are given. At best it is little better than guess-work, and it is probably just to say that bills made out upon this basis are almost never correct.

If guess-work is necessary, it would be preferable to charge customers an arbitrary rate per month or year, based entirely upon judgment and experience, and thus save the cost of meters.

The discount system is a step in advance, but, like the other, takes no account of the A and B items during a customer's absence or varying loads. It is only when the customer is consuming his average current that these items are properly allowed for, and if the monthly consumption should be greater or less than usual, the charge will be correspondingly too great or too small, although the variation from the true amount will be very much less than with the previous system. This point seems not to be generally understood. It is also claimed for the discount system that it has a strong tendency to promote consumption, and this is undoubtedly so. By means of the discounts it is endeavored to make the actual rate for current the same in each case, but the large consumers will be getting a greater return for their money, because the fixed charges in their case are a smaller part of the whole.

In order to insure against a customer's A and B expenses becoming a source of loss under any circumstances, another system has been made use of, in which each customer must pay at least a certain sum per mnoth, or, in other words, the system of minimum charge. This method has all the defects of the ordinary system, and the charge will seldom be correct except when it is equal to the minimum charge. If used in conjunction with the discount system, however, it will become much more nearly exact, and has been very successfully

applied in a number of cases. In this latter form, it suggests still another system in which the remaining difficulties have been largely removed, and which it was the principal object of this paper to bring to the attention of central station managers.

As has already been stated, the four chief considerations in determining the proper method of charging for current are simplicty, popularity, precision, and the effect on consumption as a whole. The last two of these will necessarily be the first to be considered, and then the system must, if necessary, be rounded off or altered sufficiently to satisfy the other conditions. Fortunately, however, if precision is attained, the tendency of the current consumption to increase will be consequent for a reason that will presently appear, and it will then only remain to make the system sufficiently simple and popular.

The cost of supplying any customer will depend upon the total number of consumers, his equipment, and his consumption. Obviously then, if the charge is to be correct, it must consist of the sum of his share of each of the three classes of items, plus a certain profit due the operating company. For each customer the A and B expenses remain constant, except as from time to time they are reduced when the business of the company warrants it. Their sum will therefore constitute a base rate which, added to the charge for current, gives a complete solution of the problem from the standpoint of precision. As the base rate through the A items is directly dependent upon the total number of consumers, it will be advantageous to every one to make this number as large as possible. Moreover, the greater the amount of current a consumer uses the less will be the ratio of the base rate to the total charge, and these facts, in conjunction with a precise system, will undoubtedly have a tendency to promote consumption.

It will at once be evident that this is radically different from the system of minimum charge, and its advantages should also be apparent. It is equally simple, more exact, shouid become more popular and reduce the price of electric lighting below that possible with the less precise systems. It shows at once at what figure it will be profitable to accept a doubtful customer, and every consumer becomes a source of revenue proportional to his current consumption, and there is no possibility of its being otherwise. It possesses in common with the system of minimum charge, the disadvantage of being objectionable to a certain class of consumers, but it should be remembered that these are the very ones who, either because they are away a large part of the time or are very small and uncertain consumers, are undesirable customers.

It seems to the writer that the question of popularity will be largely determined by the manner in which this system is applied. Bearing in mind that the chief objectionable feature will be the necessity on the part of each customer of paying his base rate under all circumstances, this charge should be made as small and payments upon it as easy as possible. To do this the company should figure all the A and B items strictly at cost, and profits be made on the sale of current only. When a customer is consuming no current, he can thus remain on the company's books and connected to its service, if he so desires, indefinitely, without being a source of loss, and, on his part, feeling that he is only paying the company what he is actually costing it.

Another way to make this matter appear in a more favorable light will consist in so wording the contract as not to make it appear offensive, and at the same time so that it will convey to the customer's mind the reason and entire fairness of the arrangement. For instance, the following might represent clauses in such a contract:

(3) The subscriber agrees to use current only for the purposes and in the manner and amount above specified, and pay therefor on or before the 10th day of each month, at the rate of —— cents per kilowatt hour, as may be shown by the reading of the meter installed in his premises.

(4) The subscriber further agrees, in consideration of the exceptionally low rates herein above provided, and in accordance with the requirements of the system of charge which renders such rates possible, that he will pay in addition to the charge for current as above specified $—— per year, averaging $—— per month, for the use of the company's apparatus under this contract, and as his share of the fixed operating expenses of the company, which are independent of current consumption. And,

(5) The subscriber further agrees that this fixed charge, or base rate, may at the option of the company be rendered and collected each month, provided that he shall receive the benefit of any reduction which may, during the time he continues to use current, be made to consumers of his class. And,

(6) The subscriber further agrees to give the company —— notice if he should desire to have his service discontinued, and that if at a subsequent time he should again wish to be connected, to pay therefor a sum not exceeding $——.

This last clause is necessary in order to prevent customers ordering the service discontinued during their absence, to avoid the payment of the base rate, when such absence is of brief duration.

In conclusion, it should be noticed that the system is general and applicable to any case. It is more necessary in the smaller stations, for the reason that the load in these is so uncertain and variable. Such special methods as those of Wright or Kapp can be readily introduced, and no change is necessary where there is also a power load upon the station. The various consumers are readily divided into classes depending upon their equipments and the nature of their current requirements, and each class will have its own perfectly definite and fixed base rate. These base rates will of course be the same as the minimum charge in that system. The advantage lies in the fact that this system is much more exact, and for that reason the charge to customers of and above the average size will be materially reduced, becoming, in fact, less than is possible with ony other of the present systems.

FERRARIS AND ARNO'S SYSTEM OF ALTERNATE CURRENT ELECTRIC DISTRIBUTION.[1]

PROFS. G. FERRARIS and R. Arno, of Turin, Italy, have developed a new system of electric distribution of energy with alternate currents, which enables them to supply power, in combination with light, from single-phase alternate current circuits. This device overcomes the troubles of running either lights with polyphase systems or motors with single-phase systems. The new system can also be readily adapted to run motors on existing single-phase circuits, such as are now exclusively used for light. In the new system the general distribution is done with a single-phase alternate current which supplies, in the ordinary way, all the light, but where it is necessary to run electric motors from the main current other alternate currents are drawn off, which have the required voltage and are conveniently shifted in phase so to reproduce in such places a system of multiphase distribution.

The new system of distribution is based on the use of phase-shifting transformers. This name is given to apparatus which, with a given primary current, reproduces a secondary current which, while it has the required voltage and intensity, still has the phase, in a convenient ratio, different from the phase that would exist in the secondary current of an ordinary transformer. These phase-shifting transformers have, like the ordinary transformers, fixed coils, primary and secondary, but they have also an intermediate rotating part whose rotation is maintained like that of an armature of a single-phase synchronous motor.

The working of this apparatus may be explained by considering the performance of an induction motor, for instance, a two-phase motor.

Let us have a two-phase motor made of two coils, AA^1 and BB^1, Fig 1, with the planes at 90 deg., and a short-circuited armature K. If we send into AA^1 and BB^1 two alternate currents with 90 deg. difference in phase, the armature K starts to turn in the same direction of the rotation of the rotary field, resulting from the two alternate magnetic fields produced by the two currents. Vice versa, Professors Ferraris and Arno have demonstrated that if while in one of the two coils is passing an alternate current, for instance in AA^1, we turn the armature K, then in the two coils AA^1 and BB^1 are produced two alternate e. m. f.'s, between which exists a difference of phase of a quarter period, and consequently if the ohmic resistances of the two coils is small, we have also a difference of phase of nearly 90 deg. between the two tensions at the terminals of AA^1 and BB^1. By properly proportioning the number of turns in the two coils we can obtain any ratio between the two e. m. f.'s.

In this way the apparatus represents a transformer in which the coil AA^1 is the primary and BB^1 the secondary. Such a transformer can have, as an ordinary transformer, that ratio of transformation which is desired, but differs from an ordinary transformer as the phases of the e. m. f., voltage and current in the secondary coil differ by a quarter period from the phases that we would obtain, keeping the other conditions the same, from the secondary coil of an ordinary transformer. The armature, once brought up to a convenient speed, will maintain its rotation by the effect of the same alternate current in AA^1 as in an ordinary asynchronous single-phase motor.

In ordinary practice, the phase-shifting transformer will be connected to the circuits as an ordinary transformer, namely, the primary coil AA^1 will be connected to the two

[1] "L'Elettricita."

high-tension primary conductors C and D, and the secondary coil BB[1] to a secondary circuit, R, at low tension. Combining (Fig. 2) this latter circuit, R, of the phase-shifting transformer Tf, with the circuit R of an ordinary transformer, T, we obtain a two-phase system at low tension. In this way the same primary line with single-phase, high tension alternate current can feed single-phase secondary mains at low tension for light, and, where required, two-phase secondary mains at low tension for electric motors.

Fig. 3 gives an illustration of the system adopted to feed

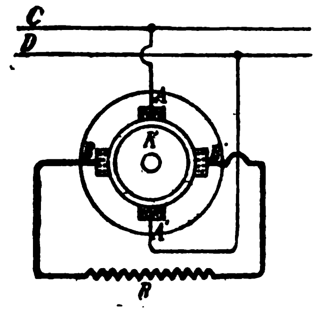


FIG. 1.

two-phase mains: C and D are two primary conductors of an ordinary high-tension alternate current line, TT ordinary alternate current transformers, P and Q the secondary mains distributing the low tension alternate current generated by TT, and Tf is a shifting phase transformer of which the primary coil, AA[1], is connected to the same high tension conductor, C and D, to which are also connected the primary coil aa[1], aa[1], etc., of the ordinary transformer TT.

Connecting two conductors, R and S, to the terminals B and

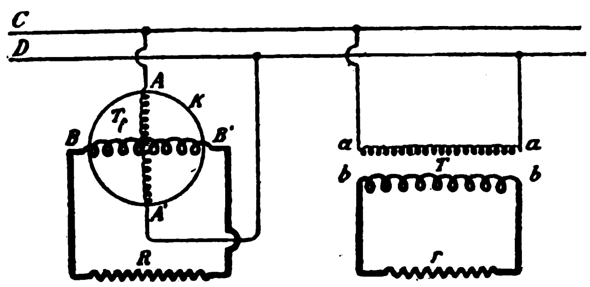

FIG. 2.

B[1] of the coil BB[1] of the shifting phase transformer, the latter will generate and the conductors will carry a current at low tension with the shifted phase to the different points where, besides the lamp L, it is needed to run the motors M. We create in this way different two-phase systems at low tension, with four wires, P and Q, secondaries of ordinary transformers, R and S, secondaries of the shifting phase transformers. Connecting together the point B[1] and b of Fig 2, we save

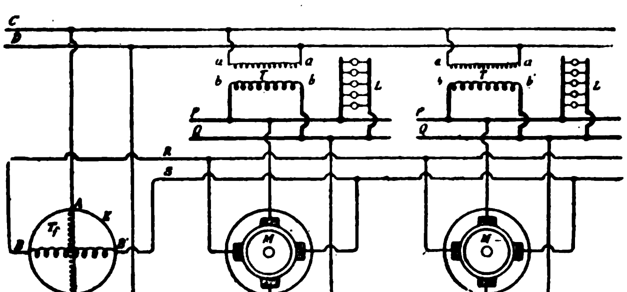

FIG. 3.

one conductor and obtain a three-wire system having two alternate e. m. f.'s, differing in phase by 90 deg.

In an analogous manner, instead of three-wire, two-phase systems, we can obtain three-wire, three-phase systems, using the transformer which shifts the phase by 120 deg., instead of 90 deg. And also higher phase systems can be obtained, increasing the number of wires and introducing different e. m. f.'s conveniently shifted in phase from each other.

Fig. 4 shows an application of the three-wire, two-phase system applied to electric traction. The third wire is represented by the rails, which carry the low tension current from the shifting phase transformer Tf, to start the motors which are also connected to the secondary mains of transformers TTT, supplied by the high-tension feeders C D. The motors, once started, do not require any more current from the third wire as they run, as stated above, like single-phase asynchronous motors. For this special feature, in ordinary practice

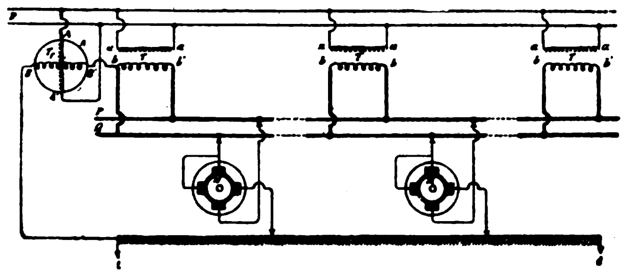

FIG. 4.

the shifting phase transformer and the conductor from it will have a limited capacity, say, large enough to start the biggest motor on the circuit or any number of small motors whose total capacity does not exceed the capacity of the largest motor, and as the large motors will, in practice, be kept running almost continuously, these will not interfere with the running of small motors which will be thrown on and off at the same time, also in large number. When starting large motors a lamp on the circuit, or any other signal or mechanical device, can prevent other motors from being started at the same time, which amounts only to a few seconds.

ON A NEW FORM OF RADIATION.[1]

BY PROF. WILHELM KONRAD RÖNTGEN.

As my investigations will have to be interrupted for several weeks, I propose in the following paper to communicate a few new results.

§ 18. At the time of my first communication it was known to me that X-rays were able to discharge electrified bodies, and I suspected that it was X-rays, not the unaltered cathode rays, which got through his aluminum window, that Lenard had to do with in connection with distant electrified bodies. When I published my researches, however, I decided to wait until I could communicate unexceptional results. Such are only obtainable when one makes the observation in a space which is not only completely protected against the electrostatic influences of the vacuum tube, leading-in wires, induction coil, etc., but which is also protected against the air coming from the vicinity of the discharge apparatus. To this end I made a box of soldered sheet zinc, large enough to receive me and the necessary apparatus, and which, even to an opening which could be closed by a zinc door, was quite airtight. The wall opposite the door was almost covered with lead. Near one of the discharge apparatus placed outside, the lead-covered zinc wall was provided with a slot 4 centimetres wide, and the opening was then hermetically closed with a thin aluminum sheet. Through this window the X-rays could come into the observation-box. I have observed the following phenomena:

(a) Positively or negatively electrified bodies in air are discharged when placed in the path of X-rays, and the more quickly the more powerful the rays. The intensity of the rays was estimated by their effect on a fluorescent screen or on a photographic plate. It is all the same whether the electrified bodies are conductors or insulators. Up to the present I have discovered no specific difference in the behavior of different bodies with regard to the rate of discharge, and the same remark applies to the behavior of positive and negative electricity. Nevertheless, it is not impossible that small differences exist.

(b) If an electrical conductor is surrounded by a solid insulator, such as paraffin, instead of by air, the radiation acts as if the insulating envelope were swept by a flame connected to earth.

(c) If this insulating envelope is closely surrounded by a

[1]Second communication. For the first communication to the Würzburg Physico-Medical Society see The Electrical Engineer, Feb. 12.

conductor connected to earth, which should, like the insulator, be transparent to X-rays, the radiation, with the means at my disposal, apparently no longer acts on the inner electrified conductor.

(d) The observations described in a, b and c tend to show that air traversed by X-rays possesses the property of discharging electrified bodies with which it comes in contact.

(e) If this be really the case, and if, further, the air retains this property for some time after the X-rays have been extinguished, it must be possible to discharge electrified bodies by such air, although the bodies themselves are not in the path of the rays.

It is possible to convince oneself in various ways that this actually happens. I will describe one arrangement, perhaps not the simplest possible. I employed a brass tube, 3 centimetres in diameter and 45 centimetres long. A few centimetres from one end a portion of the tube was cut away and replaced by a thin sheet of aluminum. At the other end an insulated brass ball fastened to a metal rod was led into the tube through an air-tight gland. Between the ball and the closed end of the tube a side tube was soldered on, which could be placed in communication with an aspirator. When the aspirator was worked the brass ball was surrounded by air, which on its way through the tube went past the aluminum window. The distance from the window to the ball was over 20 centimetres. I arranged the tube in the zinc box in such a manner that the X-rays passed through the aluminum window at right angles to the axis of the tube, so that the insulated ball was beyond the reach of the rays in the shadow. The tube and the zinc box were connected together; the ball was connected to a Hankel electroscope. It was seen that a charge (positive or negative) communicated to the ball was not affected by the X-rays so long as the air in the tube was at rest, but that the charge immediately diminished considerably when the aspirator caused the air traversed by the rays to stream past the ball. If the ball by being connected to accumulators was kept at a constant potential, and if air which had been traversed by the rays was sucked through the tube, an electric current was started as if the ball had been connected with the wall of the tube by a bad conductor.

(f) It may be asked in what way the air loses this property communicated to it by the X-rays. Whether it loses it as time goes on, without coming into contact with other bodies, is still doubtful. It is quite certain, on the other hand, that a short disturbance of the air by a body of large surface, which need not be electrified, can render the air inoperative. If one pushes, for example, a sufficiently thick plug of cotton wool so far into the tube that the air which has been traversed by the rays must stream through the cotton wool before it reaches the ball, the charge of the ball remains unchanged when suction is commenced. If the plug is placed right in front of the aluminum window the result is the same as if there were no cotton wool, a proof that dust particles are not the cause of the observed discharge. Wire gauze acts in the same way as cotton wool, but the meshes must be very small and several layers must be placed one over the other if we want the air to be active. If the nets are not connected to earth, as heretofore, but connected to a constant potential source of electricity, I have always observed what I expected; however, these investigations are not concluded.

(g) If the electrified bodies are placed in dry hydrogen instead of air they are equally well discharged. The discharge in hydrogen seems to me somewhat the slower. This observation is not, however, very reliable, on account of the difficulty of securing equally powerful X-rays in successive experiments. The method of filling the apparatus with hydrogen precluded the possibility of the thin layer of air which clings to the surface of the bodies at the commencement playing an appreciable part in connection with the discharge.

(h) In highly-exhausted vessels the discharge of a body in the path of the X-rays takes place far slower—in one case it was, for instance, 70 times slower—than in the same vessels when filled with air or hydrogen at atmospheric pressure.

(i) Experiments on the behavior of a mixture of chlorine and hydrogen, when under the influence of the X-rays, have been commenced.

(j) Finally, I should like to mention that the results of the investigations on the discharging property of the X-rays, in which the influence of the surrounding gases was not taken into account, should be for the most part accepted with reserve.

§ 19. In many cases it is of advantage to put in circuit between the X-ray producer and the Rhumkorff coil a Tesla condenser and transformer. This arrangement has the following advantages: First, the discharge apparatus gets less hot, and there is less probability of it being pierced; secondly, the vacuum lasts longer, at least this was the case with my apparatus, and thirdly, the apparatus produces stronger X-rays. In apparatus which was either not sufficiently or too highly exhausted to allow the Ruhmkorff coil alone to work well, the use of a Tesla transformer was of great advantage.

The question now arises—and I may be permitted to mention it here, though I am at present not in a position to give an answer to it—whether it be possible to generate X-rays by means of a continuous discharge at a constant discharge potential, or whether oscillations of the potential are invariably necessary for their production.

§ 20. In Sec. 13 of my first communication it was stated that X-rays not only originate in glass, but also in aluminum. Continuing my researches in this direction I have found no solid bodies incapable of generating X-rays under the influence of cathode rays. I know of no reason why liquids and gases should not behave in the same way.

Quantitative differences in the behavior of different bodies have, however, revealed themselves. If, for example, we let the cathode rays fall on a plate, one-half consisting of a 0.3 millimetre sheet of platinum and the other half of 1 millimetre sheet of aluminum, a pin-hole photograph of this double plate will show that the sheet of platinum emits a far greater number of X-rays than does the aluminum sheet, this remark applying in either case to the side upon which the cathode rays impinge. From the reverse side of the platinum, however, practically no X-rays are emitted, but from the reverse side of the aluminum a relatively larger number are radiated. It is easy to construct an explanation of this observation, still it is to be recommended that before so doing we should learn a little more about the characteristics of X-rays.

It must be mentioned, however, that this fact has a practical bearing. Judging by my experiments up to now, platinum is the best for generating the most powerful X-rays. I used a few weeks ago, with excellent results, a discharge apparatus in which a concave mirror of aluminum acted as cathode and a sheet of platinum as anode, the platinum being at an angle of 45 deg. to the axis of the mirror and at the center of curvature.

§ 21. The X-rays in this apparatus start from the anode. I conclude from experiments with variously-shaped apparatus that as regards the intensity of the X-rays it is a matter of indifference whether or no the spot at which these rays are generated be the anode. With a special view to researches with alternate currents from a Tesla transformer, a discharge apparatus is being made in which both electrodes are concave aluminum mirrors, their axes being at right angles; at the common center of curvature there is a "cathode ray catching" sheet of platinum. As to the utility of this apparatus I will report further at a later date.

DISTRIBUTION BY ALTERNATING CURRENTS.

We print below an abstract of the interesting discussion of Mr. W. L. R. Emmet's convention paper, on "Results Accomplished in Distribution of Light and Power by Alternating Currents."

Mr. Wagner inquired whether the three-wire, two-phase machine, when operating three wires in place of four, would have 42 per cent. less capacity for lighting. Mr. Emmet replied that such would be the case when operating single-phase instead of two-phase, and drew a diagram on the blackboard, illustrating the point.

Mr. Ayer referred to transformer sub-stations or secondary feeders located at intervals. It was being done abroad considerably, and also in Chicago Mr. Van Trump said he was operating a two-phase system, synchronous motor, driving Edison generators on three-wire system, and the system worked beautifully, with only one exception, which he was unable to explain. That is, with perfectly steady and even load on the Edison generators and no fluctuations whatever in the speed of the generators, there appeared to be a slight fluctuation on the alternating current mains, as though the motors tended to get out of synchronism. They did not pull out of step, however, even on overload. He thought it was due to a difference in the curve of the generator and the motor. It would be so fast that one could hardly notice it at times.

Mr. Emmet thought it was probably due to variation in the speed of the prime mover. A tendency of the prime mover to vary speed would cause a tendency to pull apart; every time the generator varied the least bit in speed, it would tend to pull out, and in doing so would cause a variation in the voltage, and that might take almost any form of vibration. The only remedy was an absolutely uniform speed of generator.

Mr. C. F. Scott, in answer to a question by Mr. De Camp,

stated that large transformers for supplying a number of customers will in general be more economical in the amount of power required for operation and also in the first cost, over the usual plan of supplying each customer by an individual transformer. The capacity of the large transformer may be less than the aggregate capacity of the small transformers which will be required. The cost of secondary mains may be prohibitive, however, if the district is a very large one, or if the service is underground, and the cost of individual connections is high. If the mains must go underground, it would be just as necessary to run the primaries underground with the house connections of the primary mains, which would be more expensive than the secondary mains. This question is one which depends largely on the conditions. In general, he believed in the use of the secondary mains, and believed this would be found the most economical, except in very exceptional cases.

Mr. Scott said that there were one or two points in the paper which he would bring up for general discussion. In a comparison of the three-phase and two-phase systems of distribution, one of the points which confronts the customer is the measurement of the power on the two systems, both commercially for the sale of power and light, and for determining what is going on in the system; the measurement of current in different branches or the measurement of power in different branches. The three-phase sytem is so interconnected that, without elaborate or extended measurements or calculations, it may be impracticable to determine the load on the three circuits, what the relative load is; whereas, on the two-phase system, where the circuits are independent in action, except to a very slight extent, the measurement of what goes on in one circuit—the measurement of the current in one circuit—would indicate the amount of current supplied to the devices connected with that circuit. In general, the amount of power measured directly in one circuit, added to the amount of power measured directly in the other circuit, will give the total power. If the conditions are a little abnormal, or something is wrong, the very time when the ordinary operator wants especially to know where the trouble lies, the two-phase system, with independent circuits, seems to be the best arrangement; and in some cases in practice has given much less trouble to the ordinary electrician than the three-phase system does.

A method of secondary distribution which has not been widely used, but is being introduced, and it seems has a useful future before it, is the three-wire system, with a modification in which only two wires are run from the central station, or in which only two secondary mains may be required, instead of three, which reduces the number of house connections required. In this case a 200-volt circuit might be used as secondary mains, and two connections made to a customer. On the customer's premises, a balancing coil, a coil in the form of a converter, with a single winding, adapted for 200 volts, the two ends of the coil being connected to the 200-volt circuit, and a loop brought out from the middle of the coil, from which point 100 volts may be measured to either of the secondary mains, could be used for the connection of the middle or neutral wire. This coil would serve to preserve a balance between the two circuits, so that, should the number of lamps be greater on one circuit than on the other, the electromotive force would be practically balanced. This simplifies the three-wire system. The loss in balancing coils may be very slight. The balancing coil is a form of converter which will give a very large output, and its capacity need be only that required for the difference in the number of lamps on the two circuits; say there are 25 lamps on one circuit and 75 lamps on the other circuit, the capacity of the coil would be 50 amperes, whereas the total number of lamps on the circuit would be 100. The size of the coil required for this difference in lamps would be the same as would be required for only 25 lamps, if made in the ordinary form of a two-coil converter, so that the cost of these secondary balancing coils need only be quite small.

The system of two-phase distribution shown in Fig. 4 of Mr. Emmet's paper, in which the generator is wound with closed circuit and the terminals brought out at either of four points, two being used for single-phase lighting, and one of the other leads being used in connection with motor work, requires the use of but three wires to any point where motors are required. The use of four wires here is usual in many cases for motors, if the power required by the motors be large. The effective potential of distribution for motors is about 700 volts upon each of the two side circuits, if the lighting be done at 1,000 volts, and the motor be run from three wires; but if all four wires are used, then the effective potential for motor service is 1,000 volts in the transmission line on each of the two circuits. Thus, if the quantity of power to be delivered by the motors is considerable, the use of four wires may lead to a saving in the cost of conductors, making it well worth while to run them. This kind of generator admits of this connection very readily. The only disadvantage of this system that has been pointed out, but is said to be the greatest one, is the reduced capacity of the generator. That point has already been discussed. It is usually satisfactory to the customer to know that he can buy a dynamo for a certain price to do single-phase work, regardless of what the dynamo may do if operated in some other way.

The supplying of motors from a dynamo of this kind by three wires involves the two-phase three-wire system, in connection with which the unbalancing of the two circuits has been pointed out. This unbalancing will tend to unbalance the motor circuits, raising one and lowering the other. This system is best adapted for a large percentage of lighting load, with a motor load as an auxiliary, as is the case in general station practice. In that kind of service the unbalancing of the two circuits does not affect the lighting part, where closeness of electromotive force is required, but affects only the motor work, where the electromotive force is not required to be adjusted with the same nicety. With a motor load, the unbalancing is not quite as great as it is on lighting loads, due to this mutual induction betwen the two circuits. The effect of the unbalancing in the example in the paper is extreme, and results largely from the high frequency of 125 cycles. At low frequencies, the effect would be very greatly lessened.

Mr. Scott desired to reinforce what was said in the latter part of the paper about the flexibility of the alternating system, coming into actual practice. They had heard about the flexibility of this system for a long time; its adaptability to all kinds of service. The example given in the latter part of the paper shows how that is being done now on a large scale, and the Hartford, Conn., plant was one that had come to his attention lately, and he had gone into the details of it. One machine may act as a generator, driven by an engine, supplying power to the city, or it may be run as a generator in multiple with machines at two different stations, ten miles away, or which may be run as a synchronous motor for replacing the engine; this showed a flexibility which ought to find application elsewhere. The running of this current through rotary transformers, for supplying storage batteries, was also an application which ought to be adopted elsewhere. He had heard this plan criticised on one ground, and that was that it did everything, except that the storage batteries did not run back through the rotary transformers and alternating current motor and make steam in the boilers!

Mr. Emmet, referring to the point that Mr. Scott made about the use of compensators, that is, an adjusting device for supplying current to a three-wire system, said that with alternating current we can use such compensators, just as Mr. Scott said; but in practice they would have to be somewhat larger. It might be in certain cases that large compensators are desirable in connection with a three-wire alternating system to help out at some remote point, making it possible to reduce the number of transformers in use in getting over large areas without trouble from unbalancing; but the general distribution of compensators in small units of 10 or 20 lights, such as customers in stores, would seem to be hardly a practicable scheme.

Mr. Dow: I began to use large transformers for 150 to 250 lights in 1889, with entire satisfaction, and found that the very best results could be had; the economy being in first cost, due to the fact that a block where 500 lights were scattered in stores and offices could be served by 250 light transformers, with a reduction of the iron losses. I have had no reason since 1889 to change my mind, and the practice is now to put in the largest transformers we can find; and when the conditions are equal as to cost, and a little against the secondary main, I have found the transformer preferable.

As to the two-phase, three-wire system, I can say from practice that where a large building is wired with the Edison three-wire system, and the neutral is usually of the same size as the two outer wires, in almost every case that system can be used without interference or objection at all from induction or any other trouble. In three cases to my knowledge, in buildings with 600 or 800 lights, we have the Edison three-wire system, and the users did not know the difference. The essential point is that they are not so apt to create a drop in the building. The case is given where the building is wired with the neutral; it is the same size as the outer wires. That method is entirely acceptable, and can be used every time.

I wish to ask: Is there nothing better for series arc light circuits, in connection with the alternating station, than the running of the well-known series dynamos by a motor? Is there no prospect of series alternating arcs, such as might be used for street lighting, assisted by a rectifier system such as is used in England, outside of what is now available up to 50 and 60 light circuits?

Mr. Wagner: Mr. Dow, I think, refers here to a synchronous motor, used to drive counter-shafting, which in turn ope-

rates arc light generators. That could be done in any alternating current station, and the arc machines are operated in that way from the alternating current generators. But it would hardly be an economic way to operate unless it was possible to operate the arc light machines at a distance from the station where steam power could be directly applied. Arc lights can now be operated satisfactorily directly from the alternating current circuits, either using a transformer for each arc lamp or a transformer for a number of arc lamps. I am experimenting in this line, of operating a large number of arc lamps for street lighting from alternating current generators. The system used is one which admits of the use of the ordinary circuits, such as are used for series arc lighting, and with the lamps placed in somewhat the same way. As many lamps as desirable can be operated, I was going to say, but that is limited by the potential. I am now operating as many as 75 lamps on one transformer, and that does not seem to be the limit of the number that can be operated. The system has not been in operation long enough to determine positively its success, and, therefore, I am not quite prepared to furnish all the details. I hope to be able to do so before long; and if it is a success, it will be a very economical way of operating arc lamps in connection with incandescent lighting, by means of alternating current. Arc lighting, incandescent lighting and power can then be furnished from the same generator.

Mr. Ayer inquired whether Mr. Wagner meant to say his system would prove to be economical in a case where 30 per cent. of the station load, as in the case in St. Louis, are arc lights for a large number of hours—several thousand arc lights; whether it would be wise to supply them from the alternating generators, and whether one can introduce stationary transformers in place of direct current transformers, as in the case of driving directly motor generators supplying direct current, or driving existing arc dynamos with motors possibly operated from alternating circuits, or driving directly from the engine.

Mr. Wagner: The point is well taken about the relative proportion of arc and incandescent lighting to be furnished by alternating generators; and as to the economy of so doing I will simply say in answer that it is my firm conviction, which has not yet been proved, that it will be economical to operate not only 30 per cent. of the entire load with arc lamps, but it will be economical where the entire load is arc lamps; but, as I say, that is my opinion. I cannot say it is an established fact.

Mr. Ayer thought the sytem involved serious loss in distribution.

Mr. De Camp asked Mr. Wagner if he had now thrown upon him the responsibility of installing a 1,000-light plant, with arc lamps alone, without any other lighting, whether he would do that installing from, say, four 250-light direct machines, such as we had to-day, or whether he would put in two alternating machines to do it.

Mr. Wagner: I can say that I have taken the responsibility for a larger number of arc lamps than Mr. De Camp mentions, and I cannot say yet whether my head is coming off or not. (Laughter.) It strikes me that Mr. Dow's question might be tersely put by saying, "Is there to be a feasible series of alternating arc lamps?"

Mr. Dow: I have been over this question for four years; I have got to go through it again this fall, the same identical question, with an investment back of it. I have had heretofore to advise the parties interested to put their money into old line machines. I have succeeded in getting higher voltage, greater economy in distribution and great efficiency from the larger machines, but up to the present time I have not found an ideal system. I can answer the question as to the lamps. This present year series alternating arc lamps do work and can be made to work, and alternating lamps can be had which apparently will make just as little trouble as the old line direct lamps. Last year I should have had to say that there was no alternating lamp that could be relied upon and stay in service as long and without complaint as the old style of lamp.

I can throw a little light on the problem concerning rectifiers from recent correspondence with English engineers. The rectifier has been in use in England for four years all told. It began with a 20-light size and has got up to a 60-light size, and there seems to be nothing to prevent its development beyond that limit except the conservatism of the English engineers, who think that 3,000 volts is pretty near the jumping-off place. The efficiency of the device in connection with a first-class alternator, and in its development, is identically the same efficiency that I am getting in my own practice with a 50-kilowatt, 110-volt arc-lighting machine. The efficiency is 73 per cent. from the indicated horse-power through the mains to the output in kilowatts. The output is not in a pulsating current, such as might be had with a rotating coil armature, with a two-part commutator. The light is, to all intents and purposes, a direct current arc, and not the alternating current arc. A series transformer and regulating device gives the same characteristics in the light as arc light dynamos in use in the United States. They have considerable self-regulation. The limiting voltage, as I say, in practice, is 3,000 volts. The limitations appear to be in the commutator. On this side we have succeeded in making commutators operating with 6,000 volts. I do not see why a motor synchronously driven should not operate just as well on the commutator as on a dynamo shaft. I cannot see that there is any difference between the open coil commutator of the well-known types and the rectifier commutator driven by a synchronous motor. The two devices appear to be the same. I look for something in that line and hope to see that same rectifier taken up by some American engineer and experimented with as to its usefulness in alternating transmission over long distances.

The efficiencies I am now getting I believe are as good as the average for public lighting: 8½ per cent. losses in the lines. The lines when fully loaded are more economical, and give 7½ per cent. I believe that is better than the average, and may be considered as a first-class representation of a modern station of that class. I doubt if an alternating system will succeed in increasing that efficiency; and I am afraid that high voltages, 5,000 or 6,000 volts, will be essential in public lighting, as long as the city fathers consider it necessary to have lights in sparsely settled outlying wards.

I have considered as an interesting problem the question of getting down to 3,000 volts; changing from 5,500 to 3,000 volts. I found I should have to double my investment in copper, and that the line losses would, on account of series distribution, be exactly doubled over what they are now, which would be 17 per cent., instead of 8½ per cent. That would be the condition involved in changing from 5,000 to 3,000.

Mr. Ayer: You state that the losses in the distributing system which you experimented with amounted to about 27 per cent. between the indicated horse-power and the output of the machine, with the Ferranti system. What are your losses between your indicated horse-power and your lamps in your regular commercial operation? Mr. Dow answered that, adding to the 73 per cent. at the dynamo terminals, the line losses of 7 per cent., say 66 per cent. would be shown at the lamps. The rectifiers operate at 50 periods per second.

Mr. Emmet drew attention to the fact that constant current apparatus running from alternating circuits must involve the use of a large amount of idle current in the circuit. This, on a large scale, was objectionable, particularly if anything else was operated in the same system. It seemed to be one of the worst limitations of the rectifier system. The frequency at which the rectifier has to operate to go on alternating circuits made it very different from the commutator on an open coil arc machine—for example, a Brush machine. Mr. Dow remarked that the Ferranti machine operated also at 83 p. p. s. Mr. Emmet expressed his doubts as to the commercial practicability of rectifiers on long circuits.

Mr. Wagner remarked that central station managers who were anxious about their heads would do well to stick to well tried systems. Most of his directors had heard from a great many electricians over the country that the system he was trying would not work, and they ought to know. (Laughter.)

Mr. Black: One important point has been left out of the discussion, that is, the efficiency of the alternating current lamp as compared with the direct current lamp. What we want is the maximum amount of light with the minimum amount of power, and in all photometric tests I have seen accounts of, the light derived from the alternating arc has not been more than about 50 to 75 per cent. of that derived from the direct current arc on the same watts dissipated. In that case it seems to me that it is absolutely impossible ever to run commercial arc lights from an alternating system without a rectifier of some description.

ELECTRICAL PHILOSOPHY.

"That was a curious case of Kadger's. He married the eldest daughter of the Bingler family, outlived her, married the next eldest, outlived her also, and then married the youngest."

"Why didn't he begin with the youngest and marry the eldest one last?"

"Well, I suppose he naturally followed the line of least resistance."—Chicago Tribune.

MR. H. C. TOWNSEND, the well-known patent attorney and expert, left for Europe by the New York last week on important business affairs.

THE LIGHT OF THE FUTURE.[1]

BY D. McFARLAN MOORE.

THE lecture was opened by Mr. Moore with a review of the work that has been done heretofore in lighting vacuum tubes having electrodes and incandescent lamp bulbs with various arrangements of filaments, and referred to by him in his paper read at the meeting of the American Institute of Electrical Engineers April 21 and published in The Electrical Engineer of April 29.

After explaining the relations between the kind and quantity of light produced in tubes of different degrees of vacua, and giving a brief description of the vacuum vibrator described in the paper mentioned above, experiments with electrode tubes were described at some length.

If we substitute for a tube with terminals another which is its exact counterpart in form and size, except that it is entirely devoid of electrodes, we will observe after the wire terminals are each wrapped several times around its outside at its ends, that the light is perfectly steady. This feature is of great importance, but it is second to the fact that there is nothing within the tube save the residual gas, and, therefore, its life is almost unlimited. On close examination, both sight and sound tell us that the wires at the end of the tube do not make good contact with the glass, and the slight sparking taking place is detrimental to the volume and steadiness of light. This is cured by painting the outside of the tube at its ends with a thick paint, made by mixing an alcoholic solution with powdered aluminum, and bringing the wire in contact with the paint. A tube has been treated in this manner, and the great increase in the volume of light is apparent. There is no necessity that the two coatings of metallic paint be of the same size; in fact, the one attached to the low potential terminal may be but one-half the size of the high potential coating. If a number of large insulated sheets of metal be connected to an electrode, the light is decreased thereby. Of course the result is the same if it be grounded.

These coatings can be placed at different parts of the tube and connected in a variety of ways to a number of vibrators; but maximum intensity of light occurs when coatings of equal size are placed at the ends of a tube and each connected to a high potential terminal of a vibrator, and the center of the tube attached to the low potential pole. That the light is largely due to the difference of potential, and that polarity is of little importance, can be shown in cases of this kind. The terminals of the tube can both be either high potential positive or both be high potential negative, or one end high potential positive and the other end high potential negative, and the middle terminal can be either low potential positive or negative,, but the tube is equally illuminated throughout its entire length in all cases.

To get the best light from a lamp, the terminal of greatest area must always be negative, irrespective of its potential; with tubes the case is different—that is, to get best light, the largest electrode should be the one of high potential, irrespective of polarity. This fact can be illustrated in the case of tubes with or without electrodes. An electrodeless tube is shown as it appeared under the discharge of a weak current. The apices of the cones of light from each end meet at a fixed point, which remains stationary whether the high potential terminal be positive or negative. With a tube of the same size, but provided with electrodes, the phenomena are the same, except that when the high potential is negative dark spaces appear for a distance of about one-fourth of an inch in front of both of the aluminum discs forming the electrodes; but when the high potential terminal is positive, the dark space appears only in front of the low potential and negative pole.

If three coatings made of tinfoil be insulated with oiled paper and placed one on top of the other at one end of a tube, and each coating connected to a high potential terminal of a vibrator, the light will be but slightly increased over that obtained from the same tube by a vibrator, but not so much as that obtained by three tubes each connected to a vibrator.

The importance of having close fitting metallic caps (best constructed by using a paint of metal powder) covering the glass at the ends of the tubes has already been touched upon. But if the electrical connection between the conductor and the glass is of such importance—and since it is the electrical action of the current on the inside of the glass that agitates the molecules so that they give forth light—the logical interrogation is, What part do the thickness and the composition of the glass play in the production of light?

First, as to thickness. Five tubes were made up, each 1 7-16 inches in diameter and 1 foot 3½ inches long. Tube No. 1 was made throughout of heavy glass, averaging ⅛ inch in thickness. Tube No. 2 was made of thin glass throughout, less than one-thirty-second of an inch in thickness. Tube No. 3 was made of glass of the same thickness as No. 1, except that the glass beneath the caps was as thin as possible; probably less than one-sixty-fourth of an inch. Tube No. 4, the same as No. 1, but provided with two aluminum discs acting as interior electrodes, besides having the exterior caps. Tube No. 5 the same as No. 1, but at its center was blown a bulb over three inches in diameter, causing its walls to be very thin.

Upon trial, no difference was discernible in the volume of light emitted by No. 1 and No. 2, and it was greater than that of No. 3. When the interior electrodes of No. 4 were used alone, the light was very poor, but subject to irregular, brilliant rushes of light with striations. When the exterior caps alone were used, the light was also poor, but steady. Where adjacent caps and discs are connected together striæ seem to find difficulty in formation, but the light is no better. All of these tubes were given the same degree of exhaustion, and were all made of American glass. Two other tubes received the same vacuum and were each 3 feet long and 1¼ inches in diameter; one of American (lead) glass, and the other of German (lime) glass, were tried on the same current vibrator and magnet. The tube of American glass, though it had walls appreciably thicker than the other, gave considerably more light.

The light from a tube 18 inches long by 1¾ inches in diameter of ordinary American glass, but with its ends 3 inches long, made of glass containing a maximum quantity of lead, was considerably less than that from a tube of the same size made entirely of ordinary American glass.

All these experiments go to show that the light is due to electrostatic phenomena. A given rate of vibration may produce maximum light in a lamp made by using a 16 candle-power incandescent bulb, but if an electrodeless tube be substituted for the lamp, it will give its maximum light only after the rate of vibration has been considerably increased. Too high a rate, however (obtained by varying the distance of the vibrator from the magnet core), will diminish the light.

If one end only of a tube be connected to the high potential terminal of the vibrator, the light will be greatest in the end of the tube nearest the cap connected, and if the other end be grounded or grasped in the hand, the light will increase many times. If one end only of a tube be connected to a low potential terminal of a vibrator, it is seldom that any light whatever results.

When two high potential bands are placed at the same end of the tube, but separated from each other, and one or two bands at the other end, an intense light will appear in the small space between the two high potential bands, and the main body of the tube will be almost dark.

An ordinary electrodeless tube connected in the regular manner will light up the instant the circuit is closed, provided the temperature of the room is normal; but if it be cold, five or ten seconds will elapse before light appears. If the tube has been used before, the moment any light at all appears it will be at its maximum; but if it be a new tube that has just been taken from the mercury pump, the light will at first appear cloudy, and will require a minute or two to clear up into an intense white.

Not only the temperature of the interior of the tube and the glass are affected by the current, but also that of the exterior electrode; and when sufficiently high and therefore more conducting, the discharge, evident in the form of light, results. Another way of illustrating how a disruptive discharge is aided by raising the temperature of the glass is shown by attaching a high potential lead to the shell of an incandescent lamp and a low potential lead to a small disc of tinfoil concentric with the top of the lamp. When the circuit is first closed for a moment there is no demonstration whatever; then a single streak of miniature lightning passes from the base of the lamp, a second later quite a number of discharges occur almost together and in a few moments the lamp appears to be encased in a cage of fiery streaks, due to the increased conductivity of the glass on account of its rise in temperature. Although these discharges occur spasmodically, nevertheless each separate discharge appears in the form of a comparatively short but continuous thread of light. I have, however, noted the discharge from a magnet the whole length of which was broken up into short dashes.

If a tube be bent in the form of a circle, care being taken that its ends do not touch, the light is but slightly affected. Also, if an endless tube be constructed with its terminals located at the ends of a diameter, the light is still the same.

An electrodeless tube was constructed 18 inches over all, 1 inch in diameter at the ends, 6 inches at its middle, and was

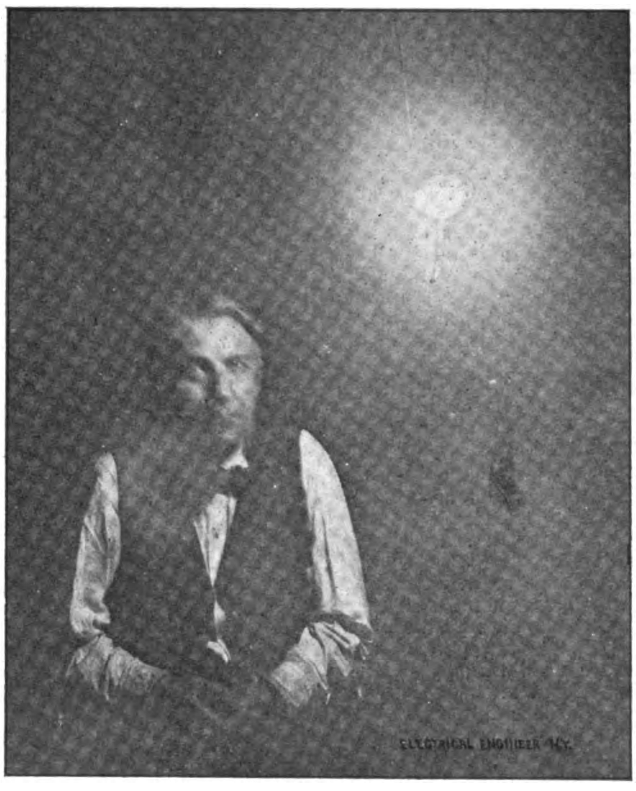
[1] Abstract of a lecture delivered before the National Electric Light Association, May 6, 1896.

one-half inch in diameter, but for 2 inches at the center it was one-quarter inch in diameter. The light was most intense in the center where the diameter of the tube was smallest; less intense in the parts one-half inch in diameter, and least intense at the ends; but the total amount of light given was the same as though the tube had been 1 inch in diameter its entire length, without any contracted portions. Again, the maximum production of light from a tube is directly dependent upon a certain proportion existing between the length and diameter of the tube. To prove this, here is a tube of the same diameter as those that give an excellent light, viz., 1 7-16 inches, but only 5½ inches over all in length and provided with caps 1½ inches long. The light produced is very poor, indeed. There is a tube of fixed dimensions that will give a maximum light for every stated amount of energy.

The problem heretofore has been to get a practical intensity of light from a vacuum tube, regardless of the method pursued or its economy; but since this result, through the agency of the vacuum vibrator, can now be obtained, the main problem has now resolved itself into one of economy. I am happy to say, however, that even here the vacuum vibrator shows an enormous advance over all other methods heretofore used; in fact, from comparative tests between the lighting by incandescence and by tubes of the hall of the A. I. E. E., it was shown that the efficiencies of the two systems do not differ greatly from each other. This is a remarkable statement, in view of the fact that heretofore their efficiencies were almost incomparable; and, secondly, that tube lighting is most decidedly in its embryonic state.

THE EDISON FLUORESCENT LAMP.

DURING the past week Mr. Edison has continued his experiments on his new fluorescent lamp, which, as announced by him in our issue of April 15, is made by fusing tungstate of calcium to the interior of an X-ray tube. When the tube is set at work the entire energy of the X-rays is ab-



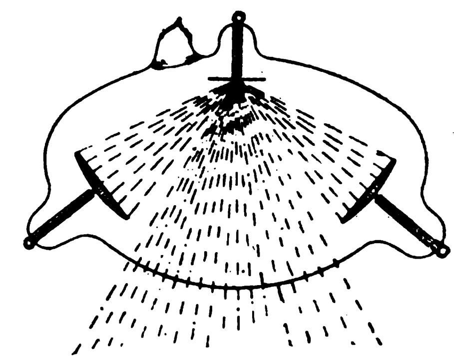
THE EDISON FLUORESCENT LAMP AS IT APPEARS IN MR. EDISON'S LABORATORY.

sorbed by the fluorescent material which emits light. Mr. Edison has found that such a tube shows an entire absence of X-rays externally, and, what is more, no rise in temperature can be detected with a clinical thermometer. Another curious fact noted is that when employed as fluorescent bodies within the tube, instead of outside, as usually employed, some substances develop a higher degree of fluorescence even than tungstate of calcium, which has thus far proved the best. As regards the efficiency of the new lamp, Mr. Edison has made preliminary measurements which seem to indicate a very high economy. Thus, measurements were taken on a lamp which Mr. Edison estimated to be of about 1 candle-power. The measurement was made by placing a Kennelly direct-current ammeter and a Weston direct-current voltmeter in the circuit feeding the primary of the induction coil connected to the lamp. The ammeter showed an average of 2 amperes, and the voltmeter 0.3 volt, which would indicate a consumption of 0.6 watt for the lamp of estimated 1 candle-power. This result is so remarkable that Mr. Edison himself has doubts as to the accuracy of the indications of the instruments, in view of the peculiar nature of the interrupted current obtained in connection with the induction coil. The current in Mr. Edison's experiments is interrupted over 14,000 times per minute. Mr. Edison proposes during the present week to carry out a complete series of accurate photometric and electrical tests with instruments and in a manner which will not be open to question as to their reliability. The accompanying engraving shows the new fluorescent lamp as it appears in Mr. Edison's laboratory. The photograph was taken by the light of the lamp itself with an exposure of about 30 seconds.

FOCUSING TUBE FOR USE WITH ALTERNATE CURRENTS.[1]

BY A. A. CAMPBELL SWINTON.

IN Professor Röntgen's second communication to the Würzburg Physico-Medical Society,[2] he states that he is constructing a special form of vacuum tube for use with alternate currents from a Tesla transformer. For those whose laboratories are supplied with alternating current, but who cannot readily obtain continuous current, a tube suitable for use with Tesla current is an advantage. The annexed illustration shows such a tube which I had made nearly two months ago. The



SWINTON'S ALTERNATE CURRENT X-RAY TUBE.

two curved aluminum discs serve alternately as cathode and anode according to the direction of the current, each focusing its cathode rays upon an identical portion of the flat platinum reflector. If carefully made, so that the foci of the two discs are exactly in the same point, the tube will be found to work well.

By connecting both discs together and using them as cathode, and employing the platinum as anode, the same tube will answer for Ruhmkorff currents.

PHOTOGRAPHS TAKEN IN THE INTERIOR OF CROOKES TUBES.

MR. G. DE METZ has presented a brief paper before the French Academy of Sciences on the above subject. Two photographs were shown which were obtained in the interior of a Crookes tube in a little frame of hard rubber. This frame contained four sheets of sensitive paper and two sheets of Schleussner film of bromide of silver, and was covered first with a sheet of aluminum, 0.33 millimetre thick, and finally by a piece of cardboard, 0.86 millimetre thick. On top of the sensitized layer, but under the cover, a cross of copper was placed. In the first experiment a part of the copper was covered by a sheet of platinum 0.32 millimetre thick, but in the other experiment the cross was left free and in the bottom

[1] London "Electrician."

[2] See page 591 this issue.

of the frame a little shield of zinc was placed. The Crookes tube was of cylindrical form and was composed of two pieces, the parts being fitted together by being ground on emery. The tube carried in one portion the anode in the form of a large ring and the cathode in the form of a spherical mirror, while the other only contained the frame, 29 millimetres in diameter and 11 millimetres high, which was exposed directly to the influence of the cathode rays.

During the operation a Sprengel mercury column was used to examine the degree of the vacuum, when the strong fluorescence of the walls of the glass was obtained. The discharge of the Ruhmkorff coil was made of short duration, from three seconds to two or three minutes, because tne tube quickly became filled with a white glimmer and then the fluorescence became feeble or even disappeared. It was only necessary, however, to pass a few drops of mercury through the pump before commencing the discharge again.

Twelve photographs were obtained. It appears that the cathode rays in the interior of the Crookes tubes have one of the properties of the Röntgen rays, for they penetrated the aluminum, the cardboard, the sensitive paper and the film, but they were arrested by the platinum and the copper.

It is proposed to continue these experiments in the hope of distinguishing between the properties of these two kinds of rays.

PHOTOGRAPHS OF INCANDESCENT LAMP FILAMENTS.

I AM not aware, writes Mr. R. D. Cassells, in the London "Electrician," that experiments have been made to show whether or not certain substances—which in the solid condition at ordinary temperatures are non-transmitters of light—become transmitters of light by increase of temperature, say, to incandescence. Inclosed is a photograph of an incandescent lamp filament, taken by me a few days ago, and photographed by its own light.

The appearance is that where the filament crosses itself in

PHOTOGRAPH OF INCANDESCENT LAMP FILAMENT.

the photo there is a brighter light given out. This would tend to show that the carbon became a transmitter of light when incandescent, so that the light from the rear portion of the filament penetrated the near portion, thus increasing the brilliancy at the points of apparent intersection of the filament with itself. The lamp was run off a 100-volt continuous-current circuit.

FLUOROSCOPE ODDITIES.

Mr. Edison has of late been in receipt of bushels of letters relative to the use of the fluoroscope, and many of them are of an amusing or pathetic nature. In one case, his correspondent wrote from Pottstown, Pa., as follows: "Will you please send me one pound of X-rays, and bill, as soon as possible." In another instance a man with weak sight asked whether he could send his spectacles to Mr. Edison and have them so "fixed up" that they would enable the wearer to see better by means of utilizing the X-rays.

AN X-RAY STUDIO.

Mr. M. F. Martin has opened an X-ray studio at 110 East Twenty-sixth street, where pictures of the interior human structure, etc., will be taken. The consultation hours are from 1 to 2 and 5 to 6. A lady assistant is in attendance.

LETTERS TO THE EDITOR.

MR. FALK ISSUES A CHALLENGE.

IN your issue of May 13, you published a letter written by a man whose identity is well known to me, and, in justice to myself and to the public, I would beg to say that I have never seen in print a more diabolical falsehood. The statements of this man cannot be substantiated.

This man called at my home some six weeks ago, April 13, I believe, and requested me to photograph his hand, to which I consented. I procured the plate. This man then produced a common cardboard box, which he placed at one end of the plateholder which contained the plate. He then placed his hand on the other end of the holder. He then announced that he was ready. I then turned the current on to my tube. The instant I did this he crossed his third and fourth fingers. Can this informant of yours deny that when the plate was developed (which was done in his presence) that the image on the negative showed his hand as he placed it, also the outline of the box which he had placed on the holder in a peculiar position.

The claim that there were some articles in the box is an untruth, for when tnis man picked up this box after the exposure he accidentally let it fall, and it made no other sound than of an empty box. He goes on to say that as I claimed that I used wet plates he opened the holder in the dark and found that I had only an ordinary dry plate. This statement is not worth the paper it is written on, and if you will send a representative of yours to my place, I will prove to him that I do just as I claim, and I defy this man to prove any of the statements he has made in that letter to you, which you have published.

I have challenged this man through the public press (see clippings enclosed), but for reasons best known to himself he did not call to make the test. I will put up $1,000 to every $500 of his that I will photograph his brain in any position he may choose, the position to be unknown to me until he places his head on the plateholder. Let him take this up or shut up.

I intend publishing to the world my method of photographing the brain on the first day of January, 1897. The world will be able then to judge whether I am a fraud or not. This man claims that it is impossible to photograph the brain. He says this because he cannot do it, but it is no reason why others cannot do so.

I hope you will do me the justice of publishing this letter, with one of the clippings of the "Times-Democrat," where I make the offer of turning over to a committee my whole apparatus, with or without my presence.

H. L. FALK,
President X-Ray Shadowgraph Co.

New Orleans, La., May 18, 1896.

As Mr. Falk requests the publication of his letter, as a matter of justice to him, we have complied with his desire. It is needless to say that, notwithstanding Mr. Falk's assertions, our faith in the ability and trustworthiness of the gentleman who made the investigation for us is not shaken in the least. We may add that we have more recently received from Mr. Falk additional X-ray photographs, among them one showing the muscles and arteries of the foot, while another, according to Mr. Falk, shows the kidneys and contiguous organs of Mrs. E. Burke Collins, "the popular authoress of New Orleans." Neither of these photographs shows the slightest trace of bony structure. EDS. E. E.

THE ALUMINUM FLUOROSCOPE.

In the current issue of your review I notice a communication from Mr. H. V. Parsell, Jr., on fluoroscopes.

The irregular luminosity he describes is due solely to the dilation of the pupil of the eye, which, in the darkness of the fluoroscope, is dilated to its utmost. With a view to ascertain the value of his assertion, I have carefully tested both the Aylesworth-Jackson and the aluminum instruments (the latter presented to me by Mr. J. A. Leroy), and I find the aluminum screen to be much more effective, giving greater fluorescence to the transparent, and supershadows in the opaque parts; while the outline of the visible object is sharp and clear. This is certainly what we have sought for, and, as we become more clairvoyant with every revolution of the earth I hope your observing correspondent will take another good, long look through the aluminum.

PROFESSOR O'REILLY,
306 East Eleventh street.

New York City, May 22, 1896.

CONTENTS.

THE SUCCESS OF THE EXPOSITION.

THERE were probably very few who, when the exposition started, had any idea that it would prove such a brilliant success. That it might make a moderate hit, was the expectation of many. Yet even they had their opinions shaken by the pessimistic utterances of those who didn't believe in the success of a technical show anyhow, and who pointed with painful persistence to the undeniable fact that the theatrical and show season in New York this past winter was one of the worst on record. But all hopes and fears alike have vanished before the remarkable and overwhelming demonstration of public interest and popularity, and the exposition thus goes into history as one of the city's red-letter events.

The Exposition Company deserve much credit for their public spirit, and have come out of a severe ordeal with flying colors. Some things might have been better done; other things were better left undone, and yet other things might have been attempted. Granting this, which would be true of any like enterprise, the net result remains in a successful show which has already stimulated the art in a striking manner. Outside the guarantee to the Association of $2,000 for its name and prestige, the company has been run to make money, and not like so many other electrical schemes, to lose it, but the management was very liberal in many ways. Realizing that commercial exhibits alone, however good, would not attract crowds, and desirous that the crowds should come to see those commercial exhibits, the management at the very outset spent large sums of money in building up features of interest and attractiveness, and in giving the show as a whole the setting of ornament and beauty that elicited praise from every visitor.

It is not to be gainsaid that the exposition owed much to Mr. Edison, and that its ability to draw the public was settled the day he generously consented to co-operate. And yet we feel that even he must have been repaid when, upon his first real public appearance, the night of the message around the world, the public yielded to its enthusiastic and wild outburst of applause and would not be stilled. Equally pleasing to him, no doubt, must be the knowledge that by his skill and energy the thousands of visitors were enabled, by means of the fluoroscope exhibit, to test the value of Röntgen's great discovery. The long lines of waiting hundreds were good proof of the way in which to-day a new scientific fact can touch the popular imagination. If there is to be hero worship, it is a good thing for the business to have some of it expended on an electrical inventor; and Mr. Edison has certainly never got so near to the public heart as he did during the past memorable month.

Others, too, with not less public spirit, have given freely of their time and thought and labor, and it is the barest justice to mention Mr. Luther Stieringer, Mr. Max Osterberg, Dr. Park Benjamin, Mr. E. L. Morse and Mr. W. J. Hammer, as loyal, indefatigable workers contributing to achieve so wonderful a success. No exposition could be made a "go" without such effort, and on this occasion it was given without stint.

We have made it our business to inquire among the exhibitors as to how they feel about the results of the show, and have been struck by their unanimity. Satisfaction is a mild word to apply to the feelings of many who have sold large quantities of goods and apparatus and have made hosts of new friends and customers. Several exhibits were sold in block, as they stood, and there was hardly a booth that was not the scene, every night, of inquiries for prices and applications for goods, or agencies. And yet the work was largely educational, for the crowds that are not yet in touch with the art went away deeply impressed with the desirability of enjoying the things they saw and determined to get them in the house, office, store or factory as soon as possible. It is by creating this favorable atmosphere that a market is built up and extended; and New York, with its territory, is a grand arena for such effort at any time. The remark was constantly made at the show that the crowds were largely made up of the very people it was needful to reach, namely, those who represent the wealth, culture, refinement and education of the city. Superintendent Nathan says he had never seen a show where there was such a general wearing of evening dress by the visitors, and that shrewd little comment tells the whole story.

As to the stimulus given to the art, that is as remarkable as the good derived by the industry, and we do not hesitate to say that the National Electrical Exposition of 1896 has carved a deep notch in electrical history. There was, to begin with, the transmission of energy from Niagara, nearly 500 miles, to the little Tesla motor. There was the popular exploitation by Mr. Edison of the Röntgen ray phenomenon. There was the beginning of commercial vacuum tube lighting in the extraordinarily attractive and successful exhibit of Mr. Moore. There was the clever capturing by long distance telephone of the roar of the Niagara cataract and its use as a feature of a great show hundreds of miles away. There was the convincing demonstration of the ease with which aerial motors can haul boats on the Erie Canal. There was the emphatic success of the enclosed arc, and the ocular demonstration of the fact that the storage battery has arrived. There was the proof that the happy union of the electric motor with the tools and apparatus it has to drive is beginning to make a profound impression on all departments of mechanics and engineering. There was a splendid display of beautiful and perfect direct connected dynamos and engines in the generating department, and in the steam section there was one of the most instructive groupings of apparatus and advanced methods that it is possible to imagine. There was, moreover, one of the most interesting of collections of educational and experimental apparatus, including that of Professor Elihu Thomson and Dr. R. Ogden Doremus, as well as that from half a dozen universities and colleges. And when we have enumerated all this, we have left many things unmentioned, any one of which has served, at this great exposition, as a new starting point for endeavor and achievement.

METHODS OF CURRENT CHARGING.

As time passes, methods and apparatus which have proved inefficient in electric light and power distribution are being superseded by more modern devices, and we believe that on the whole American central stations are gradually improving in efficiency of internal operation as well as in those features of general administration in which the distributing company comes in direct contact with the public. But while these improvements have been going on, it would seem that in one very essential feature of administration there has been little progress made even during the last ten years. We refer to the system of charging for current to consumers. In the early days the contract or flat rate was considered adequate, and not its least advantage was its simplicity; but the operating companies soon became aware of the fact that in cases where no fixed number of lights were used for a definite period each day, the contract was a double-edged sword, and that the assumed economic habits of the consumer were but a slender rod to lean on. But far more important, from the standpoint of enlarged station loads, was the deterrent effect which the flat rate exercised on the minds of the public, who preferred to pay only for what they were actually getting. The meter, which, from the beginning, was so strenuously advocated by Mr. Edison, finally won the day, and it is safe to say that no station to-day making any pretence to good management is operating without meters. While a distinct advance is, therefore, noticeable, in this direction, there still remains considerable work to be done to raise the meter system to its highest point of usefulness. It is evident that current for certain kinds of work can be furnished at less rates than for others, that large consumers can be furnished at less cost than small ones, etc., and these conditions have been generally sought to be met by a graded series of discounts. No fault can be found with the basic principle here involved, but it is a question whether its application is generally carried out in a manner best calculated, first, to guard the interest of the central station, and, secondly, with equity to the consumers. It is this question which Mr. A. J. Farnsworth discusses elsewhere in this issue in a manner well calculated to bring out the points involved. We do not believe that any system can be devised that would be perfect enough to embrace all the various conditions that arise in actual practice; but the system advocated by Mr. Farnsworth has the merit of simplicity and unquestioned fairness, up to the limits which it embraces. A perfect system of charging would have to take account not only of the actual energy consumed by the customer, but also of the maximum drawn at any one time, and of similar conditions which have a direct influence on the power equipment at the station. The Wright maximum current indicator has been introduced in connection with a number of English central stations, and with apparent good results. Violent load fluctuations are a source not only of strain on the system, but also of inefficiency in the working apparatus at the central stations, and as such should be taken cognizance of in charging for current. Another point to be considered in charging, which is generally lost sight of, is the time of day at which the consumer draws current. We are well aware that extra rebates are generally allowed to large consumers of current during light load hours, but Mr. Farnsworth has done well to point out that under certain conditions it may be profitable to take on customers at cost or less in order to bring up the load to the point of greatest efficiency for the station apparatus. This particular point is all the more worthy of attention in American central stations, which, with a few exceptions, are still devoid of storage batteries. With the lapse of time, however, it is fair to assume that it will cut less of a figure. Mr. Farnsworth's system of charging, suggested by him in this issue, may well form the text for a general discussion of the subject, and we shall be glad to open our columns to communications with that end in view.

ELECTRIC AND COMPRESSED AIR TRANSMISSION.

The relative advantages and limitations of power transmission by compressed air, as compared with that by electricity, are too well known to require further elucidation at this late day, forming, as they do, the subject of investigations and papers by many able engineers. It is with surprise, therefore, that we note some of the statements contained in a paper by Mr. A. De W. Foote, member of the American Society of Civil Engineers, which appears in the society's "Proceedings" for May. This paper describes the system of compressed air transmission just completed at the North Star Mining Company, Grass Valley, Cal., where between 200 and 300 horsepower are transmitted for a distance of about 1,000 feet. Mr. Foote tells us that electricity naturally suggested itself first as the means to be employed; but visits to mines in operation and careful study and investigation of electrical appliances for underground work, especially pumping, finally decided him in favor of compressed air. His statement would mean primarily that the electrical mining apparatus offered at the present time is not up to the requirements. This is a question involving design, and if such be the case we have little fear that electrical manufacturers can work out their own salvation. But Mr. Foote gives some figures as to the results obtained by the compressed air plant which show that of 304 theoretical horsepower in the water used in the power house, 203 horse-power is actually obtained at the mines, to which must be added the cost of reheating, $3 per day. The efficiency of compression and transmission from the theoretical power of water to and through the motors, including cost of reheating expressed in water power, is put at 61.6 per cent. It is a pity that the author did not give more definite facts and figures to substantiate his assertion of the superiority of compressed air in the present instance, where neither lighting nor railway work is involved, but, assuming his judgment to have been correct, he takes a bold stand indeed when he asserts that, were it 20 miles instead of 1,000 feet, air will prove cheaper in first cost, higher in efficiency, less liable to accident, and less expensive to operate and maintain. To find such an assertion in such a place seems to us to call for some explanation on the part of the author, as he directly challenges the ability and judgment of some of the most prominent engineers of the day. We need only cite Niagara as a case in point. This plant was designed from the very start for power transmission exclusively, lighting work being left entirely out of consideration; and yet an international commission after thoroughly considering all suggested methods of power transmission selected electricity for even the local distribution about Niagara, involving distances scarcely exceeding one and a half miles. But when the author speaks of 20-mile compressed air transmissions as more economical than electric transmission, he sets at naught the experience gained in the last ten years in hundreds of installations. It is quite possible that in the particular case, Mr. Foote mentions, compressed air possessed advantages over electricity, but the broad statement above quoted ought to be backed up by facts and figures—which we think will be hard to produce.

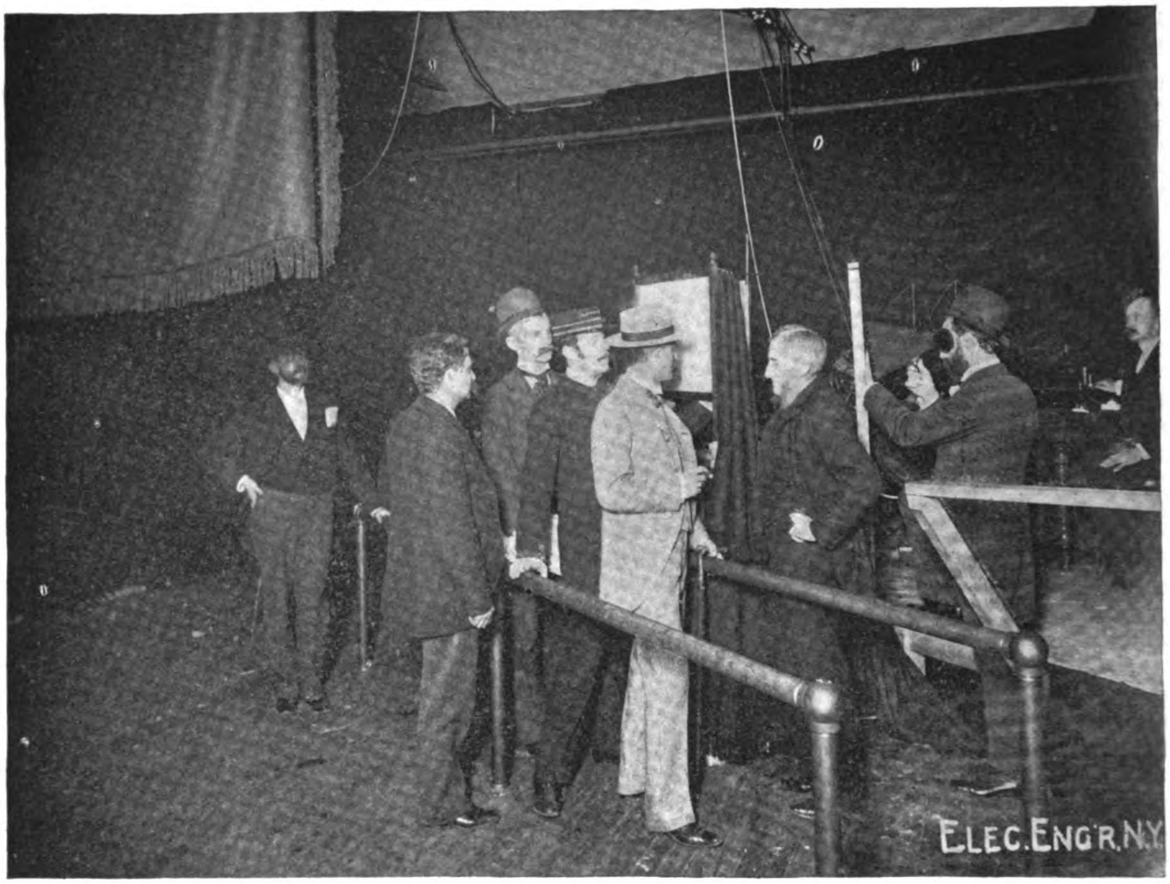
Exhibition Notes—IV.

THE EDISON FLUOROSCOPE EXHIBIT.

WITHOUT doubt, one of the greatest attractions of the wonderful electrical show was the apparatus generously placed at the disposal of the management by Mr. Edison, to enable the public to examine its own anatomy by means of the X-rays. Only those who are at all familiar with the apparatus have any idea of the work and planning that had to be done in order to render successful the task of indulging the curiosity of thousands of people nightly with a personal test of one of the most delicate experiments and most striking discoveries of the age. Mr. Edison early became deeply interested in the trial and himself went through arduous work to get the result that no amount of money could have induced him to undertake. As already stated, it was at first the intention of arranging three or four sets of apparatus, by means of which, using the hand Edison fluoroscope, several people at once could look at their hands. This was experimented with for some time, but it was soon found that it would require a very large expert staff to run such an exhibit, while the risk of breakage of fluoroscopes, failure of tubes, etc., would be multiplied. Such a large staff could not be spared from the laboratory. Work then settled down to the building of a large Edison fluoroscope screen, on which one exhibitor should continuously display his whole arm, but this had its difficulties, and it was also realized that everybody, as a general thing, wanted to see his own bones and not those of some one else.

All this was preliminary to the location and fitting up of the Fluoroscope Exhibit Room, itself quite a distinct and difficult problem, for it involved not only the question of ingress and egress for a steadily flowing crowd, but the choice of the best means for getting the result at the screen. The fact that the thing has proved such an emphatic success is due in no small degree to the expert advice and active personal work of Mr. Luther Stieringer, whom Mr. Edison early called into consultation and to whom he committed the care and operation of the exhibit as a whole. It was decided to locate the room on the third floor, or annex, at the west end, in the rear of the Practical Electrical Laboratory, in such a way that the public could aproach by the long galleries and discharge very appropriately into the restaurant, where it could sit and talk over its experiences.

The room itself was solidly constructed of wood, around some of the iron pillars, the exterior and interior being heavily draped in black, both to exclude light and to accustom the eye to the state in which it would best catch the effect of the Röntgen ray. In this manner a chamber capable of accommodating about 100 people was secured, and the fluoroscope screen, with Crookes tube and Ruhmkorff coil, under the watchful eye of the operator, was placed on the high platform built expressly for the purpose. The visitor entering circuitously, after reading sundry signs instructing him or her to slip a coin or key in the glove, etc., was ushered into the Egyptian darkness, lit only by two blood-red incandescent lamps, the rays of which were intercepted from the fluoroscope by pendant palls of black. Immediately along the edge of the platform ran a stout wooden rail, and outside this was a massive iron rail with stanchions forming an alley through which the endless line of people passed. On coming to the fluoroscope, the visitor was quietly told to slip his hand underneath the supports and press it against the screen palm side toward the eyes, and fingers close together. The hand was thus between the Crookes tube and the screen, and the structure of the hand was immediately visible. So many of the visitors were clumsy, it was early found necessary to stiffen the supports of the fluoroscope and interpose a stout hard rubber slotted shield between the tube and the screen. Even then many people behaved as though they wanted to carry away the whole arrangement on their arms as a souvenir. But the management was excellent, and what with the police outside and the guiding attendants within, things went smoothly every night, and each of some three or four thousand people had a momentary glimpse of their own bony structure —for the first and last time in this life. Many of them flinched when they got in front of the screen and refused to look, either at their own bones or anybody else's. Some crossed themselves devoutly after a fearsome glance, although, as a matter of fact, the great majority came out all smiles and



THE EDISON X-RAY AND FLUOROSCOPE CHAMBER AT THE EXPOSITION.

laughter. No burlesque could be more provocative of merriment than this gloomy room, out of which the visitors emerged very much "stuck on themselves," and poking good-humored fun at the queer look of their friends' bones. The crowd was in reality delighted to find the show neither horrid nor awful. but tickling and mirth-making. There were several who had injuries and deformities. These were sifted out for further study and for experts like Dr. W. J. Morton. The funny remarks made would fill a new volume of Joe Miller.

The mechanism for operating the tubes and screen was placed in an adjoining little room just off the platform and fitted up for the occasion, with a bank of lamps, Root blower for the interrupter, motor fans, etc. Here Mr. Edison was often to be found, and the little "green room," as it came to be called, was the scene of many memorable gatherings of celebrities.

Mr. Stieringer supervised everything and watched every detail, even to such points as placing several fan motors in the dark room and on the stage to keep the crowd and the exhibitors cool. The staff of the exhibit consisted of Messrs. Fred. Ott, C. Brown and C. Dally, three of Mr. Edison's best experts from the "lab." who were at first not a little surprised and amused at their ordeal as showmen, but who soon took to the new occupation with much zest, got lots of fun out of it, as well as hard work, and made their important share in it a brilliant success. It is needless to say that constant care and delicate manipulation on their part were essential, and that at first a daily report of unexpected conditions, to Mr. Edison, was necessary. A Crookes tube is a balky, iniquitous thing, which develops an amazing amount of human depravity and perversity upon a very small margin of vacuum; and to those who watched the performance it was a pretty sight to see how deftly the old tubes were coaxed up to their work or replaced if they gave out, without any holding back of that long, pushing procession of inquisitive New Yorkers eager to be "X-rayed."

In the photograph here shown, the only one for which permission has been granted, Mr. Stieringer is seen at the right taking a shot at the tube with the Edison hand fluoroscope. Mr. Brown, from the laboratory, is at his left. Outside the iron rail stands Mr. Ott. At the extreme right of the picture is Mr. Dally, at the induction coil.

The readiness with which some of the visitors have cried out that the thing was not genuine has had its curious and amusing side. One night a gentleman declined to go inside the rail and said that the screen was only ground glass with a light behind it, an arrangement with which anybody would cast a shadow. It is well known that the range of vision has a good deal to do with the clearness with which the Röntgen ray effect can be seen; and as the fluoroscope is protected by glass the inference was natural to a suspicious mind. Mr. Stieringer seized the man, however, and politely insisted on placing him within the rail, his hand upon the screen and his nose close to the glass. The big bones of the sceptic loomed up with startling vividness, and their owner, with the involuntary ejaculation, "Oh! My God," hastened away with the realizing sense of what modern science could do to confirm the predictions of ancient Scripture as to exposing hidden things.

It is worthy of note before closing this article that Mr. Edison himself operated the fluoroscope exhibit one of the early evenings, to see whether it was all right. He sat by the switch at the coil, and there in the darkness went quietly to work. Perhaps one or two people in the crowd recognized the face and figure when their eyes had become accustomed to the gloom, but it is safe to say that the vast majority had not the faintest idea they were within hand-shaking range of the man who to them represents more than any other the great modern arts of electricity.

THE TELEPHONE AT THE EXPOSITION.

THE exhibit of the Metropolitan Telephone Company was a good illustration of the substantial manner in which the New York telephone service is carried on and of the highly finished appliances used in the telephone service. Realizing the impossibility of adequately representing in an exhibit for a short period the elaborate switchboards and complicated equipment of its central offices, the company decided to install in the exhibition a miniature exchange, placing standard long-distance instruments in the spaces of many exhibitors and generously offering them the free use of the New York service. This was an accommodation that was highly appreciated by the exhibitors, who were thus able to keep constantly in touch with their respective headquarters in and out of the city.

In the space reserved by it the Metropolitan Company placed a small switchboard for operating the exhibitors' telephone lines and four silence booths of various patterns equipped with the different types of standard long distance telephone sets that are supplied to New York subscribers. These are the regular wall set, the desk cabinet set, the wall cabinet set and the desk stand set, all highly finished, substantial apparatus, and forming an interesting demonstration of the enterprise shown in making the subscriber's station harmonize with its surroundings and be an ornamental as well as useful part of the furniture of an office or private apartment.

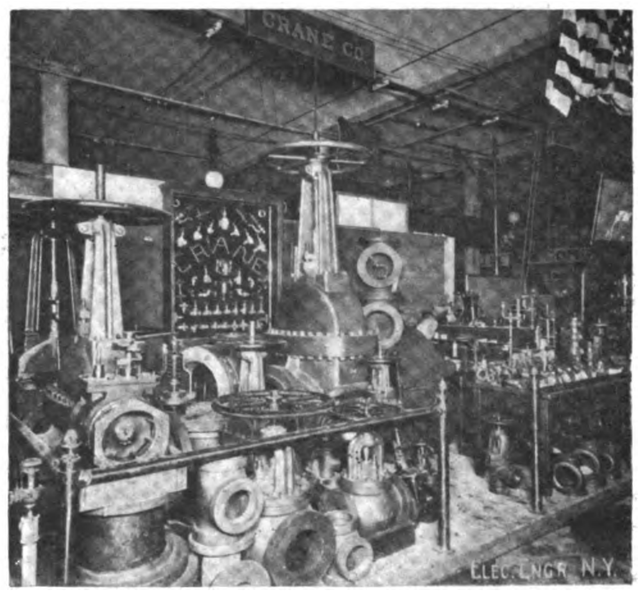
The little switchboard, with its graceful and expert operator, was a constant object of interest to the crowds at the exhibition. It gave them just an inkling of the working of a telephone central, and the rapid play of annunciator shutters, plugs and cords was watched by an absorbed group all day long. If a portion of one of the large multiple switchboards from any one of the dozen exchanges, with an operator doing her daily work putting up connections at the rate of several hundred an hour, could have been shown, it would be the most exciting exhibit in the whole show. The exhibition switchboard had connected to it all the lines to the exhibitors' spaces, those of the four pay-station booths and a number of trunk lines running to the exchange in the Telephone Building on West Thirty-eighth street. Connections were made on it between the exhibitors who wanted to talk with each other and also between any station in the exhibition and any station in the New York system. As might be expected the service was in incessant demand, and the operator and her little switchboard were constantly at work—to the delight of many who probably never knew before what happened at "Central" when they rang their bell and called for a number.

The Metropolitan Company's exhibit proper showed effectively the arrangement of a large public telephone station of which every important hotel in New York has one more or less like it. The company has twelve exchanges in New York, which serve over 15,000 telephones, of which about 1,200 are public stations scattered all over the city. Nearly twice this number are in private residences, this use of the telephone having largely increased during the past year or two in response to the inducements offered by the message rate system, which enables a moderate amount of telephone service to be had at a very low cost.

The exhibit was under the charge of Mr. Brewster. It should be added that the connections for listening to the roar of Niagara were also made through the exhibit and by its staff.

INTERESTING EXHIBIT OF THE CRANE CO.

AN interesting exhibit was made in the Generating Department, on the ground floor, by the well-known Crane Company, of their steam valves and other specialties, in charge of Mr. Fred Mitchell, whose active and intelligent



THE CRANE CO.'S EXHIBIT.

representation of their product made a favorable impression on the many inquirers for data and prices. A view of the exhibit is given herewith. The exhibit consisted of Crane's

extra heavy gate globe and angle valves, and extra heavy fittings for same, from 2½ inches up to 24 inches, inclusive, all having been tested to 800 lbs. pressure and guaranteed to stand a working pressure of 250 lbs. Some idea of the bigness of the work turned out by the company may be formed from the fact that the valve seen in the exhibit weighs no less than 6,770 lbs. These extra heavy valves have been used by the New York Edison Company in their various plants, and also in the two new plants of the West End Railway Company of Boston. Another line shown consisted of Crane's hard metal globe and angle valves, with renewable metallic discs. In addition to these, the exhibit comprised Crane's patent cup check valves, noiseless back pressure valves, pop safety valves, water relief valves, low water alarm, unions with metallic gaskets, Crane's cement, the "Mocking Bird" steam whistles, standard indicator, etc. All the goods shown were of the highest grade of workmanship, while their efficiency and economy is an old story to steam and electrical engineers.

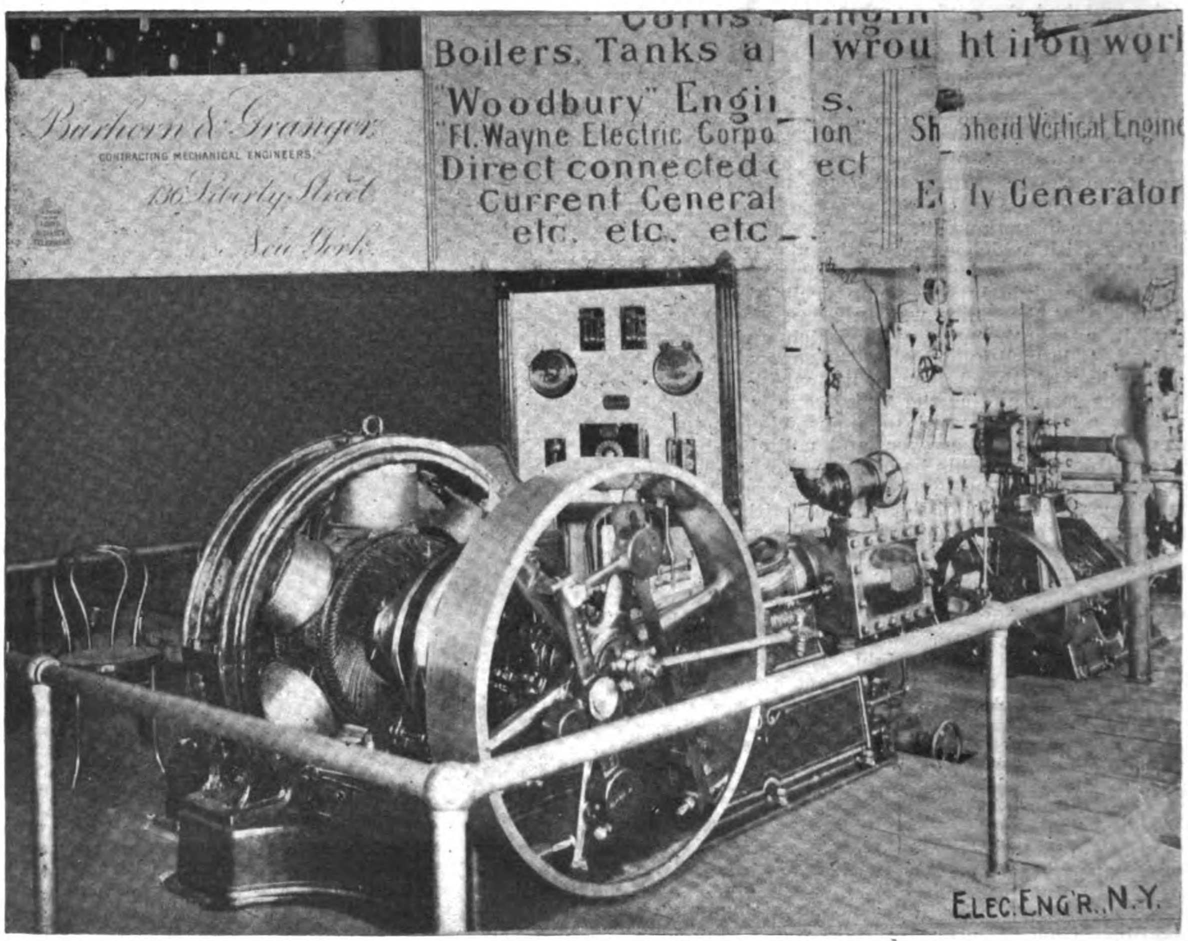
THE BURHORN & GRANGER EXHIBIT.

ONE of the engines that has attracted much attention and favorable comment by engineers visiting the Electrical Exposition is the "Woodbury," exhibited by Messrs. Burhorn & Granger, of No. 136 Liberty street, New York. Not only was the engine seen in operation, running lights and motors continuously, but the design and construction of all its parts were scarring of surfaces, and keeping valve stem tight, even after the engine has been in operation for years, and thereby making the engine most economical in the use of steam; all these were perfectly shown and thoroughly apparent.

The regulation in speed by the governor, under varying loads and steam pressures, was actually shown. A Schaeffer & Budenberg recording tachometer was used to show the speed of the engine at all times, and the entire load of the engine was thrown on and off instantaneously by means of the main dynamo switch. The results obtained were remarkable and excited the admiration of engineers, who watched the test with unusual interest. Under the severest conditions the maximum variation in speed, with all load thrown off or on, was two revolutions, and within a second the governor brought the engine back to its standard speed without racing or vibration. The engine speed being 300 revolutions per minute, the regulation was considerably within 1 per cent.

The Shepherd governor, used exclusively on all Woodbury engines, consists of only two parts, namely, a main arm, containing an eccentric pin; a counterbalance arm, and a flat spring, opposing the governor. The main governor bearing is a roller bearing, and a knife-edge of hardened steel connects the two arms. No lubrication is necessary for the governor, and the latter being entirely frictionless and balanced within itself and in combination with the perfectly balanced valve, it was shown why this regulation should be as perfect as it is.

The engine was not bolted to its foundation, being leveled on six wedges, perfectly free, and ran 300 revolutions per min-



THE WOODBURY ENGINE IN BURHORN & GRANGER'S EXHIBIT.

clearly shown. A cylinder of a standard engine, cut through its center longitudinally, was exhibited, showing clearly the multiple-ported valve, with its quadruple admission and double exhaust ports; the arrangement of balance plate, whereby the perfect freedom from pressure on the valve is obtained, even with the engine running under 125 pounds steam pressure; the easy and absolute freedom from wrecking, due to water in the engine cylinder, and the means of lubricating the valve surfaces before starting up engine, preventing binding and

ute; with a full load coins were balanced on edge on the cross head guides, and water in a glass set on the guides showed not the slightest sign of ripple, showing the remarkably perfect balance in all its parts. With all the surrounding machinery at rest, the "Woodbury" was kept in motion, and the noiselessness of operation was demonstrated. The engine is a 9 x 12 inch, direct connected to a 25 kilowatt Ft. Wayne direct-current generator.

Besides the "Woodbury," Burhorn & Granger showed a 6 x 6

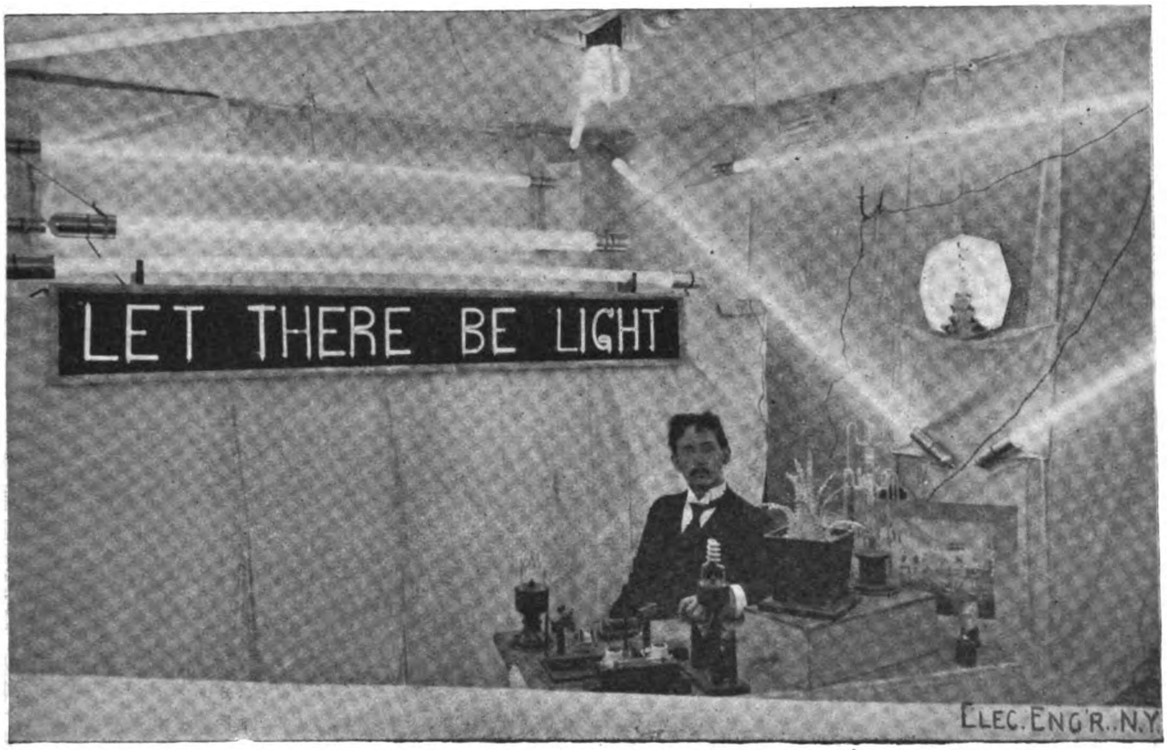
inch Shepherd vertical engine of 18 horse-power, running at 500 revolutions per minute, and connected direct to a 10 kilowatt Eddy generator. This engine has practically the same valve and governor as the "Woodbury," and the regulation is shown to be as close. The engine runs entirely free of noise and vibration, and formed a most unique and instructive exhibit. The entire outfit is to be put to continuous duty at the Metropolitan Apartment House, Eighty-eighth street and Western Boulevard, to carry the day load. Burhorn & Granger are to be congratulated on the completeness and excellence of their exhibit and without doubt, the showing of their engines will leave a decided and favorable impression with the many engineers and others who visited the exhibit.

THE MOORE "CHAMBER OF LIGHT" AT THE ELECTRICAL EXPOSITION.

ONE of the features of the exposition which attracted a stream of visitors, second to no other exhibit, was the Moore "Chamber of Light." Tucked away in a corner at the foot of the gallery stairway, and occupying a space about 10 feet by 12 feet, the Moore exhibit served to attract an average of over 2,500 persons each night. The space allotted to Mr. Moore was economized in the highest degree. The vibrators and the person in charge of the switches were situated behind a screen placed 30 inches from the wall and before which Mr. Moore is seen seated in the accompanying engraving. Running diagonally across one corner of the space a counter was erected, which formed a barrier separating the visitors from the working apparatus. The public was admitted through curtains, a dozen at a time, and each batch was allowed to remain about a minute, and then the fact that their presence was no longer desired was gently conveyed to them by turning out the lights.

The Chamber of Light was lit by about 15 tubes and various ornamental designs, and the sign, "Let There Be Light," which was used on the occasion of the A. I. E. E. meeting and the lecture before the N. E. L. A.

The photograph from which the accompanying engraving was made was taken with an F 32 diaphragm with an exposure of two minutes. A photograph taken with an exposure of 30 seconds showed up almost, if not quite, as well as the other.



THE MOORE CHAMBER OF LIGHT AT THE ELECTRICAL EXPOSITION. TAKEN WITH A TWO-MINUTES' EXPOSURE.

QUEEN & CO., the well-known old house of Philadelphia, were among the leading exhibitors in the annex gallery, where they had a beautiful line of the electrical instruments they handle. It attracted much attention.

THE MORRIS & SALOM ELECTRIC CARRIAGE.

In connection with the exhibit of the Electric Storage Battery Company, the Morris & Salom electric 4-seated carriage was put on view at the Exposition, but it was not treated by any means as a still exhibit. On the contrary, much to the regret of a large number of visitors, who hunted for it, but to the delight of all out-door New York, it was taken into the streets, and put through its paces in a very matter-of-fact manner. Trips were made with it over all the important streets, and many persons had an opportunity of proving for themselves how easily it can be steered and started or stopped. After such a demonstration, New Yorkers will not be very sceptical as to the success of electric carriages.

A SUPPER TO THE EXPOSITION CO.

THAT the exhibitors at the National Electrical Exposition should tender the Exposition Company a supper on the closing night, as an expression of good will, is but another of the many unique features associated with that remarkable affair. The "love feast," organized with much skill and energy by Messrs. G. Stanmore, J. T. Outwater and Frank Harrington, was held at the Murray Hill Hotel, began about midnight and lasted until nearly half-past 2. The Exposition Company was represented by President Smith and by Messrs. Baker, Seely, Peck, Stump, Godfrey, Porter, Nathan and Stadelman. The exhibitors, who were ably represented in every respect, placed Colonel Rogers, of the Brush Electric Company, in the chair, and after supper a few brief congratulatory speeches were exchanged, the speakers being Messrs. Rogers, Smith, Godfrey, Baker, Seely, A. Williams, T. C. Martin, E. P. Morris, Price, Lieb, and McKinney. The supper closed with a rising toast and vote of thanks to Mr. T. A. Edison for the generous manner in which he had helped to make the exposition such a wonderful success, and the names of the other electrical leaders, who had contributed to the art and the success of the show, were also called and applauded.

A COMMENT ON BRUSH DYNAMOS.

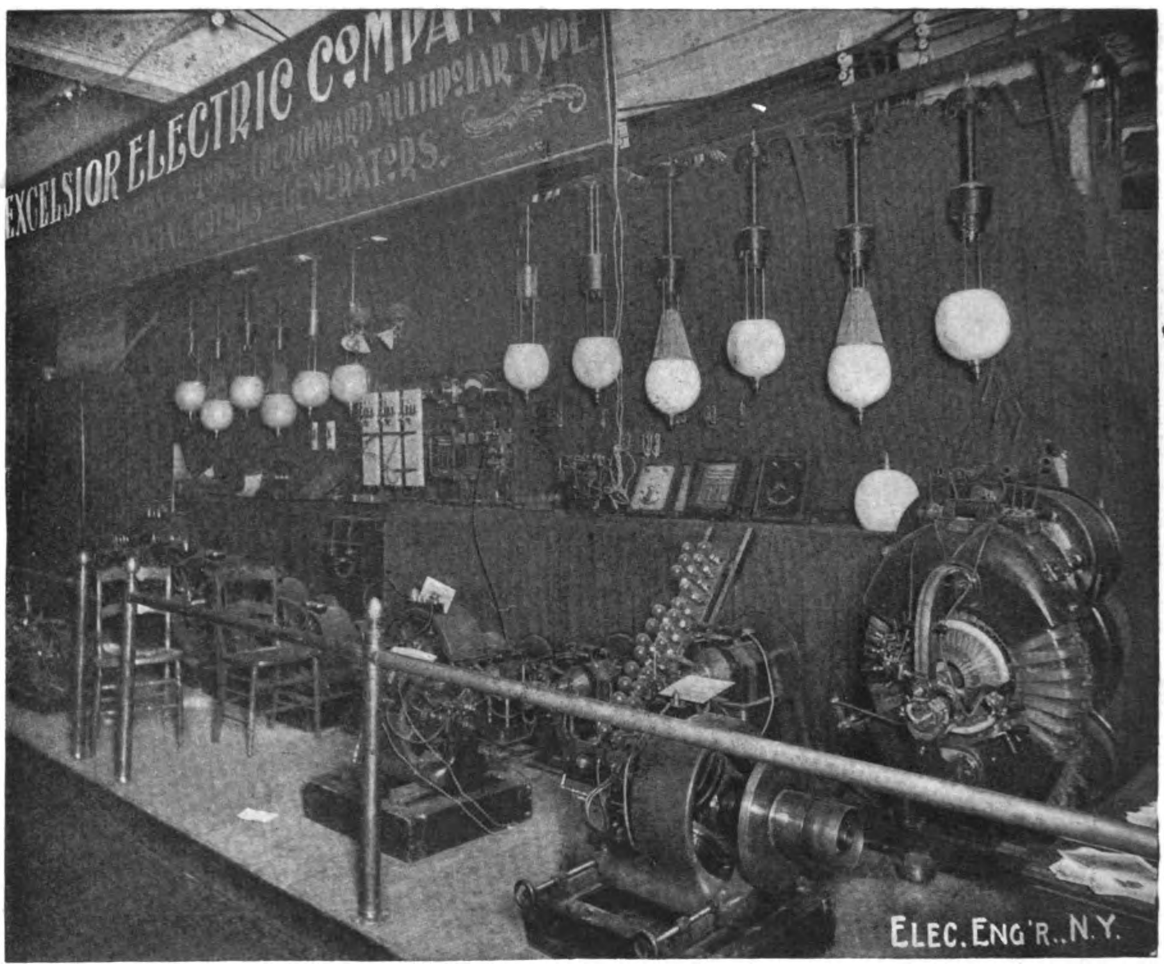
"Sold, but we have others," appeared on a card on one of the large Brush arc light machines that formed part of the exhibit of the Brush Electric Company, of Cleveland. Was any further commentary necessary that electric exhibitions are not only interesting but beneficial and remunerative?

THE FINE EXHIBIT OF THE EXCELSIOR ELECTRIC CO.

ONE of the most striking and creditable exhibits at the National Electrical Exposition was that of the old, well-known and ever progressive Excelsior Electric Company, who, in their neatly arranged space, just off the main floor, grouped together an excellent display of their apparatus for current generation and for lighting and power.

Among the leading features of the exhibit were the latest Hochhausen type of arc machine, capable of carrying 125 lights, and a full line of the familiar and successful Excelsior arc motors ranging from ½ up to 10 horse-power. The leading points about the "big little" arc lighter for 125 lamps are:

(1) Comparatively low shaft speed. This, together with the machine being bipolar, reduces the losses otherwise experienced due to eddy currents and hysteresis. (2) The armature can be taken out and replaced without disconnecting a single wire, by simply loosening two catches. A station equipped with these machines does not need an expensive traveling crane to take out and replace the armatures. (3) Being bipolar and with only one path for the magnetism to flow in, the regulation is absolutely perfect, even under the most exacting conditions, such as a motor load, and in case of an open circuit there will be no perceptible rise in voltage. (4) The regulating motor being directly geared to the rocker arm, the regulation is instantaneous.



THE EXCELSIOR ELECTRIC COMPANY'S EXHIBIT.

Together with this machine was shown a complete line of arc lamps, clutch, rack focusing, low single and double carbon lamps, marble switchboards, lightning arresters, ammeters and wall controllers. This machine was running every night of the exposition on comparatively a short circuit, viz., six lamps. The heating, even under such a severe test, was only just perceptible.

Another section of the exhibit comprised a line of Churchward multipolar generators and motors ranging from 20 lights up to 650, and 1½ horse-power up to 50 horse-power. These machines possess all the features desirable in apparatus of that class, and have ironclad fields, toothed armatures, carbon brushholders, and slow speed. The details of construction are excellent.

The exhibit included also a 7½ horse-power Churchward automatic self-starting, single-phase motor, and an "equalizer" illustrating the equalizer system that was described in The Electrical Engineer of May 13. Supplementary to all this was a full line of patented carbon brushholders used on the above machines, from the little 4 ampere type up to and including the 2,000 ampere; also rheostats, starting boxes, etc. It was a rounded, complete and very interesting exhibit, and the quality of all the apparatus was such as to reflect great credit on the company.

THE McEWEN MFG. CO.

The operative exhibit of the J. H. McEwen Manufacturing Company, installed at the Electrical Exposition, consisting of a 40 kilowatt Thompson-Ryan multipolar generator, direct-connected to a 10 x 10 McEwen engine, received its due share of attention from the engineering profession and others who visited the show.

Its compactness, pleasing outline and smooth running drew many highly complimentary remarks from the thousands of visitors, and in order to satisfy those who were interested from a practical standpoint, a water rheostat was provided so that any desired load, up to 50 per cent. beyond the rated capacity of the dynamo, could be thrown on and off at will. The normal capacity of the dynamo was 320 amperes, at 125 volts, and the test of throwing on and off 450 to 475 amperes instantly with absolutely no sparking and without racing of the engine was a great surprise to all who witnessed the tests.

MESSRS. JOHN G. KLUMPP & SON, wood turners, of 13 Baxter street, New York, distributed an interesting circular in the gallery of the exhibition, calling attention to the goods they manufacture. They are headquarters for wooden push buttons, and a general line of turned wood work for electrical purposes, as displayed in their showcase.

THE BEAUTIFUL EXHIBIT OF THE SAFETY INSULATED WIRE CO.

WE illustrate herewith the magnificent exhibit made at the National Electrical Exposition by the Safety Insulated Wire and Cable Company, under the direction of Mr. Richards, assisted by Mr. Requa, Jr., and Mr. Eckert. The wires and cables used by the management in the equipment of the show were of Safety make.

The display was eminently common-sense and thoroughly forcible from the advertising standpoint, alike attractive to the electrical expert and the unelectrical layman. In passing the exhibit of the Safety Company, when one was just in front there flashed out a sentence in red and black letters on a white ground, the whole frame in quarter oak and standing on an oaken easel. A moment before, the picture was a blank. Before one had finished there was another little picture on the side wall which told a story and disappeared. Then the eye caught a picture which a moment before had been invisible, showing two of the cruisers of our Navy, equipped, as the legend underneath informed the visitor, with "Safety" wire. In front of the entire exhibit, acting at once as a railing and as a sample board, was displayed very handsomely a full line of samples of wire and cable; pieces a foot long were handsomely attached to an oaken slab and then a cross section of each cable was made and deftly inlaid in the oak so that each sample was fully displayed in its outer and inner character. This in itself was interesting, but when to this fact was added another, that many of these were numbered and were referred to in the electric picture signs in front, the interest was doubled.

EXHIBIT OF THE SAFETY INSULATED WIRE AND CABLE CO.

The manner in which the signs flashed in and out was very clever, and it is safe to say that no one passed by who did not stop and spell out slowly, with the motor-driven mechanism, the signs that spoke so bravely and brilliantly of the company's work and success.

EXPOSITION NOTES.

THE S. S. WHITE DENTAL MANUFACTURING COMPANY, of New York, displayed a varied line of their dental outfits operated by Lundell motors.

THE AMERICAN CARBON COMPANY, of Noblesville, Ind., had their line of carbons artistically arranged and displayed in a neat booth on the main floor. Descriptive circulars, which they distributed, dwelt upon the merits of the goods they manufacture.

THE PECKHAM MOTOR TRUCK AND WHEEL COMPANY, of Kingston, N. Y., showed a handsome truck for a four-wheel electric car, but had no one in attendance, evidently believing that a sample of their celebrated goods speaks for itself, in the excellence of its workmanship.

L. S. BEARDSLEY, Naugatuck, Conn., had a unique display of his manufactures in the gallery of the exposition. Mounted on a wooden frame were two wooden cross arms, to which were adjusted his iron brackets, tridents, etc., for attaching telegraph, telephone and trolley wires. Mr. Beardsley's work showed solidity and excellent workmanship.

FAYERWEATHER & LADEW, 30 Spruce street, New York, had an imposing array of leather belting at their booth on the floor of the generating exhibit. Large double and three-ply belts, single and dynamo belts, twist belting, all of pure oak tanned leather, also rawhide lace leather, give the prospective buyer an excellent idea of the line of superior stock this well-known firm have to offer.

THE CROWN WOVEN WIRE BRUSH COMPANY, of Salem, Mass., had an interesting exhibit of their well-known woven wire brushes for dynamo and motor use, in conjunction with the exhibit of H. B. Coho & Co., who are their New York agents. These brushes are becoming more popular every day, as they are made from the finest quality of soft copper, and are extremely easy on commutators.

THE WESTERN TELEPHONE CONSTRUCTION COMPANY, of Chicago, occupied two spacious booths, one on each side of the entrance on the main floor, so that each stream of visitors as it entered saw their apparatus at once. The display was very interesting and comprised telephone switchboards, long-distance telephones, power generators, and desk sets of various styles; also police and fire alarm systems.

THE J. G. BRILL COMPANY, of Philadelphia, were represented at the exposition by Mr. George M. Hackell, and had on exhibition one of their famous 21 F Standard Broadway trucks. Their exhibit was surrounded by a few printed signs, bearing interesting information regarding the success of the Brill truck, one of them stating that more than 14,000 Brill trucks of the different styles have been supplied to American electric railroads.

THE TUCKER ELECTRICAL CONSTRUCTION COMPANY, of New York, were conveniently housed in a snug booth on the main floor of the exhibition building. Their display comprised interior intercommunicating telephone systems, hotel telephone, factory and private line systems, an interesting novelty also in connection with their exhibit being a desk light which can be attached to any pigeon hole in a roll-top desk. Mr. Wm. A. Moore had charge of the exhibit.

THE FOSTER ENGINEERING COMPANY, of Newark, N. J., regulated the steam pressure of the entire generating plant of the exposition with their efficient pressure regulator and reducing valve. This well-known company also supplied the reducing valves used on the engine operating the automatic stoker, coal conveyor and steam blower, connected with the Root boilers. In addition to these, the Foster Company exhibited their new automatic safety stop valve, designed as a

life and property saver in mines, collieries, on shipboard and in boiler rooms of large steam plants.

THE BRIDGEPORT CAR EQUIPMENT COMPANY, of Bridgeport, Conn., had a very interesting electric third rail exhibit. It consisted in a model of a top rail depressed into contact with a live rail underneath it and which was inclosed in a flexible water-tight steel tube. This system is adapted for both street and steam roads, the former requiring but the removal of a paving block. It is inclosed by protection plates which come together, and form a slot over the depressible rail. The steam road is shown as in a freight yard, overcoming the switching problem. This company claim a large saving in the use of their system.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MAY 19, 1896.

Alarms and Signals:—

BLOCK SIGNAL SYSTEM. A. L. Creelman, Chicago, Ill., 560,193. Filed Dec. 21, 1894.
Consists in operating signals by electromagnetic devices actuated by the current from a main power wire, the action of said devices being controlled by a local circuit containing suitable circuit controllers adapted to be operated by the passing train.

CIRCUIT FOR LATENT SIGNAL TRANSMITTER. F. B. Herzog, New York, 560,212. Filed Feb. 14, 1895.
A normally open circuit signal transmitting mechanism at one station; a circuit closer closing said circuit by the act of preparing said transmitter to transmit its signal, and means, on another circuit, for controlling the operation of said signal transmitter.

TRAIN SIGNAL. W. Biddle, Brooklyn, N. Y., 560,293. Filed March 22, 1894.
Comprises a rolling signal upon an armature lever, two electromagnets for giving motion to the armature lever and to the signal, a circuit closer operated by the armature lever, and electric circuit connections to the central station for indicating the movements of the respective signals automatically.

ELECTRICAL ANNUNCIATOR. G. J. King, Oakland, Cal., 560,358. Filed Nov. 21, 1895.
For hotel use.

DEVICE FOR RAILWAY SIGNALING OR OTHER PURPOSES. M. B. Leonard, Richmond, Va., 650,359. Filed Feb. 5, 1895.
Circuit closer is operated by wheel of passing car.

ELECTRICAL APPARATUS AND SYSTEM. M. B. Leonard, Richmond, Va., 560,360. Filed Feb. 19, 1895.
A block signal system.

ELECTRIC BLOCK SIGNAL AND TRAIN LIGHTING SYSTEM. J. C. West, Atlanta, Ga., 560,451. Filed Dec. 23, 1893.
Consists in mechanism for automatically cutting off the steam of two oppositely moving locomotives and for applying the airbrakes thereof when said locomotives enter the same block.

ELECTRIC BELL. F. and H. F. Keil, New York, 560,506. Filed Dec. 16, 1895.
The combination of the armature with the angular pivoted spring, having the tongue and loop separated at their ends and the bifurcated stud receiving said tongue and loop.

ELECTRIC SIGNALING APPARATUS AND SYSTEM. M. B. Leonard, Richmond, Va., 560,619. Filed Nov. 10, 1894.
Block signal system.

Storage Batteries:—

CONNECTION OF STORAGE BATTERIES. R. McA. Lloyd, New York, 560,272. Filed Nov. 16, 1895.
A secondary battery element having a projection and engaging the mercury, a copper connector secured to the projection and engaging the mercury and provided with a band of enamel between the projection and mercury contact.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE. R. Schorch, Darmstadt, Germany, 560,328. Filed Dec. 14, 1893.
Embodies an open coil armature.

ELECTRIC MOTOR FAN. J. D. Brinser, Lancaster, Pa., 560,569. Filed July 12, 1894.
Details relating to a ceiling fan.

ALTERNATING ELECTRIC MOTOR. R. Lundell, Brooklyn, N. Y., 560,591. Filed Feb. 18, 1895.
An alternating electric motor having field magnet coils and a short-circuited armature, with additional armature coils having circuit connection with a source of current supply adapted to generate currents of low voltage, the field magnet coil being connected directly to the current mains.

Electro-Metallurgy:—

MAGNETIC SEPARATOR. F. J. Barnard, Seattle, Wash., 560,184. Filed Sept. 10, 1895.
Consists of a series of magnets or a magnetized plate located above a non-magnetic base or conveyor plate, which is reciprocated by suitable means over a sluice.

ELECTRICAL FURNACE. E. G. Acheson, Monongahela City, Pa., 560,291. Filed June 25, 1894.
For the production of silicide of carbon.

MANUFACTURE OF METALLIC ARTICLES BY ELECTROLYSIS. M. Perreur-Lloyd, Paris, France, 560,533. Filed Sept. 26, 1895.
Consists in applying to the slight roughness on the surface of the cathode a very thin coating of fatty matter.

Lamps and Appurtenances:—

HANGER FOR ELECTRIC ARC LAMPS. T. H. Brady, New Britain, Conn., 560,255. Filed Jan. 4, 1896.
Consists of a pair of dependent hooks with hollow bases, in each of which is seated a spring extending across the mouth of hook, said spring being provided with a hole to fit over point of hook.

HEAD BLOCK FOR ARC LAMPS. A. N. Edeburn, Cleveland, O., 560,262. Filed Aug. 12, 1895.
Details of construction.

ELECTRIC ARC LAMP. E. J. Bagnall, Cleveland, O., 560,387. Filed Dec. 14, 1895.
The combination with the separating and feeding magnet of an alternating current arc lamp and the carbons, of an armature lever connected directly with the carbons, a retarder and a spring forming the sole connection between said armature lever and the retarder.

ELECTRIC ARC LAMP. J. McLaughlin, Chicago, Ill., 560,421. Filed May 15, 1893.
The current from the line is cut out and directed about the arc of the lamp when from any cause a lamp so cut out has become inoperative.

ELECTRIC ARC LAMP. C. L. Coffin, Detroit, Mich., 560,476. Filed March 13, 1894.
The arc is subjected to the influence of a magnet in which the lines of the field of force are substantially parallel with the current producing said arc.

Measurement:—

ELECTRIC MEASURING INSTRUMENT. E. Thomson, Swampscott, Mass., 560,379. Filed March 29, 1895.
The combination of fixed members composed of coils and a movable member also composed of coils, the coils being disposed and wound so as to balance the movable member astatically in the magnetic field.

Miscellaneous:—

ELECTRIC IGNITER FOR GAS LIGHTING. W. F. Rudolph, Philadelphia, Pa., 560,284. Filed Sept. 6, 1895.
Details of construction.

ELECTRICALLY ACTUATED DENTAL PLUGGER. J. W. Gilbert, Philadelphia, Pa., 560,315. Filed Nov. 7, 1895.
The supporting frame consisting of the two parallel tubes serving, respectively, to receive the plugger handle and as a housing for the spring of the armature hammer, and the end pieces with which said tubes are connected.

ELECTRIC IGNITER FOR GAS LIGHTING. W. F. Rudolph, Philadelphia, Pa., 560,370. Filed Nov. 29, 1895.
Details of construction.

PROCESS OF AND APPARATUS FOR BLEACHING VEGETABLE FIBERS. C. Kellner, Vienna, Austria-Hungary, 560,411. Filed Dec. 5, 1891.
Comprises a pair of bleaching tanks, an electrolyzer having its positive cells connected with one of said tanks and its negative cells with the other, a reservoir common to both tanks, a revoluble stirrer contained in the reservoir, and a pump for pumping the liquid flowing into the reservoir from said tanks back to the electrolyzer.

TREATMENT OF SODIUM CHLORID. J. Meyruels, Paris, France, 560,518. Filed July 24, 1893.
Method of manufacturing chlorine, white lead and bicarbonate of soda.

SALES INDICATOR AND ALARM. C. F. Davis, Missoula, Mont., 560,194. Filed March 3, 1895.
The combination of the series of indicators, means for actuating any desired one of said indicators, with an alarm and connections for operating said alarm whenever any one of said indicators has been operated a fixed number of times.

COIN-CONTROLLED ELECTRICAL APPARATUS. J. N. Peirce, Boston, Mass., 560,423. Filed Feb. 19, 1896.
A coin displaces a detent causing release of the current closing arm.

TYPEWRITING MACHINE. G. H. Davis, Washington, D. C., 560,572. Filed Oct. 2, 1894.
An electrically connected supporting frame suitably hinged in front typewriter frame, a hinged keyboard located above the supporting frame, and a series of electrically connected keys carried by the keyboard.

TYPEWRITING MACHINE. G. H. Davis, New York, 560.573. Filed Nov. 15, 1894. Similar to above.

Railways and Appliances:—

ELECTRIC RAILWAY SYSTEM. J. C. Henry, Westfield, N. J., 560,265. Filed Nov. 26, 1895.
A system whereby the advantage of the "three-wire system" may be availed of and at the same time the potential on different parts of the line may be kept at different voltages.

ELECTRIC RAILWAY. N. Leidgen, Milwaukee, Wis., 560,269. Filed March 11, 1895.
Comprises a hanger having curved sides for receiving the ends of the wire sections, said sides terminating in upwardly inclined cam surfaces and weighted eccentrics pivoted to said hanger for clamping the ends of the wires against said curved sides.

METHOD OF ATTACHING RAIL BONDS TO RAILS OF ELECTRIC RAILROADS. D. W. Payne, Elmira, N. Y., 560,366. Filed Aug. 24, 1895.
The bonds are welded directly to the rails.

POWER GEARING FOR ELECTRIC CARS. E. A. Sperry, Cleveland, O., 560,375. Filed June 6, 1894.
A yielding coupling forming part of power driving, and a casing inclosing said yielding coupling, said casing being integral with the journal bearing of the power driving connection.

ELECTRIC BRAKE. W. B. Potter, Schenectady, N. Y., 560,428. Filed Feb. 3, 1896.
Reverses the relation of armature and field so that they act as generators.

ELECTRIC RAILWAY SYSTEM. G. Westinghouse, Jr., Pittsburg, Pa., 560,452. Filed July 27, 1895.
A circuit closing switch for electric railways, an armature and contact plates and loosely mounted support therefor, provided with downwardly projecting pins or lugs, and a spring on which said pins or lugs rest.

RAIL BOND FOR ELECTRIC RAILWAYS. H. W. Wyman and F. H. Daniels, Worcester, Mass., 560,455. Filed June 26, 1895.
A rail bond having the terminals or ends made integral with the body of the bond and of much larger diameter.

ELECTRIC RAILWAY SWITCH AND BOX THEREFOR. W. Chapman, Washington, D. C., 560,471. Filed July 29, 1895.
A bottom comprising a horizontal base plate, a peripheral flange projecting above said base plate and two concentric flanges below said base plate joined at their lower edges to form a trough or channel.

CURRENT COLLECTING DEVICE FOR ELECTRIC RAILWAYS. W. Chapman and P. W. Davies, Washington, D. C., 560,472. Filed July 29, 1895.
The combination with a car truck and jointed collecting bars, of a supplemental truck for guiding said collecting bars.

ELECTRIC RAILWAY. W. Chapman, Washington, D. C., 560,473. Filed Aug. 1, 1895.
A contact bar, supported, consisting of a plurality of conducting

lengths or sections insulated from each other, with means for cutting either or both of the end sections into and out of circuit.

ELECTRIC RAILWAY. R. Lundell, Brooklyn, N. Y., 560,513. Filed Dec. 6, 1895.

Comprises a current feeder or main, two rows of sectional trolley conductors, permanently interconnected electromagnetic switching devices in combination with a return conductor or rail located between said rows of sectional trolley conductors.

ELECTRIC RAILWAY SYSTEM. D. MacL. Therrell, Charleston, S. C., 560,551. Filed Jan. 9, 1896.

A magnetized shoe is suspended from the car, a ball-bearing device upon the shoe carrying balls of non-magnetic material of good electrical conductivity.

Switches, Cut-Outs etc:—

ELECTROMAGNETIC DASH POT. J. D. Ihlder, Yonkers, N. Y., 560,216. Filed Feb. 8, 1895.

Adapted to be used in connection with electric elevators.

ELECTRIC AUTOMATIC STOP FOR ELEVATORS. J. D. Ihlder, Yonkers, N. Y., 560,217. Filed July 27, 1895.

The combination with an electric motor and a short circuit therefor, of a switch controlling said circuit, and an automatic stop device controlling said switch.

SHUNT CIRCUIT WATER RHEOSTAT. J. Buchel, New Orleans, La., 560,340. Filed Dec. 7, 1894.

Comprises a receptacle containing a liquid, the main circuit plates therein, the shunt circuit plates also immersed in the liquid, the relative positions of the two sets of plates being adjusted.

CIRCUIT BREAKER. W. B. Potter, Schenectady, N. Y., 560,427. Filed Jan. 18, 1896.

Adapted for use on drawbridges.

SAFETY DEVICE FOR ELECTRIC MOTORS. J. D. Ihlder, New York, 560,503. Filed Sept. 12, 1892.

Comprises a duplex shunt circuit of relatively high resistance, including two parts of a magnet-coil, and a safety device arranged in said duplex shunt circuit.

ELECTRIC RHEOSTAT OR HEATER. H. W. Leonard, East Orange, N. J., 560,588. Filed March 20, 1896.

A ribbon-like conductor attached to a large mass of material, having a high specific capacity for heat and insulated therefrom by a minimum thickness of insulating material.

Telegraphs:—

POLAR RELAY. T. B. Dixon, Henderson, Ky., 560,313. Filed March 27, 1896.

Means for preventing polar instruments from being influenced by false currents in the line.

Telephones:—

SWITCHBOARD. D. M. Munro, Gaithersburg, Md., 560,275. Filed Feb. 26, 1896.

Connections between any number of subscribers may be made by sliding out or in a single switch plug.

TELEPHONE RECEIVER. S. D. Field, Stockbridge, Mass., 560,403. Filed Aug. 24, 1895.

In combination with the diaphragm, permanent magnet, and polepiece of soft iron, two equal, reversely acting helices, serially connected in a circuit, one of said helices being nearer the polar extremity of the core than the other.

TELEPHONE SIGNAL AND SIGNALING CIRCUIT. A. de Khotinsky, Boston, Mass., 560,617. Filed March 13, 1896.

Employs the same battery for call signals, for conversation and the operation of disconnecting signals.

MISCELLANEOUS.

THE GREAT STORM IN ST. LOUIS.

THE city of St. Louis was visited last week by a terrific tornado, which devastated also the adjoining town of East St. Louis and the surrounding country. Hundreds of lives were lost, many people were injured, and the destruction of property is said to have reached $50,000,000. All the trolley car systems were terribly crippled by the breakage of their lines, and the damage to cars and power plants.

The Missouri Electric Light and Power Company escaped damage to the power house, but in many places the wires and a great many of its poles went down. The estimate of poles down reaches 500. The company has sufficient reserve supplies on hand to repair its loss, and 200 linemen at work, but fully three or four weeks will elapse before all connections are made.

With the Edison Company the poles and wires in about 200 blocks from the levee to Grant avenue and from Rutgers to Clark avenue were torn down, and every arc lamp was smashed. The power house was a wreck, although the machinery was not greatly injured.

Expert electricians and linemen and even laborers were imported from neighboring cities in large numbers to reconstruct the broken telephone, telegraph, and electric light lines. Car loads of telegraph poles, wiring, and lamps and various electrical apparatus are arriving, and with the stocks constantly carried by the various companies furnish material for thousands of workmen. The Bell Telephone Company's wires along the track of the storm are a total loss. The company carries a heavy supply, and was enabled to start 500 men at work. A conservative estimate of the company's loss is $75,000.

The Postal Telegraph Company lost only about $4,000, their damage being of such a nature that it is easily repaired.

The Western Union had 300 men in East St. Louis last week untangling wreckage preparatory to repairing wires. The extent of the loss the officials cannot yet estimate.

The Wagner Electric Manufacturing Company telegraph us that they escaped entirely the effect of the storm; that no delay will be experienced at their factory, and that all orders will be filled as per contract. They are naturally very busy at this time, but have splendid facilities.

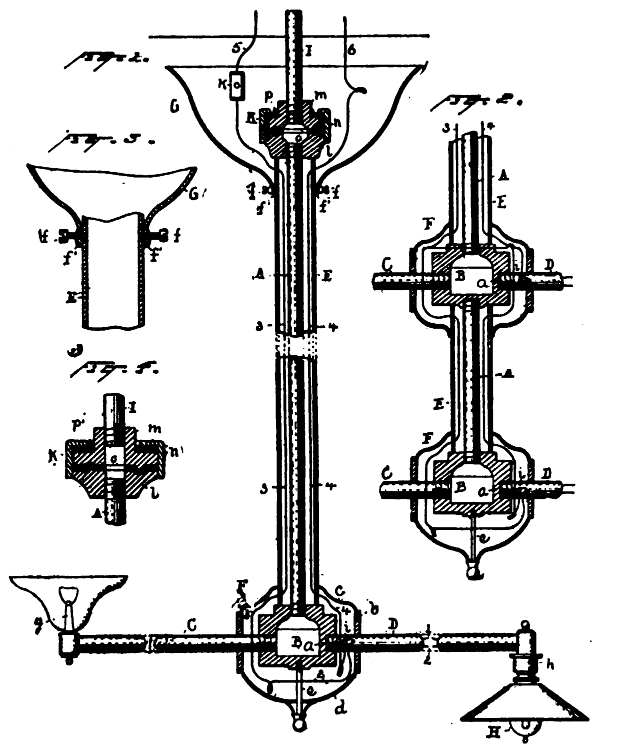
Mr. H. L. Parker, the president of the Emerson Electric Manufacturing Company, writes us that they escaped entirely, their factory not being in the path of the storm. All the homes of the officials were untouched, except that of Vice-President Steinwender. His house was utterly demolished, but his family, we are glad to say, had the great good fortune to escape without any injury.

PATENT NOTES.

THE STIERINGER COMBINATION FIXTURE PATENT.

MR. LUTHER STIERINGER, on May 26, 1896, obtained another reissue patent, No. 11,544, for combined gas and electric light fixture, which, it is claimed, covers the fixtures known as "combination fixtures" employed for illuminating by gas or electricity. The underlying idea of this fixture is to employ separate arms for the gas and for the electric light with a system of conductors directly connected together, so that an integral fixture of unitary design is produced, and in which all of the electrical conductors are concealed, the result being that the fixture practically resembles a gas fixture, the electrical additions in no wise disturbing the harmony of the design.

The claims of this reissue patent are seven in number. The



DRAWINGS OF STIERINGER'S COMBINED GAS AND ELECTRIC LIGHT FIXTURE PATENT.

first four relate to the construction of the fixture to accomplish the purposes mentioned. The fifth and sixth claims include the combination with such a fixture of an insulating joint so as to protect the fixture from the metallic gas pipe outlet. The seventh claim is on a particular form of insulating joint.

It will be recalled that the reissue patent granted to Mr. Stieringer on the simple electric fixture was recently sustained by Judge Coxe. The combination reissue has been taken out on the same lines as the other reissue, by Messrs. Dyer & Driscoll, the attorneys for Stieringer. This reissue patent is of very great importance to the fixture trade, covering, as it does, the combined use of gas and electricity in the same fixture, such fixtures constituting a majority of the entire output.

PROFESSOR A. G. BELL is reported to have been working on an automatic telephone exchange system, which shall enable people to call up each other without the intervention of "central." No details have been given out, and Professor Bell is now away at his summer residence at Cape Breton.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

THE ROOT BOILER.

The Abendroth & Root Manufacturing Company, 28 Cliff street, New York City, are distributing some handsomely illustrated leaflets describing the Root boiler, and showing illustrations of a large number of prominent buildings where they are installed. This boiler having been on the market since 1867, is too well known to require special description. Among its claims may be mentioned the fact that it can have any of its details replaced in less than two hours without the services of a practical boilermaker, as all of its parts are made on the interchangeable system. It also admits its circulating water directly to its lower tubes, thus protecting them from the intense heat of the fire. The boiler can be put into any building through an opening 40 inches square, avoiding tearing up sidewalks and streets, and can have its capacity increased at any time at a minimum of cost by placing additional packages of tubes on top or alongside of those already in the boiler. Among the list of users of the Root boilers may be found many of the prominent electric light and electric railway companies.

AN ELECTRIC LIGHT FOR BICYCLES.

It seems that we are at last to have a bicycle lamp that is worthy the name. The Ohio Electric Works, 13 South Water street, Cleveland, have begun the manufacture of an electric lamp that is warranted to burn, to give a light and to last. It is also claimed that it will not go out when a policeman happens to be around.

In its general appearance the new lamp does not differ much from the oil lamps, except that it is narrower and the reflector which holds the lamp projects further from the surface. The body of the lamp resembles a small electric cell more than anything else, and that is really what it is. It is attached to the front of the bicycle in the ordinary position.

The power which supplies the light indicates how common and handy electricity has become. The electrolyte is bought in a solid package and is known as a "charge." The construction of the lamp is so simple that any one can recharge it without difficulty.

The light is furnished by a small incandescent lamp backed by a powerful reflector. The annoyances occasioned by grease, oil and gas are done away with. There is no smell and no smoke, and one charge of the battery is said to be sufficient to maintain the light for several hours.

STORAGE BATTERY PLANT TO BE INSTALLED FOR THE HARTFORD ELECTRIC LIGHT CO.

A water power of about 3,000 horse, situated about eleven miles from Hartford, is to be used to drive Westinghouse multiphase alternators, the power to be transformed at the Falls to 10,000 volts and transmitted on a pole line to the Hartford Electric Light Company's station in Hartford, Conn., where it will operate motors, driving shafting, to which will be belted arc lighting machines, and from which point alternating current will be distributed for incandescent lighting.

From the station mentioned the current will be carried to the storage battery station at a pressure of 2,000 volts, where it will be transformed to 240 volts and put through a rotary transformer for charging the battery which will be operated on three-wire system.

The battery will consist of no fewer than 140 10,000 ampere hour chloride accumulators, the largest such plant in the world.

INTELLIGENT "PIONEER" ADVERTISING.

In looking over the pages of the present edition of The Electrical Engineer, we feel sure that our readers will stop at page V. and give a second look at the pretty and unique notice of the Pioneer enclosed arc lamp. The "Pioneer" folks tell us that their long hour lamp has many imitators, and we trust that their line of advertising will awaken slumbering ideas in the minds of others and thus help us in making every page of our paper attractive and interesting.

ELECTRIC APPLIANCE CO.'S BLANKS.

The Electric Appliance Company have brought out two more very clever and original advertising schemes in the shape of a pad or tablet of blank forms, on which can be recorded thirty minute readings of the number of amperes as shown by the station ammeter. This gives a permanent record of the station load at thirty minute intervals during the entire twenty-four hours.

Their other scheme is a complete set of architects' specifications for electric wiring which can be used as a form for making comtracts for electric wiring. These specifications have been carefully drawn by a well-known consulting electrical engineer and will be found valuable guides in all electric light work. The Electric Appliance Company are prepared to furnish either or both of these free on application.

CRAFTS & ISSERTEL.

This new firm of electrical engineers, contractors, etc., has started in actively and has made a very encouraging début. It is composed of Mr. Henry G. Issertel, E. E., and Mr. S. D. Crafts, and has an abundance of experience and ability. The firm, as one of its chief interests, represents the Walker Manufacturing Company, and has the care of the New York agency. It is very much elated over the recent capture of the order for the Brooklyn Bridge. The firm has its headquarters in the Postal Building.

LARGE PLANS OF THE NEW WALKER CO.

A special dispatch from Albany of May 26 says: A new electrical manufacturing combination called the Walker Company has been formed to fight the General Electric and Westinghouse companies. New York, Philadelphia, Boston and Cleveland capitalists are interested. Among them are ex-Governor Flower, Anthony N. Brady, J. W. Hinckley, Belmont Dallas Sanders, William Rotch, Parker C. Chandler, Frank Billings and Jacob B. Perkins. They have factories in several places, the largest being in Cleveland, where upwards of 2,000 men are employed.

The company has just secured the contract for furnishing the electric plant for the New York and Brooklyn Bridge, also for two railroads in Chicago and for some of the equipment for the elevated railway there, and for roads in Kansas City and Detroit, and for the great store of Jordan & Marsh in Boston. J. W. Hinckley, of Poughkeepsie, who organized the new company, says that no combination will be made with the General Electric and Westinghouse companies. He says the capital of the newly combined companies is only $5,000,000 as against nearly twenty times that amount as represented by the stock and bonds of the General Electric and Westinghouse companies. Mr. Hinckley claims that in consequence the new combination will be able to undersell the trust on all kinds of machinery and still make handsome profits.

WESTERN TELEPHONE CONSTRUCTION CO.

The Western Telephone Construction Company, of Chicago, report a large increase in their orders. Recent contracts are: DuQuoin, Ill., 100 telephones; Ashland, Ky., 150; Bellaire, O., 75; Metropolis, Ill., 60; Oberlin, O., 150; Wauseon, O., 100; Barnesville, O., 200 exchange equipment; Rochester, N. Y., 50 telephone equipments; Ticonderoga, N. Y., 150 exchange outfits. They have also just shipped a 400 telephone exchange equipment to the Mutual Telephone Company, of Petersburg, Va., to replace other apparatus.

I-T-E.

It seems almost impossible to realize with what favor the "I-T-E" automatic magnetic circuit breakers, manufactured by the Cutter Electrical and Manufacturing Company, of Philadelphia, have been received by all those interested in matters electrical. Scarcely a prominent engineer but has approved or indorsed their use, and the underwriters of the cities of New York, Chicago, Boston and Philadelphia have also approved them. As is usually the case in all inventions and improvements, the "thing" or feature is some little modification or development which is apparent at first glance, and which, seemingly, should have been thought of before. The letters "I-T-E" in brief represent the salient features of the automatic magnetic circuit breakers, viz., I-T-E means "Inverse Time Element," and represents the basic principle entering into the construction of the device, namely, that a circuit protected by this circuit breaker is opened in less and less time, as the circuit approaches nearer and nearer a short circuit.

The circuit breakers are made for switchboards, railways, light and power, motors, house service and storage batteries, in direct and alternating circuits.

The catalogue will repay careful reading and will be sent to all interested in this important subject, upon application.

Department News Items will be found in advertising pages.

Vol. XXI. JUNE 10, 1896. No. 423.

Electric Transportation.

THE EFFICIENCY OF COMPRESSED AIR FOR STREET CAR MOTORS.

BY ROBERT LUNDELL.

THE object of this paper is to correct the erroneous impressions created by the recent newspaper reports upon compressed air motors, and in particular to remove confusion from the minds of the readers of Mr. Herman Haupt's book, "Compressed Air and Electricity." It is admitted that in order to properly answer the statements and conclusions given in this book it would be necessary to write another book of almost the same volume and to deal with mathematics to a considerable extent. This being out of the question at present, it will be sufficient to deal with the main point, that of efficiency.

Mr. Haupt states (see page 10) that 300 cubic feet of free air will run an eight-ton motor car one mile (or 3,600 cubic feet, twelve miles). With an interval of one minute between cars this would mean 3,600 cubic feet per minute. Without criticising the figures, it may be advisable to point out that these remarkably small figures were obtained at Rome, N.Y., under the very best conditions of track, etc. To obtain the same results in speed, etc., under street railway conditions, it is safe to say the horse power must be at least doubled. However, this does not matter at present, as this paper will deal only with the ratio of output to input. We will thus take Mr. Haupt's figures of 3,600 cubic feet of air to be compressed per minute, also the figures in regard to the working pressure, 125 lbs. per square inch, and reservoir pressure, 2,000 lbs. per square inch. We will also assume that no air is lost through leakage, and that the air is reheated to such an extent that it comes out of the motor cylinder at almost the same temperature as it was when it first entered the compressors. This condition, of course, is not obtainable in practice.

Let us now suppose that an air compressor is driving air into a reservoir in which the pressure is 125 lbs., and that an air motor is directly supplied from the same. In order to obtain the highest possible efficiency we may also suppose that the heat generated in the compressor in some ingenious way is utilized in reheating the air as it expands in the motor cylinder. Under these conditions we need only consider the mechanical efficiencies of the compressor and motor.

We may put efficiency of compressor............	80	per cent.
We may put efficiency of motor................	75	" "
Thus, total plant efficiency..................	60	" "

Now, if we could practically carry on a car a reservoir large enough to contain air at slightly more than 125 lbs. at the commencement of the run and slightly less than 125 lbs. at the finish of the run, we might then hope for an efficiency somewhat approximating 60 per cent. But to carry such a reservoir is impracticable, and it has been necessary to compress the air to 2,000 lbs. instead of 125 lbs. per square inch. To compress 3,600 cubic feet per minute to 2,000 lbs. per square inch, a much greater amount of work is required than to compress the same volume to 125 lbs. As the motor cannot utilize any greater pressure than 125 lbs., the additional work done in the station by the air compressors is lost at the pressure-reducing valve. If an air motor could be constructed that could utilize the expansive energy of air from 2,000 lbs. down to 125 lbs. this work would of course not be lost. But as such a motor would be still more impracticable than to carry a reservoir on the car large enough to contain air at only 125 lbs., it now remains to be seen how much work is lost, or, better, how high an efficiency can be expected from compressing air to 2,000 lbs. and utilizing the same at only 125 lbs.

It will be necessary, first, to calculate what horse-power is required to compress 3,600 cubic feet of air per minute into a reservoir where the pressure is 125 lbs., and, second, what horse-power is required to compress 3,600 cubic feet of air into a reservoir where the pressure is 2,000 lbs. We will use the following notations:

L = Work in foot-pounds.
p_1 = 1 atmosphere (2,116 pounds per square foot).
p_2 = Pressure in reservoir in atmospheres.
v_1 = Volume of the air at pressure p_1 (3,600 cubic feet in this case).
v_2 = Volume of the air at pressure p_2.
n = 1.4 (constant).

1. If the air is compressed at constant temperature (that is, if all heat generated by the compression is instantly carried off) the work consumed is calculated according to the formula:

$$(1)\qquad L = v_1\, p_1 \int_{v_2}^{v_1} \frac{dv}{v} = v_1\, p_1 \times \log_e \frac{v_1}{v_2}$$

which gives $L = 3,600 \times 2,116 \times \log_e 8.5$ for a compression to 125 lbs. or 8.5 atmospheres; or the H. P. $= \frac{L}{33,000} = 495$.

If the air is compressed to 2,000 lbs., or 136 atmospheres, we find:

$L = 3,600 \times 2,116 \times \log_e 136$, and the H.-P. $= \frac{L}{33,000} = 1,133$.

We see from this that the work consumed in compression varies as the hyperbolic logarithm of $\frac{v_1}{v_2}$ and that the efficiency under these (the most favorable conditions) is as $\frac{495}{1,133}$ or 44 per cent.

2. If no heat is allowed to escape during the compression, the total work consumed is calculated from formula:

$$(2)\qquad L = \frac{n\, v_1\, p_1}{n-1} \left\{ \left(\frac{p_2}{p_1}\right)^{\frac{n-1}{n}} - 1 \right\}$$

For 125 lbs. or 8.5 atmos., $\therefore L = \frac{1.4 \times 3,600 \times 2,116}{.4} \left\{ 8.5^{\frac{2}{7}} - 1 \right\}$;

and H.-P. $= \frac{L}{33,000} = 678$.

For 2,000 lbs. or 136 atmos., $L = \frac{1.4 \times 3,600 \times 2,116}{.4} \left\{ 136^{\frac{2}{7}} - 1 \right\}$

and H.-P. = 2,480.

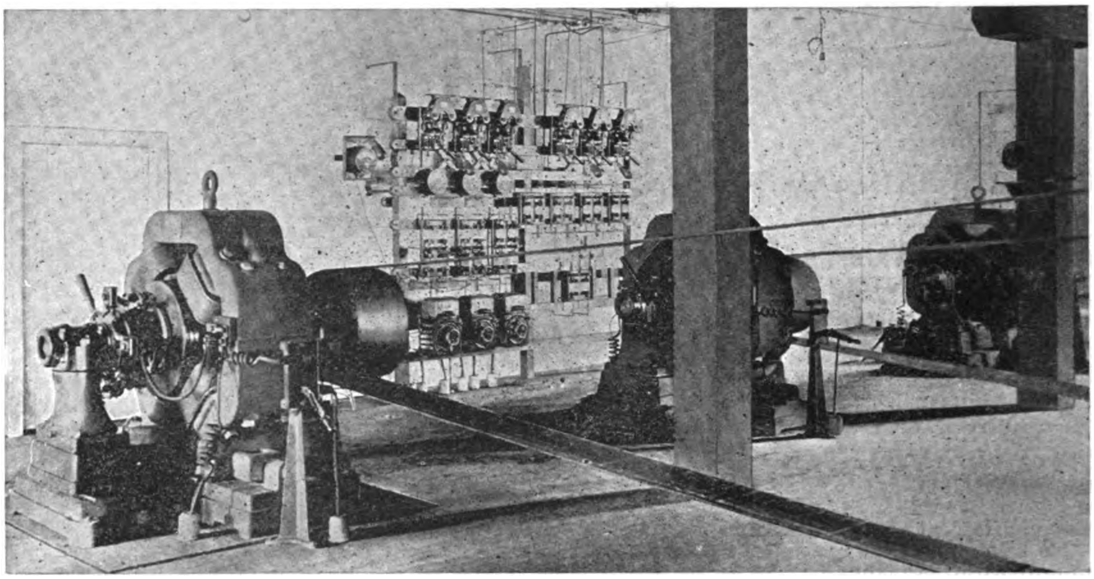
We see from this that the work consumed has increased enormously and in a different ratio from the above case. The efficiency could only be $\frac{678}{2,480}$ or 27 per cent., as against 44 per cent. in the former case. It is fair to assume that if proper means are employed to prevent the temperature from rising too high in the air compressors that an efficiency of about 40 per cent. can be obtained.

Having now determined the efficiency of storing air at a pressure of 2,000 lbs., with a working pressure of 125 lbs., we are ready to estimate the total plant efficiency, leaving out all losses from leakage. In the first part of this paper the mechanical efficiency of an air compressor compressing air to 125 lbs. was supposed to be 80 per cent. But a compressor working under 2,000 lbs. would need more packing and the friction losses would in consequence be considerable. It is liberal to put the mechanical efficiency of the air compressor or compressors at 70 per cent.

Efficiency of storage as before..................	40	per cent.
Efficiency of motor as before...................	75	" "

Or total plant efficiency .70 ÷ .40 × .75 = 21 per cent. under the the most favorable conditions.

It will be understood from the above that reheating of the air at the pressure-reducing value is absolutely necessary. If not reheated the temperature of the air as it enters the engine and finally escapes from same would be so low that its volume would be considerably smaller than when it enters into the compressors at the station. The formation of ice on the working parts would also materially reduce the efficiency.



Power Installation, Youghiogheny River Coal Company.

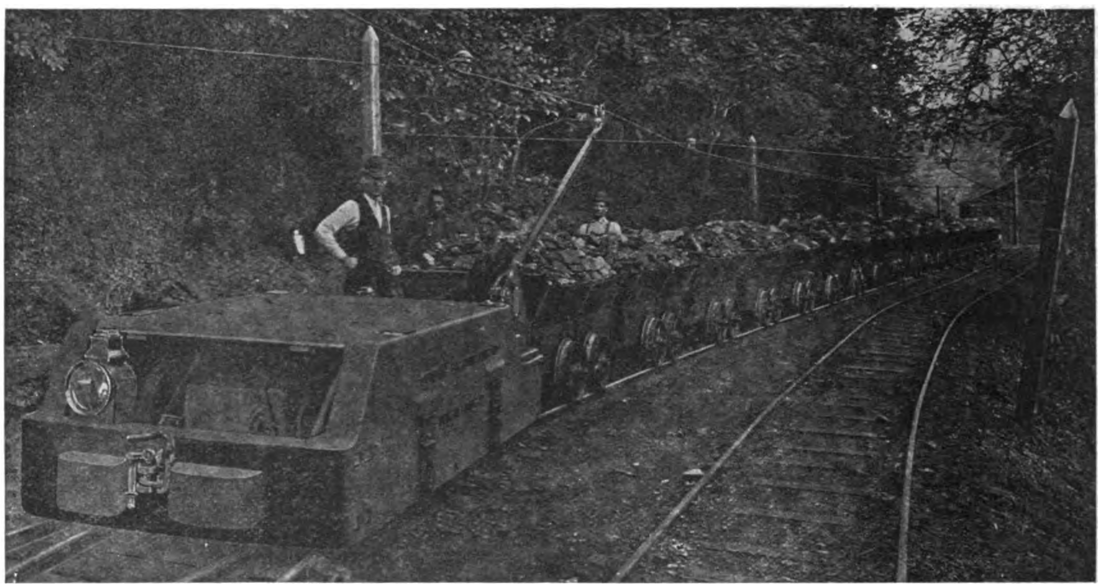
ELECTRICITY IN THE YOUGHIOGHENY RIVER COAL CO.'S MINES.

AN interesting electrically operated coal property in the Pennsylvania field is that of the Youghiogheny River Coal Company, at Scott Haven, Pa. The mines in which the different machines driven by electric power are installed, are scattered over a large extent of territory.

The power house is located on the east side of the Youghiogheny River contiguous to the line of the B. & O. Railroad. It was formerly a bonded warehouse and contains, not only the machinery, but also the stores and offices.

The engine room is 74 feet long by 54 feet wide, and is separated by a brick wall from the power house. The engine installation consists of three automatic engines, each 15 x 16 inches, with seventy-two-inch fly wheels, running at 240 revolutions. Each engine is belted to a four-pole 650 revolution, 100 kilowatt General Electric generator, wound for 500 volts, and overcompounded for 10 per cent. loss in the line. The engines and dynamos are erected on brick foundations, and current from the generators is carried under the floor to the switchboard by heavily insulated cables hung on porcelain insulators.

The switchboard is of the skeleton type, divided into two parts, one for the generators and one for the feeders, on a plan similar to that used in electric railway stations. The generator board carries three automatic circuit breakers, three circular dial Weston ammeters, three main double-pole, double-throw switches and three field rheostats. The voltmeter is carried on a bracket on the side. Two sets of circuits are run, one of which is grounded, for haulage work, and the other insulated, for the fans, coal cutters, etc. Any machine may be run on either the insulated or the grounded circuit. The feeder switchboard carries an automatic circuit breaker for each of the haulage circuits, a double-pole switch for each pump circuit, fan circuit and the coal cutter circuit, and a double-pole switch for throwing the metallic and grounded bus bars into multiple. Lightning arresters protecting the generators are placed behind the switchboard. From the power house the circuits for No. 1 mine are run on poles to the mine mouth. This mine is about 900 feet from the power house and the circuit is used to drive fans, pumps, locomotives



Electric Haulage of Coal, Youghiogheny River Coal Company.

and coal cutters. The fan is a Capell exhaust fan 8 x 3½ feet in diameter, running at 280 revolutions per minute, driven by a belted 25 horse-power multipolar motor, running at 650 revolutions.

All the coal cutting is being done in No. 1 mine by five Jeffrey chain coal undercutters, operated a mile and three-quarters from the power house. The circuit for the coal cutters is insulated, the other circuits all having earth return. This mine is also provided with a Knowles triplex pump, 6½ x 8 in., driven by a 7½ horse-power multipolar motor. The pump, motor and rheostat are mounted on an iron truck and may be run over the track from place to place in the mine.

The electric locomotive operated in this mine has a length of haul a little over a mile and a quarter. The grades vary from 1 per cent. against loads, to 25 per cent. in their favor. The track is laid on thirty-pound rails with a gauge of 43½ inches. The overhead construction is of the regular mining type. The pump and haulage circuits are all grounded for the return.

The fact that the various mines are separated from each other by water introduces a novel feature into the installation and illustrates the flexibility of electric power transmission. For each of the other mines in the Youghiogheny Company's system, current has to be carried under the Youghiogheny River by heavily insulated and armored cables, to a small cable house, forming the center of distribution for the lines running to the mines on the west side of the river.

In No. 4 and in the southwest mines, electricity is applied to pumping purposes only. The pumps are triplex pumps, similar to those in No. 1 mine, and are driven by two multipolar slow-speed motors of 10 horse-power and 7½ horse-power, respectively. These pumps are about 8,000 feet away from the power house.

In the Pacific mine the haulage is effected by a locomotive having a drawbar pull of 2,500 lbs., with a length of haul of about 5,000 feet underground and 800 feet in the open. This mine also contains a pump, similar in size to that in No. 1 mine, driven by a 7½ horse-power motor, located about 16,000 feet from the power house. A 30 horse-power motor fan is erected about 1,000 feet beyond the pump. The installation of the electrical apparatus in No. 5 mine is not yet completed.

In the new steel tipple of No. 1 mine a 7½ horse-power motor drives a revolving screen and runs an emery wheel for sharpening bits, etc. The installation of electricity in this mine has proved of considerable benefit from every point of view. A fair idea can be obtained of the economical value of electric haulage from the statement that the two locomotives have displaced eighteen mules and their drivers, and the four pumps, which take only a small share of the attention of three separate men, are doing the work with which ten men, four mules, two steam boilers, and two steam pumps formerly found it difficult to cope.

THIRD RAIL TESTS ON THE NANTASKET BEACH ROAD.

ELECTRIC traction by means of a third rail was thoroughly tested by officials of the New Haven road at the Nantasket power station recently. It is pretty definitely settled that the overhead system now in use on the Nantasket branch will be abandoned in favor of the third rail, and contracts have already been made for the equipment of part of the line.

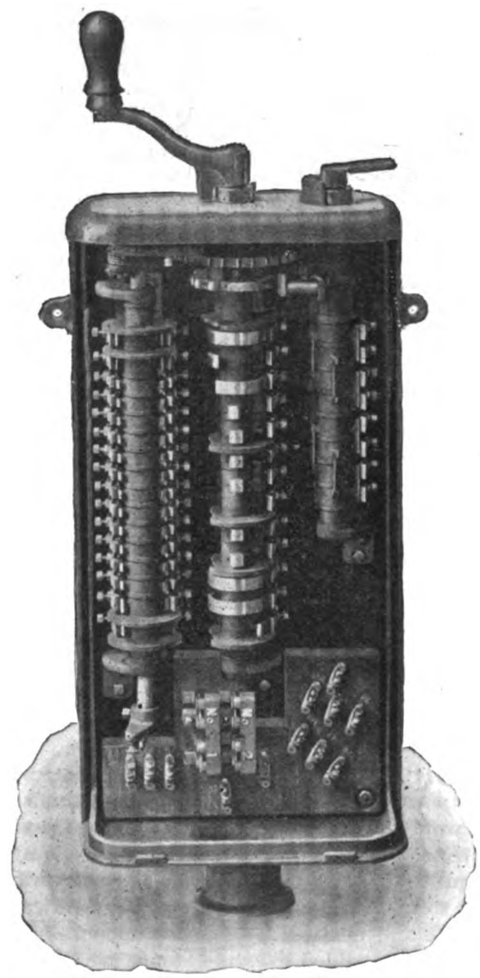
The trial was thoroughly satisfactory, and those who were present expressed themselves as being confident that the system will be successful. It was effectually demonstrated that great speed and efficiency could be obtained, fully as great, in fact, if not greater than, with the overhead system. The rail is alive for its whole length, and will be equipped with some protection similar to that in use on the Intramural Railway at Chicago. Each rail is mounted on three blocks of wood, which keep it from touching the ground. It is broad and flat, and has a flange at each edge which reaches down over the blocks of wood, giving a sort of inverted V shape to the whole, as seen end on. The application from the car is not made by a wheel, as in the overhead system, but by a shoe, which slides along the top of the rail. The blocks on which the rail rests are about six inches square and four and one-half inches high, the height of the whole structure being six inches from the trestle. The rails are coupled with copper bonds, which take the place of fish-plates on the ordinary rail, and are bolted to the flanges where they project over the blocks of wood. The whole structure projects about one and one-half inches above the rails.

THE WALKER "TYPE E" STREET CAR CONTROLLER.

THERE is probably no other class of apparatus that has to operate with as little attention and under as much abuse as that employed in the operation of street cars. It is very necessary that this fact be borne prominently in mind in designing machinery for such service.

The controller is one of the most important elements of a railway outfit. Controllers that two years ago were operated satisfactorily under the general run of service, would now prove inadequate on account of the increased requirements. With these facts in mind the Walker Company has, during several months past, built and experimented with a number of different forms of controllers with a view to determining the most practical and simplest form to place upon the market.

As no means is known of breaking a circuit of high self-induction without forming an arc, efforts have been directed to devising methods of breaking which will be as little destructive as possible to the terminals and other apparatus. On account of the induction effect a short break is more injurious to the insulation than a slow break is, but with the latter a long arc will be produced. After a large number of practical tests it was found that the principle of drawing a long arc with a relatively slow break gave the most satisfactory results. Consequently this principle has been adopted in the design of the new controller recently brought out by the Walker Company. In this controller the circuit is broken by a special switch placed in the controller, in which the action is relatively slow and the circuit is broken at twenty-eight points, thus very easily rendering the most severe arc that can be formed in practice entirely harmless both as to spreading to other contacts and as to its effect on burning the breaking contacts themselves.



WALKER STREET CAR CONTROLLER.

Another novel feature has been adopted, which consists in entirely separating the operation of breaking the circuit from the controlling cylinder itself. The controller consists of two switches, each having its own separate function to perform. The controlling cylinder proper is used simply to make the

different combinations required to obtain the proper regulation of the speed of the car. The second switch is also of a cylindrical form, but is used for no other purpose than the complete breaking of the circuit whenever such is required. By reference to the accompanying engraving, it will be seen that the breaking switch, which is shown at the left, has its circuit so arranged that the main current passes first through this switch before going to the controlling cylinder. In the four lines of contacts shown, the first and third constitute the cylindrical portion of the switch and are in metallic connection each with the one horizontally opposite to it. The second and fourth rows represent the fingers bearing upon the cylinder contacts. It will be seen by following out these connections that when the switch is closed the upper contacts shown in outline are short circuited, the current simply passing from top to bottom and then direct to the controlling cylinder. As this switch is opened the fingers leave the lower contacts, shown solid, first throwing the main current through the upper breaking contacts in the series, so that when the fingers leave the cylinder contacts the arc is broken up into as many parts as there are breaking fingers.

The mechanism of the breaking switch is so arranged that with a movement of the controlling handle one-quarter of an inch backward, the circuit is completely opened leaving the controlling cylinder itself entirely dead. The circuit cannot be again closed until the controlling handle has been brought back to the off position. After the circuit has been once opened by this slight backward movement of the handle, the controlling cylinder can be moved backward and forward into any position without producing any effect, and it is absolutely necessary to go back to the off position before the switch can be again closed. This feature of the controller makes it impossible to drop back from one notch to another in such a way as to put in or take out resistance in the circuit. Another point of advantage is the quickness with which the current is thus cut off.

A very simple and effective interlocking device has been adopted in this controller in which the pawl that indicates the various running positions of the controlling cylinder acts at the same time as a lock between the controlling cylinder and the reversing switch. The internal wiring of the controller is very simple, and, as will be seen, is entirely open, so that it can be easily reached. With this efficient method of breaking the circuit it has been found that separators between the various contacts are unnecessary. In fact the arcing in this controller under the severest conditions of practice is so slight that it is scarcely noticeable.

One of the important features of the controller is the ease with which all the parts can be reached when necessary. The breaking cylinder is so designed that when from continued use the contacts have become worn, the cylinder can be turned end for end and the opposite edges of contact brought into service, thus practically completely renewing the cylinder itself.

THE HORSELESS CARRIAGE RACE.

Of the twenty-eight horseless carriages which it was announced would participate in a parade on Decoration Day, starting from City Hall Park, New York City, only six put in an appearance up to 12 o'clock, when the start was made. On their way through the city the six carriages attracted considerable notice and elicited favorable comments on the part of spectators. They glided over the stones with great ease. The engineers of the novel vehicles experienced no difficulty in making their way through the crowded thoroughfares.

A race was also a part of the programme. This began at Kingsbridge and ended at the Ardsley Country Club. The route was by way of Yonkers, Hastings and Dobbs Ferry. The judges invited to decide upon the winner were General Nelson A. Miles, Chauncey M. Depew, Frank Thompson, vice-president of the Pennsylvania Railroad, General W. P. Craighill and John Jacob Astor. One or two of the carriages returned to the City Hall by the same route, not all of them being able to hold out. There were no electric competitors.

THE TRUMP MANUFACTURING CO., Springfield, O., are building a waterwheel for the Oswego Street Railway Company, of 642 horse-power, 16 feet head, the largest single wheel that can be built and shipped.

THE ELECTRIC CARRIAGE AND WAGON CO., of New York City, has been formed to make and sell storage battery vehicles. Its capital stock is $300,000. The directors are H. G. Morris, W. W. Gibbs, P. G. Salom, I. L. Rice, P. L. Anderson, R. B. Hartshorne, and W. Halls, Jr.

POWER TRANSMISSION.

MOTOR CONTROL.

BY JAMES BURKE.

THE ELECTRICAL ENGINEER of May 6 contains a criticism by Prof. Anthony of a method of motor control devised by the writer, and explained in The Electrical Engineer of April 15.

Prof. Anthony bases his arguments on the application of this method to conditions in which a constant power is required at variable speed and also to conditions in which a constant torque is required at variable speed, and consequently a variable power. In considering the latter conditions, Prof. Anthony misapplies this method of regulation, for it is clearly stated in the description of the method that the conditions are the delivery of "10 horse-power at any speed between the limits of 100 and 500 revolutions," and Prof. Anthony considers an entirely different problem in which the conditions are the delivery of a variable power, varying from 10 horse-power at 100 revolutions to 50 horse-power at 500 revolutions. By this misapplication it is shown how enormous the machines would become, which fact would in itself indicate that the method was being applied to a problem which it was not intended to solve.

Prof. Anthony compares this method, applied to the problem of constant torque, with a system in which a rotary transformer is used, and finds that the latter requires much less machinery, but if the comparison is made on the basis of the application to the problem stated, namely, constant power, it will be seen that his conclusion becomes reversed, because this method requires two motors of 5 horse-power each, at 100 revolutions, and the rotary transformer method requires one motor of 10 horse-power, at 100 revolutions, and also a rotary transformer consisting of a motor and a generator, each of which has an output greater than 10 horse-power.

The writer does not intend herein to criticise the systems in which rotary transformers are used, for there are many conditions which the rotary transformer systems fulfill better than any other, but the problem under discussion is not one of them.

Prof. Anthony's argument against the application of this method to the problem stated, namely, the delivery of 10 horse-power at any speed between the limits of 100 and 500 revolutions, in which the writer uses two motors, each of 5 horse-power, at 100 revolutions, seems to be stated in the following quotation from his criticism: "By making one machine capable of delivering 10 horse-power at 100 revolutions—a machine that would be less costly than two machines of 5 horse-power each—the regulation of speed could be obtained by varying the strength of its own field, with the same facility as by the method described by Mr. Burke." In other words, Prof. Anthony proposes to use a 10 horse-power, 100 revolution motor, and to increase the speed to 500 revolutions by reducing the strength of field to one-fifth its normal strength and maintain a delivery of 10 horse-power.

The writer believes this to be impracticable, because, although this range of field variation can be accomplished when a motor is doing no work, still, it is not possible with constant voltage on the armature and constant delivery of the normal power, to operate a motor successfully with the field reduced to one-fifth its normal value. This conclusion is the result of tests on several machines wherein it was desired to determine the limits of speed control by field variation. This must not be confused with conditions in which a reduction of voltage on the armature accompanies the reduction of field strength and where a reduction in delivery of power in the machine takes place.

In conclusion, the writer wishes to say that the many different problems which arise in the operation of electric motors from supply circuits are so varied that several systems of operation and control have been devised, each applying to some special problem or class of work. Each of them has its place and must not be misapplied. It will be of interest to note that the particular problem of 10 horse-power, at all speeds has been met with in several instances by the writer; also that the particular problem of 10 horse-power, at all speed from 100 to 500 revolutions is one that has been met with in actual practice. The method pointed out by Prof. Anthony, namely, control by varying the strength of the motor field, although useful in many instances where a small range is required, would be inoperative if applied to the conditions of the problem stated, and is therefore not considered practical in this instance.

New York, May 18, 1896.

MISCELLANEOUS.

A METHOD OF INCREASING THE STRIKING DISTANCE OF A GIVEN E. M. F.

WHILE experimenting with high tension apparatus, to determine the effect of different terminals and different arrangements of circuits on striking distances, I observed the following interesting phenomenon:

A spark gap was arranged as shown in Fig. 1. The spark gap terminals, C D, consisted of 1-inch cylindrical brass rods turned to hemispherical shape on the ends. The glass plate was placed in contact with the two terminals. A sheet of tinfoil about 6 inches by 10 inches was placed on the opposite side of the glass plate from the terminals, and bridging the space

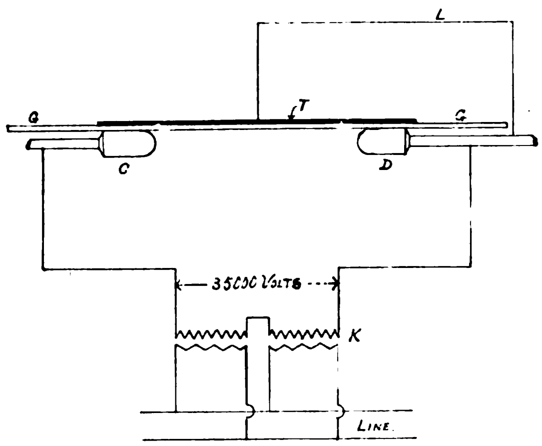


FIG. 1.—C, D, SPARK GAP TERMINALS; G, G, GLASS PLATE; T, METAL FOIL; L, CONNECTION BETWEEN D AND T; K, BANK OF CONVERTERS GIVING VARYING E. M. F.'S UP TO 35,000 VOLTS.

between them. This tinfoil was electrically connected to the terminal D. It was found that with arrangement the striking distance of the e. m. f. used was many times increased above that which could be obtained if the glass plate and tinfoil were removed, or if the connection between the terminal D and the foil was broken.

In the first experiments made, a bank of converters giving a maximum e. m. f. of 35,000 volts at 16,000 alternations per minute was used. The striking distance in air with 1-inch hemispherical terminals was about .7 inch. The striking distance with the glass plate and the tinfoil connected as shown was

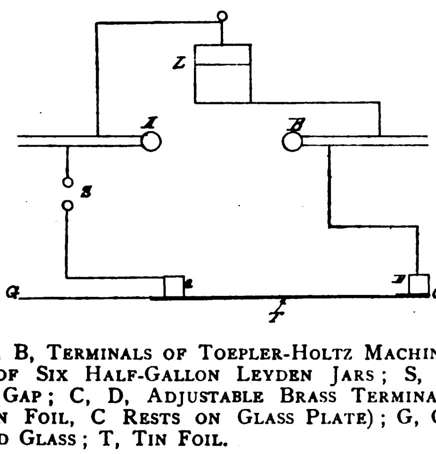

FIG. 2.—A, B, TERMINALS OF TOEPLER-HOLTZ MACHINE; L, BATTERY OF SIX HALF-GALLON LEYDEN JARS; S, ADJUSTABLE SPARK GAP; C, D, ADJUSTABLE BRASS TERMINALS (D RESTS ON TIN FOIL, C RESTS ON GLASS PLATE); G, G, PLATE OF GROUND GLASS; T, TIN FOIL.

between 5 and 6 inches. A condenser connected in series between the terminal and the tinfoil did not materially change the result. Duplicating the tinfoil and glass plate on the opposite side of the terminals from the first and connecting the second tinfoil to the terminal D gave a slightly increased result. Connecting the two plates of foil to the same terminal gave the same result as connecting them to opposite terminals. Additional experiments, with the same arrangement of terminals as detailed above, showed that the striking distance of a given e. m. f. could easily be increased to more than ten times the striking distance of the same e. m. f. directly through air.

It was noted when the arc was first formed with the single plate it followed the surface of the glass very closely and that it usually took a roundabout way between the terminals instead of across in a straight line; also that the arc was rarely formed in the same place twice in succession.

An interesting variation of this experiment was made by placing a wire in a small glass tube with pieces of tinfoil on the outside of the tube, the wire corresponding to the tinfoil plate and the tinfoil to the spark gap terminals, the wire being connected to one of the pieces of tinfoil. The striking distance obtained in this way was about the same as that given by the arrangement first described. When the spark gap terminals were placed inside the tube and the wire on the outside, the tube was instantly shattered by the heat from the arc.

Later some experiments were made, substituting a static

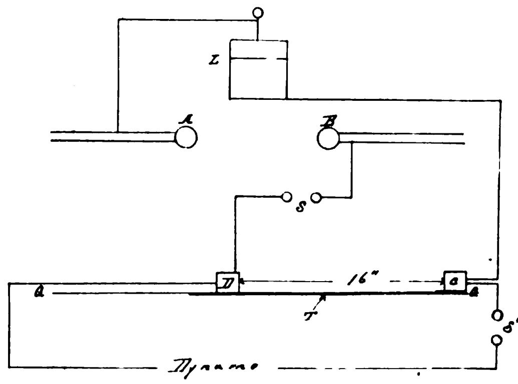

FIG. 3.—A, B, TERMINALS OF TOEPLER-HOLTZ MACHINE; L, BATTERY OF SIX HALF-GALLON LEYDEN JARS; S, ADJUSTABLE SPARK GAP; G, G, PLATE OF GROUND GLASS; T, TIN FOIL; D, C, NON-ARCING LIGHTNING ARRESTER BLOCKS; S, THREE-QUARTER-INCH SPARK GAP.

machine and a bank of Leyden jars in place of the bank of converters. The arrangement of the terminals and the spark gap was the same as before. With this arrangement the striking distance which was obtained from the discharge of the bank of Leyden jars was increased eight or ten times above that which could be obtained when striking directly through air, or along the surface of the glass plate with the connection between the tinfoil and the terminal C broken.

To account for this phenomenon at the time the experiments were made I advanced the following hypothesis: Suppose that the terminal D is positive; C will be negative; the sheet of tinfoil connected to D will be positive and a negative charge will be induced on the surface of the glass plate between the terminals C and D. This charge apparently acts as an extension of the terminal C toward the terminal D, and thereby assists the e. m. f. to strike across.

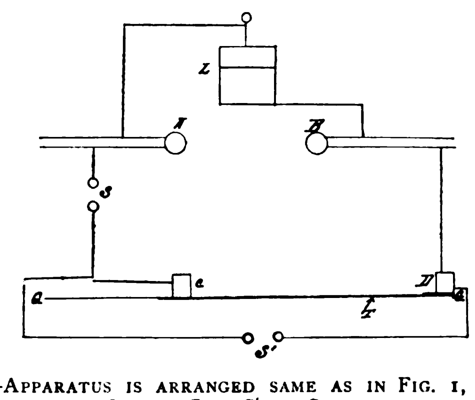

FIG. 4.—APPARATUS IS ARRANGED SAME AS IN FIG. 1, WITH THE ADDITION OF SPARK GAP S' IN SHUNT TO THE TERMINALS C, D.

When this phenomenon was first observed I saw that it might be useful in the construction of lightning arresters, as the apparent resistance of a given length of spark gap might

be greatly decreased, or for a given resistance the length of the gap might be very materially increased.

C. E. SKINNER.

Following Mr. Skinner's suggestion relative to the construction of a lightning arrester with a reduced striking e. m. f., as already described by him, I instituted a series of tests, with the object of constructing, if possible, some simple form of lightning arrester for high potential circuits. The following are the experiments which were made:

In each case the apparatus consisted of a Toepler-Holtz induction machine and a battery of six half-gallon Leyden jars, a plate of ground glass partially covered on the lower and smooth side with tinfoil, which on one end lapped over to the upper side; also various details which will be mentioned in the individual experiments. The connections are all clearly shown in the respective diagrams.

First Experiment.—Variation in length of spark due to different surfaces in its path. See Fig. 2.

The results obtained are given in the following table:

Character of Ground Glass Surface.	Length of Spark.	Distance between Machine Terminals A and B.	Remarks.
Plain	7¾ inches.		
Lead pencil mark	16¾ "		
Plain	12 7/16 "	1⅛ inches.	This measurement was taken after first pencil mark had been removed. Probably, however, particles of plumbago still remained on the glass surface.
Lead pencil mark	17 5/16 "	1 7/16 "	
Lead pencil mark	19 "	1 9/16 "	Marks made heavier.
Plumbago	23¾ "	1⅛ "	
Plumbago	24⅝ "	1⅛ "	

The last figure in the second column, 24⅝ inches, is the maximum spark which was obtainable under the conditions. The length of the plate was such that any further separation of the electrodes C D caused the spark to pass back from C around to T. In the above experiment spark gap S was maintained constant at ⅝ inch. In the third column there is given the distance in inches between the machine terminals A B, which, under the conditions of the test, balanced the distance between C and D; that, is the distance between C D having been fixed, the terminals A B were so adjusted that sparks would indiscriminately pass between A B or C D.

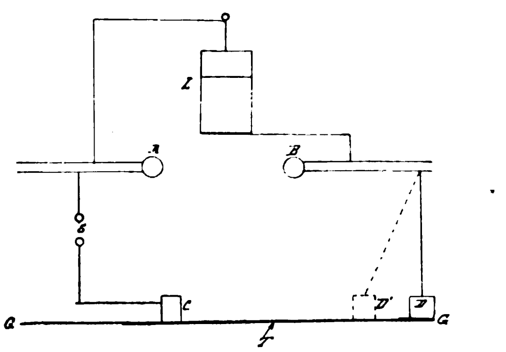

FIG. 5.—APPARATUS IS ARRANGED SAME AS IN FIG. 1, THE TERMINAL D BEING ARRANGED TO SHIFT FROM ITS POSITION ON THE TIN FOIL TO THE POSITION D′ ON THE SURFACE OF THE GLASS PLATE G, G.

Second Experiment.—The terminals of a high potential alternating current circuit were connected to the terminals C D, and the static apparatus removed, the object being to learn what effect the plumbago surface of the glass would have in connection with the high potential alternating current circuit; also to determine what conditions were necessary to prevent brush discharge between the terminals C D.

It was found that with 3,000 volts a heavy brush discharge reached almost the entire distance between the terminals C D. The streak of plumbago over the glass did not seem in any way to affect the path of the discharge, the discharges occurring indiscriminately over the plumbago and clean surfaces as well.

A ¼-inch gap was now placed in the high potential circuit and the voltage lowered by steps to 15,000, at which point there seemed to be a leakage with considerable hissing across the spark gap, but without brush discharge on the plate. At 12,000 volts the leakage ceased altogether. The distance between C and D in the above experiment was maintained at 24⅝ inches.

Third Experiment.—Steps were now taken to determine whether or not it were possible to prevent the dynamo current of a high potential circuit from following the static discharge over the glass plate. In this experiment the terminals C D, Fig. 3, consisted of the lower block of a non-arcing railway lightning arrester cut in two, one half being placed at C, the other half at D; the object of these blocks being, as in the case of the non-arcing railway lightning arrester, to suppress tne formation of the metallic vapors at the electrodes, which are necessary for the formation and maintenance of a dynamo arc.

The results of this experiment are given in the following table:

With and Without the Lightning Arrester Blocks.	Voltage.	Distance between Blocks.	Remarks.
With blocks	12,000	1 inch	Dynamo current followed the discharge.
" "	12,000	3 inches.	No current followed the discharge.
Without blocks.	12,000	4¼ "	Dynamo current followed the discharge.
" "	12,000	6 "	No dynamo current followed the discharge.
" "	15,000	6 "	Dynamo current followed discharge.

From the above table it will be noted that there is a decided difference in the tendency for the dynamo current to follow the discharge when the protecting blocks are used and when they are not used.

Fourth Experiment.—It was next decided to determine the relation existing between the distance C D and a spark gap S′, with rounded electrodes connected in shunt to C D. See Fig. 4. The results are given in the following table:

Length of Spark between C and D.	Equivalent Length of Spark in Air at S′.
2 inches.	20/32 inch.
2½ "	20/32 "
3 "	19/32 "
3½ "	20/32 "
4 "	21/32 "
4½ "	24/32 "
5 "	25/32 "
5½ "	25/32 "
6 "	25/32 "
6½ "	26/32 "
7 "	27/32 "
7½ "	28/32 "

After the last measurement given in the above table no further relation appeared to exist between the two gaps, for having fixed C D at 10 inches the spark would continue to pass between the points C D in preference to the air gap, although C D was lengthened to 17 inches, the air gap remained constant at 29-32 inch. On the other hand, leaving C D constant at 12 inches and having once started the spark at the air gap, even though the latter was lengthened to a far greater extent than in any previous case, the spark continued to cross the air gap .

Fifth Experiment.—To determine the relation between the spark lengths, first, when D is connected to tinfoil, and, second, when there is no such connection. See Fig. 5. The results are given in the following table:

Character of Surface.	Spark Length.	Remarks.
Plain	8½ inches.	D connected.
"	2¼	D not connected.
Plumbago	29¾	D connected.
"	17¼	D not connected.

Twenty-nine and three quarter inches is the longest spark which has been obtained with the static apparatus at hand, namely, six half-gallon Leyden jars and a 6-inch spark Toepler-Holtz machine. The spark was thick and was accompanied by a loud report.

Theory.—While observing the various experiments which have been described, it was noted that light particles dropped on the surface of the glass were repelled. I subsequently analyzed as follows the phenomenon which Mr. Skinner has discovered, taking as a basis for my reasoning the doctrine of the conservation of energy:

A spark in passing from one electrode to another must perform a certain amount of work. In passing through air the work done depends upon the difficulty with which the air is displaced and torn asunder. By experiment it is found that the spark will pass more easily over a surface than through the air. For a given spark length there is therefore less work

performed in forcing the spark over a surface than through the air; in other words, it is easier to separate air from a surface than to separate air from air. The molecules of air are in more intimate contact with each other than are the molecules of air with the molecules of a surface. The addition of plumbago to a surface obviously plays the part of a conductor, and although of not sufficient carrying capacity to conduct the discharge in the sense that a copper wire conducts, still there is conductivity present, and I regard this conducting film, as it were, in the nature of an electric crack through the dielectric. The presence of the metallic coating on the under side of the plate causes repulsion on the upper side. The air repelled from the plate is therefore less dense in the immediate vicinity of the plate than when the under side is not coated with the metal foil. In consequence of this rarefaction of the air over the upper surface of the glass, a spark will perform less work in passing over this surface than when the air has not been thus rarefied. Starting therefore with the work performed by a given spark length in air, the work performed by the same spark length is successively diminished by, first, causing the spark to pass over a surface; second, by smearing the surface with plumbago; and third, by causing a rarefaction of the air in close proximity to the surface.

A high potential lightning arrester has been constructed on the principles described, and although not yet tested in actual practice, the indications are that it will prove effective on circuits up to 30,000 volts. A. J. WURTS.

ASBESTOS.

BY GEORGE HELI GUY.

I.

THERE is probably no product of inorganic nature about which there is so much popular mystery and misconception as asbestos. It is vaguely understood that the principal claim of this remarkable product to attention is that it cannot be consumed by fire, and not infrequently the effect of the mention of asbestos is to carry the hearer back to the far-off Egyptian days when the people of the Pharaohs wrapped their dead in cere-cloths woven from the fibre, in order to preserve them, the body having been first embalmed with aloes and subtle essences, so that no noxious exhalations should disturb a community in which fear of pestilence had become a hereditary instinct. Romantic stories have also come down to us of ancient demonstrations of magic in which asbestos has played the leading part, but the real and vital interest in asbestos centers in the present. It is of more importance to the human race to-day than it has been in the whole range of history. Asbestos twenty-five years ago was practically not known outside the laboratory of the chemist or mineralogist. It now finds its way in one form or another into every workshop where steam is employed. To the question: "What is asbestos?" it is not altogether easy to find an answer. Geologists classify it among the hornblendes. In itself, asbestos is a physical paradox, a mineralogical vegetable, both fibrous and crystalline, elastic yet brittle, a floating stone, but as capable of being carded, spun, and woven as flax, cotton or silk. It is apparently a connecting link between the vegetable and the mineral kingdoms, possessing some of the characteristics of both. In appearance it is light, buoyant, and feathery as thistledown; yet, in its crude state, it is dense and heavy as the solid rock in which it is found. Apparently as perishable as grass, it is yet older than any order of animal or vegetable life on earth. The dissolving influences of time seem to have no effect upon it. The action of unnumbered centuries, by which the hardest rocks known to geologists are worn away, has left no perceptible imprint on the asbestos found embedded in them. While much of its bulk is of the roughest and most gritty materials known, it is really as smooth to the touch as soap or oil. Seemingly as combustible as tow, the fiercest heat cannot consume it, and no known combination of acids will destructively affect the appearance and strength of its fibre, even after days of exposure to its action. It is, in fact, practically indestructible. Its incombustible nature renders it a complete protection from flames, but beyond this most valuable quality, its industrial value is greatly augmented by its non-conduction of heat and electricity, as well as by its important property of practical insolubility in acids.

II.

Asbestos has been found in all quarters of the globe. It comes from Italy, China, Japan, Australia, Spain, Portugal, Hungary, Germany, Russia, the Cape, Central Africa, Canada, Newfoundland, Texas, and other parts of this country, and from Southern and Central America. Scarcely a week passes without the opinion of experts being asked on some new discovery of this mineral substance. Most of the samples are, if not of poor quality, very much inferior to the best. The asbestos of different countries is as varied as the characteristic foliage. The smooth and white, rock-like form of the mineral from the Pyrenees is an absolute contrast to the harsh and brittle tremolite of Servia, unpleasant to handle, with its fine needles like the particles of slag wool, which insidiously penetrate the skin. The Corsican variety is long, soft and silky, its silvery white or pale gold tufts resembling skeins newly wound from a cocoon, while the singular Scandinavian forms are rough and rugged as the country from which they come. It may be said here that while the appearance of asbestos is often very deceptive as a gauge of its commercial value, the points most sought for in the mineral are the length and fineness of fibre, combined with infusibility, toughness and flexibility.

The asbestos generally found in the United States, especially in Virginia, the Carolinas and Texas, also in Staten Island, New Jersey and Pennsylvania, is of the woody form, in appearance like fossilized wood. The veins range in length from a few inches to several feet. The fibre can be split off like soft wood, the appearance being woolly, and when separated it has no strength or cohesion. It cannot be spun nor even pulped. At one time it was thought it might be profitably used as a filler in paper making, but virtually it is of no commercial value. This and kindred classes of asbestos have often been instrumental in the creation of visions of wealth that were never to be realized. A sensation was recently caused by the announcement that a whole mountain of asbestos had been discovered in Oregon. The fibre was reputed to vary from ½ an inch to 2 inches in length, and to be of excellent quality. The discovery was made through the herding of sheep on a mountain side. The value of the find, however, was discounted in the eyes of experts by the supplementary

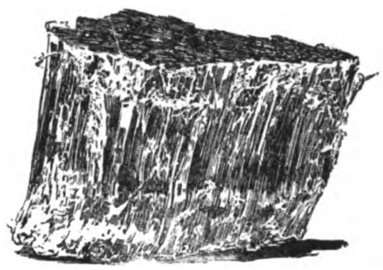

FIG. I.—CANADIAN ASBESTOS.

statement that where the flock had trampled the rock, the asbestos threads showed up like bunches of wool.

III.

Notwithstanding this wide distribution of asbestos, the only varieties which at present appear to demand serious consideration, from a commercial point of view, are the Russian, the South African, the Italian, and the Canadian. The principal claim possessed by the Russian fibre to a place in this quartet is based on the enormous extent of the deposits which have been discovered in East Russia, beyond the Ural Mountains, and Russian Siberia. So far, their specimens have been of comparatively poor quality. The yield is used almost entirely in Europe, where it is mixed with the Canadian for spinning, paper making, and other purposes where an inferior grade can be utilized.

Africa has been stigmatized as "a country of samples," but the fact that she has furnished the world with six tons of diamonds, a thousand tons of ostrich feathers, and with gold and other produce in equally fabulous quantity, cannot fail to have weight in securing a careful consideration for her newer products. Crocidolite, or blue asbestos, occurs in apparently inexhaustible quantities in the Great Orange River Mountains, South Africa, about 700 miles from the Cape of Good Hope. It is found in two forms, fibrous and earthy. The former is of a peculiar lavender blue or leek-green color, possessing long, delicate-looking fibres, which are somewhat elastic and easily divisible. The color is caused by the large proportion of oxide of iron it contains. It is dry and compact, and when fiberized has the look and feel of wool. The fibre varies from half an inch to three inches. Its exceptional tensile strength, which is attributable to its excess of iron, is neutralized (for present purposes), by a corresponding lack of fireproofness. It has but little lime or magnesia, and consequently, when exposed to fire, it weakens and crumbles. For electrical purposes, it is, of course, out of the question. Its chances of coming into the market to any extent, as asbestos, are not promising; but it may for many purposes come to supersede certain other fibres, such as wool, which are much more expensive.

Before the development of the Canadian fields, the Italian asbestos was supreme in the market. For nearly twenty years Italy has been looked to for the best grades of the fibre. From a point on the northern mountain slope of the Susa Valley is taken the floss asbestos fibre, the appearance of which in gas stoves is so familiar. In the same locality is found a fine white powder of asbestos, which serves for paint and other purposes. The mining is carried on at a height of from 6,000 to 10,000 feet above sea level. The temperature is, of course, low, but the inhabitants are hardy and robust, and make willing miners. The works are reached by mule paths, for some distance, but many miles have to be traversed on foot, and the journey to the plain takes from four to five hours. The mode in which the material is brought down the mountain side is by loading it on a sort of toboggan, which slides as easily over the rocks as over snow; and so expert are the inhabitants at this work that two men can bring down eight hundredweight of asbestos in three hours. In searching for asbestos on the Italian hills, the prospector looks in the perpendicular face of the rock for cracks. These may be filled with a white powdery substance, which, after abrasion, assumes a leathery appearance, and is followed, further within the rock, by the true asbestos. The wily art of "salting" is not unknown in these regions. It consists in driving fine asbestos fibre into crevices of the rock, which have been previously primed with the interstratum of leathery consistency, and possibly a foundation of asbestos. In this way many concessions for mining on absolutely barren rock have been sold at high prices. While the Italian asbestos possesses a larger percentage of magnesia, it is poorer in alumina, and holds more water than the Canadian. The Italian, obtained in long fibres—sometimes reaching three feet—cannot be worked with the same ease and evenness as the Canadian. The product is not so uniform, and its greater density and weight render it more expensive and less desirable for general use. A further radical disadvantage is that whilst Canadian asbestos fibre can easily be spun into thread for manufacturing into rope or cloth, Italian cannot be so spun commercially. For manufacturing purposes it is separated into three divisions: 1. The long fibred quality, which is set aside for spinning and weaving. 2. The shorter fibred material, which is made into millboard and paper. 3. The powdery material, part of which is converted into cement, paint, etc., while a considerable quantity is sold to agriculturalists as a manure for vine stocks. It is said to be a preventive of mildew and a destroyer of the phylloxera.

IV.

But the Italian asbestos industry, once so important, is already on the down grade. The difficulties of mining are very great, and unduly increase the cost of production. The asbestos itself, judged by the latest standards, is of inferior quality; it is not easy to spin, and it does not pulp well in the making of paper. The best grade is extremely rare, and its cost of mining and transportation is prohibitive. The supply from the Italian mines is rapidly falling off. As a matter of fact, Canada contains the great asbestos region of the world, in the sense, that while its mines are practically unlimited in productive capacity, the product is of a quality which fully meets the requirements of the newest and most exacting of the innumerable uses that are daily being found for it. This district lies in the Eastern Townships. It covers an area of about 200 miles in length, by 6 or 8 miles wide. Nearly the entire yield is consumed in America. Out of a total export of crude ore from the Dominion, of 3,936 tons in 1888, no less than 3,612 were taken by the United States. Since that time the output has more than doubled; indeed, it has been over 8,000 tons for the last few years. The rock carrying the marketable asbestos is generally, on fresh fracture, a serpentine of some shade of green, in which are contained numerous small particles of iron, both magnetic and chromic. The asbestos, when separated from the rock, shows a glistening, gray, dark-green surface. The fibre, which is easily separable by the fingers, is white and silky and well adapted to the manufacture of textile goods. The method of mining is entirely different from that followed in Italy. It is, in fact, quarrying, more than mining, as the face of the rock is stripped, and the cut is carried down until it reaches the asbestos-carrying serpentine, which is then removed and sent to the top of the quarry. The refuse rock, of which there is always an enormous quantity (possibly twenty or twenty-five tons to one of asbestos), is loaded into cars, run off, and shot over on to the dumping ground. The rock is passed directly into the "cobbing" sheds, where boys chip or "cob" the ore from it. The ore is then put up in bags and stacked away for shipment.

On arriving at the factory, the crude asbestos is placed under a huge roller, which instantly reduces it to a clinging mat-like fibrous mass. This is rapidly passed through a succession of sifters and separators, which tear, strip and clean the fibre until it is ready for the different departments for which it is to be graded. It is then taken up by blowers, and shot in a feathery, snow-like stream into canvas bins. Nothing more beautiful than the material at this stage can be imagined. What a few moments before was dark, sheeny rock, has been transmuted into a white, shining mass of delicate, quivering down.

V.

The process of manufacture is intensely interesting, more especially from the fact that as the industry is constantly entering upon novel phases, new methods of treatment, and special machinery have to be devised. But a description of these would carry this part of the subject to too great a length. It will suffice to say that the asbestos is graded in the bins, according to its length of fibre. No. 1, which is the highest grade, is used for carding, spinning, and weaving. No. 2 is used to some extent for carding, as well as for cement, and for pipe covering, and as a substitute for No. 1 where the material permits of a shorter fibre. No. 3 is used largely in paper, and for many kinds of filters. One of its special uses is for wall plaster. This is a new application which will have a distinct effect in modifying the practice of indoor plastering.

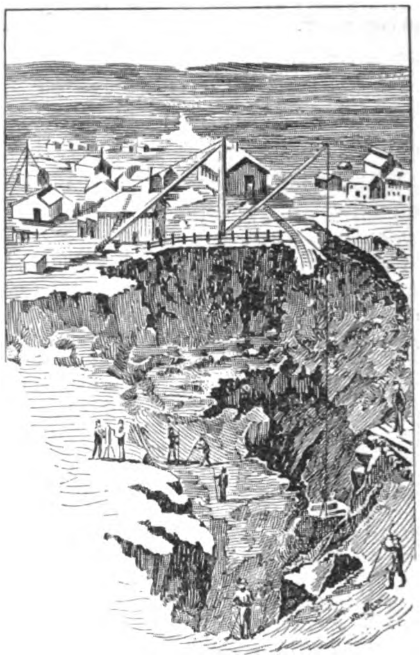

FIG. 2.—ASBESTOS MINING IN CANADA.

Instead of the ordinary tedious and elaborate preparation of studs and strips, and the use of inferior and dust-creating mortar, with its after-scoring, which is necessary to give cohesion to the final coat of plaster of Paris, a single coating of the asbestos is laid on. It has a glossy surface that will not crack, as, while firm, it is perfectly flexible. It can be put on the raw brick; and a room of which the walls have been built in the morning, can, before night, have a smoothly finished interior surface, shining like glass and hard as a rock. A kindred application of asbestos is now coming into vogue in the shape of uninflammable decorations for walls and ceilings. These are used a great deal for the saloons of steamships. They are embossed in very beautiful designs, and can be treated with gold, varnish, lacquers, or any other substance, for the enhancement of their ornamental effect.

The applications of asbestos are now so infinite that it is impossible to enumerate them here; but a few of the more important of them may be mentioned.

Firemen clad in asbestos clothing and masks, as are those of London and Paris, can walk through the hottest flame with comparative impunity. Asbestos fireproof curtains have reduced the mortality of theatre fires in a very appreciable degree. It has been calculated that between 1880 and 1890, the yearly average of persons who perished through fires in theatres, not reckoning the number of lives lost through panics, was 184. Since the introduction of the asbestos curtain, which, at a moment's notice, cuts the stage and scenery off from the auditorium, this mortality has been decreased by one-half. In torpedoes, the difficulty of dealing with the charges of wet gun cotton is overcome by inclosing them in

asbestos, the employment of which has also, in a great measure, brought the dynamite shell to its present efficiency. Asbestos is made into a cloth available for aeronautical purposes. A balloon made of this uninflammable material escapes one of the most terrible dangers to which an ordinarily constructed balloon is liable. Probably one of the first applications of asbestos in this country was to roofing. To buildings covered with this material, the shower of sparks from a neighboring conflagration involves no danger. The output is enormous. It is said that one New York manufacturer makes daily over two miles length of roofing with a special fireproof coating for this purpose. The demand for fireproof paints and coatings is continually increasing. The fact that woodwork can, by its use, be made uninflammable, has come to be an important factor in the insurance of buildings. One of the largest branches of asbestos manufacture is that of sectional cylinders for pipe coverings, for retaining the heat of steam and other pipes, felt protective coverings for boilers, frostproof protections for gas or water pipes, and cement felting, which can be laid on with a trowel, for the covering of steam pipes, boilers or stills. In some of these cases, where it is only necessary to retain the heat, the asbestos is mixed with other substances; but where the protection must be fireproof as well, only asbestos is used. The utility of such covering is well illustrated in the heating system of railway cars. The main pipe from which the individual cars draw their respective heat supplies by side mains, if not covered with asbestos, would lose a large proportion of its caloric from the rapid motion of the car through the air. An interesting innovation in this class of manufacture is asbesto-sponge. It is not generally known that sponge has great powers of fire resistance. The discovery was made accidentally not long ago, and the result was that a consignment of scraps of sponge picked up on the Southern coasts was ordered for experimental purposes. The sponge was finely comminuted and mixed intimately with asbestos fibre. The combination was found so successful for any covering which had to be fireproof as well as heatproof, that the material has become standard. Being full of air cells, it necessarily makes an excellent non-conductor. Another very extensive department in asbestos manufacture is that of packings. Of these there are an infinite number of forms. In these days of high pressures and ocean records, it is of supreme importance to marine engineers that they should have jointing and packing materials on which absolute reliance can be placed. In order to meet modern exigencies every possible form of packing has been constructed, particularly with asbestos and metallic wire, and with asbestos and rubber cores for gland packing. The making of asbestos paper varies from the building up of the thickest millboard to the production of a writing paper, which, from its indestructibility, is invaluable in case of fire for preserving charters, policies, agreements, and other important documents.

VI.

To the electrical engineer, asbestos is absolutely indispensable. Many parts of electrical devices and machinery and wires through which the electric current passes, become heated, and were it not for the electrical insulating and heat-resisting qualities which asbestos possesses, the apparatus would be completely destroyed. A form of asbestos very familiar to the electrical engineer is vulcabeston, which is composed principally of asbestos and rubber vulcanized. It is exceedingly tough and strong, dense, non-absorbent and highly resistant to heat. It possesses great mechanical resistance to blows and pressure, and is readily manufactured in the forms most useful for electrical purposes. Vulvabeston is one of the standard materials for the insulation of dynamos, motors, arc lamps, converters, street car controllers, switches, rheostats, thermostats, and many other forms of electrical apparatus. It is invaluable for the insulation of magnet spools, bushings, washers, commutator rings and sleeves, and controller parts, and for the covering of armatures.

A considerable part of an asbestos factory is devoted to weaving, the asbestos being first drawn into thread for that purpose. Here again is an apparently endless diversity. There is the fireplace curtain blower, which, with an automatic spring roller attachment, takes the place in the frame of the fireplace, of the less sightly sheet iron blower; and filtering cloths for many purposes, from straining molten metal to clarifying saccharine juices in beet root sugar refineries. A cloth is made for straining and filtering acids and alkalies in chemical laboratories. This is specially useful when the liquid to be treated is of a caustic or strongly acid nature. The filter can be thrown in the fire, and after the residual matter has been consumed, the web is as good as new. For filtering purposes generally asbestos has a unique adaptability, and in tropical countries it is held in grateful estimation as a cooler and purifier of water.

The newest departure in the asbestos field is the construction of electrothermic apparatus. The heating effect of the electric current is utilized by embedding the wire in an asbestos sheet or pad. The pad is used by physicians and nurses for maintaining artificial heat in local applications, and is said to be already largely used in hospitals. Another application of the same principle is to car heaters. A sheet of asbestos, with the embedded wires, is clamped between two thin steel plates, and the portable heater thus provided, or a series if need be, is connected to the car circuit quickly and easily. It gives an even and healthy heat and can be so regulated as not to overheat the car.

Although the list of the applications of asbestos is already bewildering, the adaptability of this marvelous product in new fields seems illimitable. In these days of scientific growth and quick resource, it is hard to foretell the scope and destiny of any great industrial innovation; but it may safely be said that the manufacture and utilization of asbestos will for many years to come constitute an industry that will occupy a leading place in the commercial history of this country.

JAPANESE STUDYING ELECTRICITY IN AMERICA.

A special dispatch from San Francisco says: Among the passengers on the steamship China is a special commission from the Mikado of Japan to study into the workings of the electrical power and telephone systems in the United States. The commission is composed of S. Mine, R. Natayama and Y. Wadachi. They spent about two weeks in examining into the telephone and electrical systems of San Francisco, Sacramento, Fresno and other cities, and then proceeded to Eastern cities. They may also visit Europe. They expect to be absent from Japan six or seven months.

"All over our empire now," said Commissioner Mine, "there is great interest in electrical power and in electrical lighting. Electricity has been introduced in several cities, but the government wants it all over the country. It is the same way with telephones. We have seen the value of them, and desire to have them generally adopted. It is our intention to study into the workings of both systems in the United States. We want to generate electricity from the many powerful waterfalls in our country, and use it for electric railways, general power and lighting.

"Wherever we can, we intend to use electricity. It will, according to the ideas of our government, be especially valuable in connection with our various public and private enterprises. It is our desire also to utilize the long-distance telephone in Japan."

MR. FRANK X. CICOTT, manager of the railway department of Pettingell-Andrews Company of Boston and New York, has sailed for Europe by the American liner New York, to be gone about two months.

LETTERS TO THE EDITOR.

THE CHICAGO SMOKE-PREVENTING FURNACE TESTS.

I am very glad to learn that my article on "Comparative Tests of Smoke-Preventing Furnaces," in your issue of March 11, has proved to be of interest to some engineers, as shown by the letter of Mr. C. Doutre, E. E., in your issue of April 8, making inquires concerning the tests.

In reply I would say that on these tests the feed water was not taken from our heater, which delivers the water at a temperature of between 200 and 210 degrees Fahrenheit, on account of the sudden and varying demand for water in the weighing tanks having a tendency to derange the automatic system by which our heater is supplied with water from the hot well. The temperature of the hot well was also lower than usual on account of the small number of engines in service during the tests, the level in the hot well being kept constant by cold water from a valve operated by a float. This low temperature, however, has no effect on the evaporation from and at 212 degrees Fahrenheit, as, of course, the temperature of the feed water was taken into consideration in figuring this.

In regard to the consumption of coal per horse-power per hour, this is per boiler horse-power, of course; if it were figured per engine horse-power it would be a little less than two pounds per horse-power per hour. With this low grade of fuel the cost per horse-power per hour should be considered rather than the weight.

I hope that the above will throw some light on the points raised by Mr. Doutre.

B. R. T. COLLINS,
Engineer of Tests, Chicago Edison Company.

CONTENTS.

ELECTRICITY AND COMPRESSED AIR.

IT is a well established fact that certain ideas in the arts recur in cycles of greater or less period, and one of these is the application of compressed air for motive power purposes generally. It would be rash to deny that compressed air has rendered valuable service in many ways in the past, and that it has still a large field of usefulness, but it is to be regretted that after the long years of experience had with compressed air it should still be put forward by some as an agent for the accomplishment of work for which modern methods have long been demonstrated to be better adapted. As an instance of this character we may recall our recent remarks on a paper read before the American Society of Civil Engineers, in which the author gives it as his opinion that compressed air will be found superior to electricity for power transmission, whether the distance be a thousand feet or twenty miles. We need not trouble ourselves about statements of this character at this late day, but it would appear that compressed air is again being put forward as an active competitor to electricity for street railway work, and it is rumored that the Madison avenue car line in New York City, which has been acquired by the Metropolitan Traction Company, is shortly to be equipped with compressed air motors.

Disregarding for the moment the ulterior reasons that may have dictated this step, there can be little doubt that, considering efficiency alone, compressed air motors cannot compete with electricity directly conveyed by conductors to the car, or by means of storage batteries carried on the car. In the present instance it is proposed to use air compressed into tanks at 2,000 lbs. What the losses would be in such a system is well brought out in the short analysis by Mr. Robert Lundell, which appears on another page. Compressed air as a motive power seems so alluring that many are carried away by it and some recent writers have done much to foster the rosy views which many have held in the past and upon the strength of which many thousands of dollars have been sunk in fruitless attempts. One of the recent writers on this subject is Mr. W. P. Pressinger, who in "Cassier's Magazine" for June, describes the salient features of the latest compressed air street railway motors. Mr. Pressinger devotes considerable space to describing the Hardie motor and the report made thereon by Captain Fiebeger, of the Corps of Engineers, U. S. A. Captain Fiebeger's report is open to many criticisms when viewed from the standpoint of standard street railway traffic. To begin with, the experiments were made with a motor mounted on the tracks of the New York Central Railroad, which statement in itself would be enough to cast a shadow of doubt on their value as a criterion for regular street railway practice, as it is well known that under the normal condition of street railway tracks they call for the consumption on an average of twice the power required for free T-rails which keep clean automatically.

Another advantage claimed for the compressed air motor is that "the weight is spring supported, while in the electric motor the weight of the motor is rigidly attached to the axle." We are afraid that Captain Fiebeger is not thoroughly informed as to the more modern methods in electric railway practice. We could name several electric motors which do not rest on the car axles. While it is true that a large number of this type are still in use it is only a question of time when they will disappear. We are also told that electric cars require an excessive power in the motors from the fact that two motors are employed which do not work synchronously. This criticism brings up the old question as to the power required to drive electric cars. Beginning with two 7½ horse-power machines, used by Mr. Sprague in Richmond, the power has gradually increased until the present normal equipment is two 25 horse-power motors to each car. No one acquainted with street railway practice need be told that an ordinary street car, when running at speed, requires anything like the full capacity of its motor equipment, but some writers on the subject fail to

fully grasp the fact that the substitution for electricity has created a demand for higher speed than the horse was able to furnish. If the public would be satisfied with a slow, gradual start, permitting the car to reach its normal speed within the space of a block, one-half the motor equipment now applied would be ample; but unfortunately such is not the case. The motorman who does not now bring up his car to full speed within three or four car lengths could not maintain schedule time, and would in all probability lose his position. These conditions exist, no matter what the nature of the power applied, at least so far as this country is concerned. It is hardly fair to compare foreign practice to that of the United States on these lines. Abroad cars are considered fully loaded which we consider half full. In addition, the public abroad is quite satisfied with speeds such as would not be tolerated by the American public. As a consequence, the power consumed by cars operated by compressed air abroad must be largely modified when applied to conditions existing in the United States.

With all these facts before us, we cannot believe that the Metropolitan Traction Company, even if it installs the ten or dozen compressed air cars on the Madison avenue line, intends to employ this system generally for its new work in New York City. We do not, in fact, look upon it as an experiment in the true sense of the word, but venture to believe that it is rather a device to gain time, pending further investigation for the introduction of electricity. As our readers are aware, several cars operated by storage batteries have been operated on this line during the past winter. At the same time the Metropolitan Traction Company has had an opportunity to study the workings of the Lenox avenue conduit. The latter, we understand, has not given entire satisfaction, but the defects, such as they are, we believe, can be remedied. On the other hand, other underground systems, several of which are now in practical operation both here and in Washington, will afford ample opportunity for observation, and when the time comes for actual work we have no fear but that electricity in one form or other will be adopted as the motive power.

ALTERNATE CURRENT ARC LIGHTING.

THE demand for systems of electrical distribution that shall be sufficiently flexible to operate any kind of load from the mains supplied by one type of generators has led within the last few years to some remarkable modifications, especially in the field of alternate current working. The use of arc and incandescent lamps and motors from the same current supply is perfectly feasible and in common every-day practice in direct current stations, but in alternating current stations the problem in regard to arc lighting may be said to be still in a somewhat unsettled condition, although such stations are supplying arc lamps which require the use of more or less inefficient devices. The use of the old direct current, series machines was almost universal for arc lighting until very recently, and probably more than 90 per cent. of the public arc lighting in this country is still done with series machines. The use of two or more kinds of machines in a station is incompatible with the highest economy, and as it is apparent from experience that any successful station must be prepared to supply current for all purposes, the old line of series machines will gradually disappear, as they already have to some extent on direct current constant potential systems.

One method of supplying arc lights from alternating stations is to run a special arc machine from a synchronous motor connected to the alternating circuit. This is evidently an inefficient method. Another is to run alternating current arc lamps from a transformer, either one or several lamps to one transformer. Another method for alternating current stations is arc lighting by means of rectifiers, which method has come into use in England during the last three or four years, although the principle has been known since the earliest time of arc lighting. The first arc lights used in the French lighthouses were run from alternators fitted with commutators, and this is practically rectified current arc lighting. The result of some efficiency tests with rectifiers and alternators has been found to be as high as 80 per cent. for a 55-light unit, which is considerably higher than was obtained from a direct current machine of the same capacity in a comparative test. But sixty lights appears to be the limit to which rectifiers have reached and even with this size there is heavy sparking at the commutators. This size, however, will hardly satisfy the conditions of American practice, as both economy and convenience demand the use of units of double this size in many places. Arc lamps when used with rectifiers also require some modifications in design, as the regulation is more sluggish than with direct current arcs. While this solution may be of advantage in special cases, it does not appear to meet the requirements of a series circuit of 5,000 or 6,000 volts, which is frequently necessary in lighting outlying districts economically. The most satisfactory solution of this alternate current problem would probably lie in the production of a series alternating arc lamp whose luminous efficiency would reach that of the continuous current arc.

DRAWBAUGH AGAIN.

IF persistency be a virtue, then the palm for this valuable faculty must be awarded to Mr. Drawbaugh and his associates. One would have supposed that a decision of the United States Supreme Court would suffice to put an end to all claims and disputes, but evidently Mr. Drawbaugh and his coadjutors believe otherwise. As noted on another page, the Senate Committee on Patents last week made a favorable report on a bill for the relief of Drawbaugh, so as to permit the issuance to him of his original patent applications of some fifteen years ago, for the microphone transmitter, etc. These Drawbaugh patents cover practically the main principles used in all modern telephonic apparatus, and if the bill be allowed to pass and the patents to issue, they would occupy practically the same ground now covered by the governing patents owned by the American Bell Telephone Company. It is true that the bill grants immunity to all users of telephonic apparatus prior to the proposed issuance of the Drawbaugh patents, but this proviso must, of course, cut a very small figure in the end. The issuance of these patents would at once place the American Bell Telephone Company again in a position where it would have to fight for existence, and if we may judge by the past, it will enter the fray with a light heart. Viewed from the standpoint of the public, however, the issuance of these patents to Drawbaugh would create another monopoly, which would without doubt be even more distasteful than that of the Bell company, and if we mistake not the country is in no mood for the granting of further privileges in this field. Indeed, the whole proposition embodied in the proposed bill for relief to Drawbaugh strikes us as being too preposterous to require any serious consideration.

THE HORSELESS VEHICLE COMPETITION.

THE competitive test of horseless vehicles which took place in New York on Decoration Day cannot fail to leave the impression that considerable remains to be accomplished before this style of locomotion can supersede the horse as a motive power. There were no electric carriages in this exhibition, and, so, as far as this special test is concerned, no comparisons can be drawn between electricity and the gasolene and other liquid fuel engines, which took part in this event. But it is noteworthy that the engine-driven vehicles which were in this competition, with but one exception, returned from the trip to Irvington in a more or less dilapidated condition.

Electric Lighting.

THE CONTROLLABLE JUNCTION BOXES AND FEEDER SWITCHING SYSTEM OF THE NEW YORK EDISON CO.

WHILE the extended description of the stations of the Edison Electric Illuminating Company, of New York, which appeared in our issue of January 8, gave the salient features of the work of that admirably equipped organization, many interesting details were of necessity omitted for lack of space. Indeed, to have dwelt even briefly on all the numerous smaller, secondary operating methods and apparatus would have involved the writing of a respectable volume, instead of the comparatively few pages which formed the limits of our article. Nevertheless, some of these smaller details have important influence on the economy of operation, and one among these, which has been found to work particularly well in p[illegible] is the system of controllable junction boxes, which m[illegible] possible to switch underground circuits together, or apart, by switches located at the stations. The system of employing these controllable boxes is due to Mr. R. R. Bowker, first vice-president of the company, who devised the general plan, and Mr. John Van Vleck, its constructing engineer, who invented the mechanism of the special junction boxes, and as it has a general and useful application, we have deemed it well to describe it in some detail.

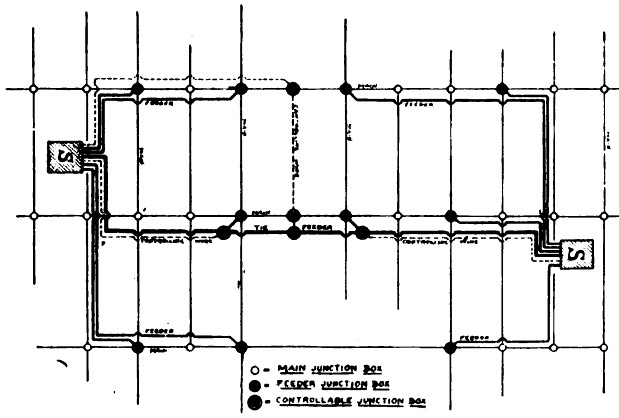

Fig. 1.—The Bowker Feeder Switching System.

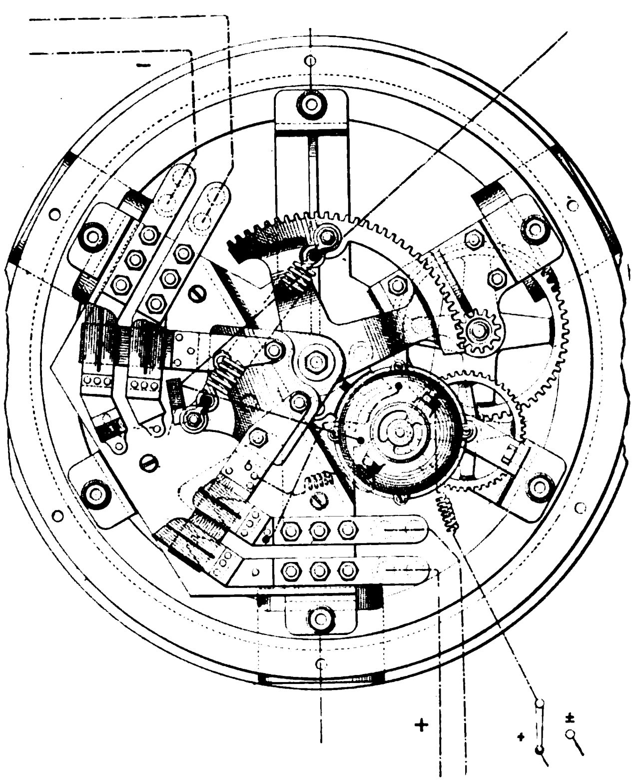

Fig. 2.— [T]he Van Vleck Controllable Junction Box.

The most important of its functions consists in the insertion of controllable boxes in the line of a tie feeder between two stations, so that when the tie line is not used as a means to transmit energy directly from one station to another it can be connected at will to one or more points of the distributing system of mains, thus enabling the tie feeder, that would otherwise lie idle, to be used as a regular distributing feeder in each direction from both stations.

Another application consists in the insertion of the controllable boxes directly in the lines connecting one district with another, which districts might each be supplied by separate stations; in this way one district can easily be electrically separated from the other in case it should become desirable to make such a disconnection.

The above applications can perhaps be better understood by referring to diagram, Fig. 1, which shows two branch disconnective boxes inserted in a tie feeder, one box being controlled from one station and the other box from another; but the boxes as made can both be controlled from one station if desired.

The diagram also shows straightway disconnective boxes inserted in the mains connecting the two districts supplied by separate stations and also in the tie feeder connecting the two stations; these boxes can, if desired, all be operated from one of the stations, or they can all be operated separately if desired.

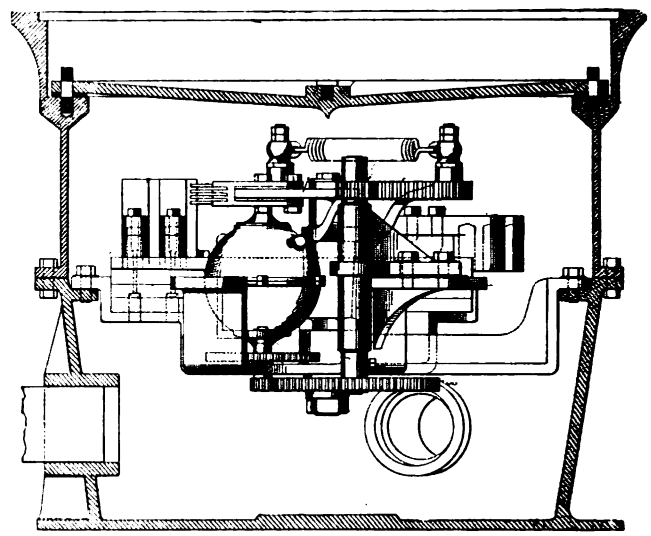

Fig. 3.—The Van Vleck Controllable Junction Box.

A further application consists in switching feeders or mains on at particular points of the system at certain times when an increased supply of current might be needed at one place and not at another, as, for instance, the charging of storage batteries located at a distance from a generating station, when such charging might make it desirable to charge at night from certain feeders that would otherwise be employed at the time of maximum load.

The various applications of the box are, in fact, quite numerous, and it is expected that the use of controllable boxes will materially assist in the economical and satisfactory distribution of low tension energy.

The details of the box itself, are illustrated in two views in Figs. 2 and 3, and its principle will here be briefly described. The box is constructed so as to break or switch apart a straight line running through it; or else, it can be made to break a branch line emanating from it. In either case, the box contains a double-pole knife blade switch which is operated by a 1-6 horse-power Lundell motor inclosed in the box. The field of the motor is connected constantly in one direction across 120 volts, while one end of the armature circuit is connected to one of the movable switch blades, the other end being connected to a two-way switch placed at the station or some other point of control. The connection is made by employing a convenient pressure wire that might otherwise be used as a neutral pressure wire, and, therefore, not necessary for the reading of pressure.

On throwing the two-way controlling switch in the station an opposite potential is thrown across the armature, which causes the motor to revolve, opens the main switch in the box

and the blade connected to the box end of the armature circuit is brought in contact with a terminal of the same potential as that of the other, or station, end of the armature circuit, thus bringing the armature to rest.

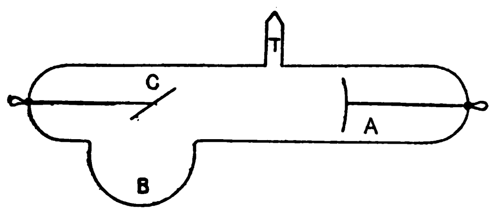
When it is desired to reconnect the box, the two-way switch in the station is thrown over, so as to bring an opposite potential again across the armature circuit with a reversed polarity, so that the armature is caused to revolve in an apposite direction, and the main switch in the box is closed. This operation can, of course, be repeated any number of times.

By connecting lamps or a galvanometer in the circuit of the controlling pressure wire at the station, an indication will be given as to whether the motor has operated, so that no doubt will exist as to whether the switching operation in the box has been successfully accomplished.

It might be of interest to note that one of these boxes has been successfully operated over 8,000 times in order to establish the general reliability of the mechanism.

AN IMPROVED CROOKES TUBE.

Of all the forms of tube that we have tried, say Messrs. Hutchins and Collins, of Bowdoin College, in the "Scientific American," the one shown in the annexed diagram is the most effective. Here the anode, C, is an inclined plate of thin platinum. This is placed at or beyond the focal point of the cathode, A. This piece of platinum becomes red hot, and is, as far as can be judged, the source of the ray. It is a curious fact that the anode, C, if made in the form of a thin plate, may nearly fill the tube without in any way obstructing the passage of the rays out at the bulb. The bulb is filled with an intense green fluorescence, and sparks can be drawn from it by approaching the finger.



Novel Form of X-Ray Tube.

Not only do these tubes give remarkable results in the way of intensity of rays, but also extremely fine definition.

The cellular structure of the bones is clearly brought out and the course of the tendons can be traced along the arm. Good pictures of the bones of the fingers can be obtained in from five to thirty seconds, and of the hand and wrist in from one to ten minutes.

X-RAY TUBE PHENOMENA.

Writing on his work with X-ray tubes in "Nature," Mr. J. W. Gifford gives the following experience:

"At one of my demonstrations two tubes failed to act. They were both of the kind which depend for their action on a piece of platinum placed within, and from which after bombardment by cathode rays the Röntgen rays take origin. A glance at the tubes showed that owing to the unusual strength of spark the platinums within them were red-hot at the point of impact. Before the demonstration the tubes had been in good working order. I considered they had broken down, but, on returning home, tried them with the spark from my own apparatus, with which they had before answered well. I was somewhat astonished to find them giving off Röntgen rays rather more freely than when first tried. This tends to show that Röntgen rays are not given off by platinum heated above a certain temperature. I think this has already been suggested, but I have not seen it corroborated.

"Following up the idea of reinforcing the effect of the Röntgen rays by placing a fluorescent screen under a sensitive film on celluloid, the celluloid side being next the screen to prevent 'grain,' and having tried screens of barium platino-cyanide, potassium platino-cyanide, calcium tungstate, natural scheelite, artificial scheelite (Edison's), fluorspar and calcium fluoride, I find that potassium platino-cyanide and artificial scheelite alone produce any effect through celluloid. Barium platinocyanide, placed underneath, gave no effect either in contact with the sensitive film itself or through celluloid, but the films were not sensitive to yellow, and this salt gives yellow fluorescence. The effect with potassium platino-cyanide was decidedly the best."

THE ACTION OF ROENTGEN RAYS AND ULTRA-VIOLET LIGHT ON ELECTRIC SPARKS.

In a recent number of the proceedings of the Accademia dei Lincei, Messrs. Sella and Majorana describe a series of experiments on the above subject, of which they give an abstract in a letter to "Nature:"

"We had formerly found that the sparking distance between two electrodes, in a shunt-circuit on the discharge of an induction coil, which illuminates a Crookes tube, is strongly diminished if the Röntgen rays sent from the tube fall upon the positive electrode. The phenomenon is very interesting, as it is the reverse of the phenomenon discovered by Hertz, in which the ultra-violet light acts on the sparking distance in lengthening it when falling on the negative pole. On subsequent experiments, we found that when the sparking distance was the same as that used with Röntgen rays, the ultra-violet light acted exactly in the same way, and the passive pole—so to say—was then the positive one.

"So far we had succeeded in reversing the phenomenon discovered by Hertz, and further investigated by Wiedemann, Ebert, Elster and Geitel, and had shown the parallelism of the two radiations as to their impeditive action on the spark. But on diminishing the sparking distance, when the ultra-violet light has a facilitating action, we have shown that the Röntgen rays would provoke the passing of the spark. In the last case the passive pole—i. e., on which the radiation must fall—is in both cases the negative.

"So taking as electrodes two spheres of amalgamated brass, 52 mm. in diameter, when the sparking distance was below 30 mm., the Röntgen rays and the ultra-violet light provoke the passing of the spark when falling on the negative electrode. When, on the contrary, the distance was more than 30 mm., both radiations act in an impeditive way when falling on the positive pole."

AN X-RAY METER.

The peculiar glow exhibited by a "focus" tube working well furnishes a good criterion of efficiency as regards Röntgen rays. A more definite means of comparing the actinic power of the radiation has been produced by Messrs. Reynolds and Branson, Leeds. A small quadrant of aluminum is constructed in concentric terraces, ranging from one millimetre to ten millimetres in thickness. By holding this quadrant between an excited Crookes tube and a phosphorescent screen, the thickness of aluminum which the rays are capable of traversing can be seen upon the screen; or, by substituting a sensitive plate for the screen, the effect may be photographed. The "X-ray meter," as the quadrant is called, thus furnishes an easy means of comparing the intensity of Röntgen rays emitted by different tubes and by the same tubes at different times.

LORD KELVIN ON LAMPS.

Lord Kelvin has been giving evidence before the House of Commons Committee on the question of the Petroleum Acts in connection with the public safety. He thinks the sale of paraffin for ordinary use of a lower flashing point than 130 degrees, open test, ought to be prohibited by law, but does not think it would be wise to introduce legislative restrictions on the manufacture and sale of lamps. In fact, so far as the petroleum lamp is concerned, he despairs of introducing safety by legislation. It seems that the most dangerous lamps are not in poor houses, but in fine drawing rooms. Some of those on tall stands with large crystal reservoirs would make a very bad accident if they fell over. On a balance of evils, Lord Kelvin prefers metal to glass reservoirs, but jokingly suggested that the ideal would be an aluminum reservoir with a Röntgen ray to see inside of it.

ELECTRICAL DISPLAYS AT MOSCOW.

The electric illuminations of the Kremlin are reported to have been a great success. Some interesting particulars as to the preparations for the display appeared recently in the "Novo Vremya": "Electricity will be freely called into play. For several months past military electricians and sailors have been actively employed in fixing electric lamps on the tower of Ivan Veliki and other buildings in the Kremlin; 6,000 lamps are arranged outside that tower, 10,000 more on the walls of the Palace fortress, and 8,000 on the arsenal and barracks.

The electric wires that will supply these 24,000 lamps are ten versts in extent. There will also be 200,000 colored lamps lit by oil, while the façade of the Kremlin facing the Red Square will be illuminated by means of gas. The Tainitskaia tower will be transformed into a cascade lit up by electricity, the water falling the whole height of the tower on to the quay of the river."

X-RAYS WIN A DAMAGE SUIT.

X-rays have recently won a damage suit in England in a case which Miss Gladys Ffolliett, an actress, brought against the Nottingham Theater Company. The plaintiff alleged that she had injured her foot because of a faulty staircase in the theater. When the defendants denied this Miss Ffolliett had the bones subjected to X-rays by Professor Ramsay, produced the result in court, and the jury decided in her favor.

THE SCHNABEL LAMP.

Mr. Rudolf Schnabel, of Dresden, has written to the "Elektrotechnischer Anzeiger" to say that he has discovered a new material which will be of great service in electric lighting work. No details are given as to the constitution of the material, but it appears to be a powder. The weight used is a quarter of a gramme, and the price of it $1.50 a kilogramme. The lamp takes the form of a marble slab, with a groove and a shallow cavity to receive the powder. Carbon leads are used. It is stated that sixteen watts (four amperes at four volts) give a power of twenty candles; that the light is whiter than that of an incandescent lamp, but contains more yellow than violet rays. The temperature of the incandescing material is such that iridium wire at once melts and is vaporized within three or four minutes. Editorially, the "Elektrotechnischer Anzeiger" points out that the new lamp claims an efficiency of .8 watt per candle as compared with 2½ to 3 watts for an ordinary incandescent lamp, and makes the obvious remark that a low-potential lamp of this kind could not be used in parallel on any existing systems. It is added that the discovery of Mr. Schnabel will be one of far-reaching importance if the particulars given above can be maintained; the life of the lamp is reasonably long, and the cost of installation not too great. The result of trials of the lamp is still to be awaited.

PERSONAL.

MR. T. C. MARTIN, editor of The Electrical Engineer, left on Saturday, June 6, by the "City of Rome" for Glasgow, where he will represent, by appointment, the American Institute of Electrical Engineers and the National Electric Light Association at the jubilee of Lord Kelvin, as Professor of Natural Philosophy in the University of Glasgow. On June 19 Mr. Martin is to lecture by invitation before the Royal Institution in London, on the Electrical Utilization of Niagara.

MR. E. A. BARNES, of the Fort Wayne Electric Corporation, seized the opportunity to attend the exposition and at the same time look up old acquaintances in New York during the last two weeks.

OBITUARY.

HENRY C. CRANSTON.

Henry C. Cranston, banker, and president of the Providence Telephone Company, died suddenly last month, aged 70 years. He had charge of the first telegraph office in Providence, and later was attached to the Mexican Boundary Commission. In 1864, after having been in the employ of the Providence National Bank for several years, he embarked in the banking business for himself. He was actively interested in the development of the telephone service in Providence.

LITERATURE.

COX'S PULLEY AND GEARING COMPUTER, Cox Computer Company, New York. Price, $1. This is a very handy device for computing the sizes of pulleys and gearing when the number of revolutions, diameter, or number of both gear teeth and belt speed are known. The computer is accompanied by full instructions as to its use. It makes a very handy folder, printed on stiff cardboard.

TELEPHONY AND TELEGRAPHY.

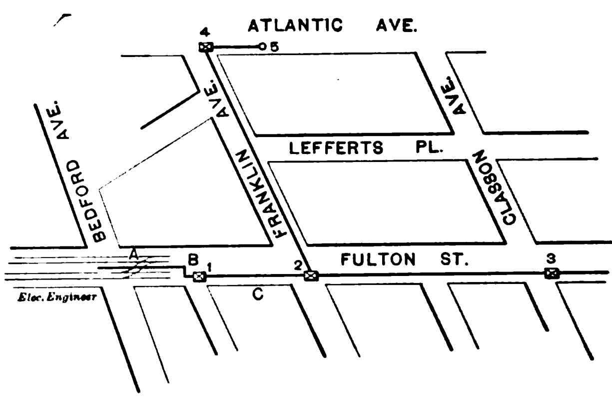
MANHOLE EXPLOSIONS AND THEIR REMEDY.

BY A. E. DOBBS.

EXPLOSIONS occurred in four manholes of the New York and New Jersey Telephone Company's system in Brooklyn about May 1, and in each instance manhole covers weighing from 400 to 700 pounds were blown out. In one case a cover weighing 600 pounds was thrown as high as the elevated railroad structure, against which it was broken. The explosions occurred at Classon avenue and Fulton street, at Franklin and Atlantic avenues, at Franklin avenue and Fulton street, and at Fulton street and Bedford avenue.

The part of the occurrence of interest to electrical men is the cause of the explosions and what means can be taken to prevent them. The cause of the explosion was easily found. Fulton street in this section is being repaved and the trolley companies are also taking advantage of this to make repairs on their tracks. At Fulton street and Bedford avenue a temporary crossover had been put in to enable the cars to cross from one track to the other. At the same place the telephone cable—104 conductors lead covered—is hung midway between the two tracks upon the elevated railway structure, which is also used to support the trolley wires as well as electric light wires. Where the crossover had been put in, A, of the accompanying diagram, a pole was swung from one track to the other in close proximity to the telephone cable. Conductors, when crossing this switch, had been warned to pull down the trolley pole, but one of them forgot it and a bent trolley pole made contact from the wire to the cable, and of course as there is always a little gas in the manholes which had been increased by the disturbance of the streets, an explosion followed.

At the point marked B the cable leaves the elevated structure and goes into the underground ducts through an iron pipe.



The pipe lies loosely against an iron pillar and is not in good contact with it, as was proved by the fact that an arc had been formed, which, judging by appearances, must have taken at least five amperes, thus showing the resistance between it and the elevated road to be about 100 ohms.

As the cable where it entered the pipe was insulated from it by means of rubber hose, etc., and the pipe doubtless painted on the inside, it requires no shrewd guessing to suppose that considerable of a spark passed from the cable to the end of the pipe in the manhole.

But this iron pipe only took care of five or six amperes and considerably more than this must have come from the trolley cross.

From the point 1 in the diagram the cable goes to the other manholes in creosoted wooden ducts, which are a very good insulator for such heavy currents, even though they do ring grounded to a magneto. At manhole No. 2 the cable divides, part of it going to No. 3 and part to No. 4. At manhole No. 2 also there are several cables with well-soldered connections all bound together with a copper wire, but they were not grounded in this manhole except that the copper wire used for connecting them together was lying loosely against a gas main. One of the cables was also in loose contact with this gas main, just close enough to make a good spark if there were several hundred volts potential between the pipe and the cable, as there undoubtedly was, for this cable was not grounded except for the light ground it got from the wooden ducts, while the gas pipe was well grounded, and lying in such close proximity to the tracks, was probably connected to them also.

From 2 to 4 the cable was also laid in creosoted conduit, but from 4 to the junction pole an iron pipe was used, and the difference of potential between this and the comparatively weak ground on the cable must have been considerable. There were very faint traces of an arc between the cable to the pipe, but with the potential carried one-fifth of an ampere would be enough for this.

The Fault.—This cable, though strung for some distance under the elevated structure, was carefully insulated from it and the only grounding the cable received was from the creosoted ducts and from other cables similarly situated. In the aggregate, of course, the ground was very good for weak currents, but the potential difference between different parts of the system must greatly facilitate electrolysis.

The Remedy.—When it is necessary to ground a cable or conductor, the work cannot be too well done. Make the connection to gas or water pipes in its immediate vicinity so thorough that there can be no more than one volt potential difference between them and the cable.

When cables are strung under the elevated roads, connect them to the suspension wire every thousand feet. Had this plan been followed in the above case the current would have been largely shunted to the elevated road instead of into the manholes, and had the cables been grounded at the manholes as already suggested there could have been no spark. Moreover, the season for thunderstorms is approaching and it requires no expert guessing to anticipate still more of these explosions.

Again, if a cable must be insulated, as in creosoted conduits, see to it that the insulation is maintained. If you have the cable laid in wooden ducts do not change from these to iron pipe, or if you must use iron pipe see that the cable is wrapped with something like tarred cloth or rubber hose that will insulate it. If this plan had been followed in Brooklyn the current would have distributed itself so gradually that there would not have been a spark at any one point. In the above case, also, if there are gas, steam or water pipes in the same manholes, see to it that the cable does not touch any of them.

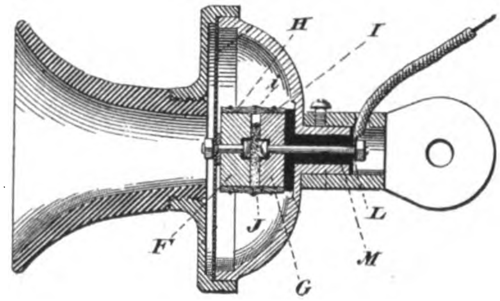
It might also be pertinent to suggest right here that perhaps manhole coverings could be made with openings that would allow the gas to escape and the bottom of the manhole to be drained into the sewer. Of course a great deal of dirt would get into a box of this kind and the Board of Health might object to the gas, but the dirt could be cleaned out once or twice a year and the gas would probably not escape in quantities large enough to be objectionable. It is but just to the engineering talent of the N. Y. and N. J. Telephone Company to say that these conduits were built long before the trolley lines were erected, and that all this trouble with electrolysis and manhole explosions could not well have been anticipated.

PROTECTING TELEGRAPH AND TELEPHONE WIRES FROM TROLLEY CONTACTS.

AN article in the "Elektrotechnische Zeitschrift" describes an apparatus tried on the Zwickau Electric Railway, in Germany. The trolley wires of the up and down lines of the railway, where they are crossed by telephone and telegraph wires, are protected by guard wires running parallel to the trolley wires and at some distance above them. In most cases of fallen wire this would be sufficient to prevent a contact, as the fallen wire would hang in bights from the guard wires and would be well clear of the trolley wires. If, however, the breakage occurred close overhead so that there was a loose end to be dealt with, this would not be the case, since the loose end would hang straight down from the guard wire to the tram wire, and if it fused there is nothing to determine at which point it would go. Moreover, under the influence of the wind or anything causing the loose end to swing, there would be the contingency of momentary contacts occurring of a very troublesome character. In the Zwickau arrangement the two guard wires are connected by a cross span wire which goes to the coil of an electromagnet and thence to the rails, constituting the return of the railway circuit. A wire also goes from the overhead trolley wire to this, the earthing wire, at some point between the electromagnet and the rails. This wire, of course, puts the trolley wire to earth, and the circuit is accordingly broken in the neighborhood of the electromagnet. When, however, the latter is excited and attracts its armature, this latter releases a falling piece, which completes the circuit. Any slight current from the telegraph or telephone wire would be too weak to affect the armature, but even a momentary contact, which sends the heavy current of the trolley wire through the short length of fallen wire to the guard wire and thence to the electromagnet, at once puts the trolley wire to earth until some one comes along and replaces the falling piece. It is stated that the trials made at Zwickau proved exceedingly satisfactory.

SUTTON'S MICROPHONE TRANSMITTER.

THE accompanying engraving illustrates a novel form of telephone transmitter invented by Mr. George W. Sutton. The talking parts of the telephone are inclosed in a case of the usual pattern. The variable pressure parts, shown in cross section, comprise a pair of carbon buttons, F G, which are placed opposite each other. These are surrounded by a sleeve or envelope of cloth, H I, whose edges are frayed. The edges serve to keep the buttons a small distance apart to form a chamber, J, which contains granular carbon. One of the buttons, F, is carried on the diaphragm, being electrically connected to it by a screw whose head is insulated from the button. The other electrode is supported on a metallic bolt, L, which passes through it. The bolt is surrounded by an insulating sleeve, M, set in the back of the casing, and constitutes one terminal of the telephone, while the casing itself is the other terminal.



THE SUTTON TRANSMITTER.

The object of this invention has been to produce a delicate, easily adjusted telephone, which would be suitable for either short or long distance working.

A BILL FOR THE RELIEF OF DRAWBAUGH.

On June 3 the Senate Committee on Patents, by a vote of 4 to 3, made a favorable report on the bill for the relief of Daniel Drawbaugh. This bill directs the Commissioner of Patents to issue to Daniel Drawbaugh a patent or patents for the inventions of improvements in telephony described and claimed in pending applications filed by Drawbaugh in the Patent Office at various times from 1880 until 1884, notwithstanding that said inventions may have been in use or on sale for more than two years prior to the date of the filing of Drawbaugh's original application of July 26, 1880. These patents, when issued, are to have the same effect as though no delay had occurred in presenting or prosecution therefor, and each patent when so issued is to be good in law to secure to the owner the sole right during its term to the exclusive use, make, and sale of such patent invention. A proviso gives all persons having apparatus containing any of these inventions in use at the time of issuing such patent the right to continue the use of such apparatus without charge or molestation; and no one is to be liable to Drawbaugh for any manufacture, use, or sale of Drawbaugh's inventions occurring prior to the issuance of the patent or patents authorized in the bill.

In an interview, Mr. J. R. Bartlett, president of the Drawbaugh Telephone and Telegraph Company, is quoted as follows:

"It will permit the issue to Drawbaugh of fundamental patents for the microphone, thereby transferring the control of the long distance telephone from the Bell company under the Berliner patent to the Drawbaugh company. The public will not be burdened by an extended control of the telephone, as the Berliner patent now covers the forms of telephone embraced in the bill, and this Berliner patent is owned by the Bell company. The Government has a suit pending to cancel it upon the ground of fraud. Drawbaugh's priority in the invention of the telephone has long been known and abundantly established, and the Government has a second suit pending against the Bell company in which this priority has been plainly demonstrated. Drawbaugh has been prevented from obtaining these fundamental patents only by a slight technicality, which was set up against him through the influence of

the Bell company, and it is to relieve Drawbaugh of this technicality that the present bill has been introduced. Opposition was made before the Senate Committee on Patents by the counsel of the Bell company, and an exhaustive argument was presented to show that Drawbaugh was not entitled to any consideration, but the merits of his claims were so apparent that the Patent Committee reported the bill favorably. The Bell company has enjoyed many years of prosperity, based on the rights belonging to another, but Congress has at last undertaken to right this wrong by the enactment of a law, which, while moderate and reasonable in its terms, will secure to Daniel Drawbaugh the rights that belong to him."

CONSOLIDATION OF INDEPENDENT TELEPHONE COMPANIES.

Representatives of thirty independent telephone companies doing business in Eastern Ohio, West Virginia and Western Pennsylvania, met in Pittsburg on June 3 and consolidated under the name of the Interstate and Local Telephone Association, for the purpose of competing with the Bell Company. The several companies represented a capital of about $750,000, and have over 10,000 instruments in use. D. C. Ogden, of Greensburg, Pa., was elected president of the new company; A. V. Diveley, Altoona, vice-president; Burt Hubbell, Pittsburg, secretary, and D. D. Jamieson, New Castle, Pa., treasurer. The new company proposes to furnish telephones to subscribers for less than half the Bell Company's charges.

REPORTING OF THE ST. LOUIS CONVENTION.

Preparations for handling the telegraphic reports of the St. Louis Convention are unusually complete. The Western Union Telegraph Company has assigned its most expert operators from the various large offices throughout the country to the convention work, and the wire facilities will be ample for any emergency.

There will be one change in the telegraph service in this year's convention. The telegraph companies, at the solicitation of the newspapers, will send out no bulletins from the Convention Hall until balloting begins. After that they will simply announce the result of the ballots.

EDUCATIONAL.

THE ROSE POLYTECHNIC.

The Rose Polytechnic Institute, of Terre Haute, Ind., has just issued its fourteenth annual catalogue containing the courses of study and plan of instruction. A separate illustrated catalogue is issued for the department of electrical engineering, showing views of the electrical laboratory, standardizing room, a portion of the generating plant and the machine shop of the Institute. The course in electricity commences in the middle of the sophomore year and throughout the course the work is largely done in the laboratory. Together with the study of the theory of electricity, comes the practical experimental verification.

The carrying on of this course requires the provision of a complete equipment of instruments of precision for investigational work, and other appliances for practice in technical operations, all of which are to be found in its well equipped shops and laboratories.

BROOKLYN INSTITUTE, DEPT. OF ELECTRICITY.

The members of the department of electricity of the Brooklyn Institute held their annual meeting in the Art building on May 19, and elected officers for the ensuing year: President, James Hamblet; vice-presidents, William S. Barstow and J. P. Wintringham; secretary, Henry T. Weed. The lecture of the evening was delivered by Dr. Charles E. Emery, the recently elected president of the New York Electrical Society, and president of the institute department of engineering. Dr. Emery's subject was, "The Electrical Transmission of Energy," and the lecture was devoted to showing the economic status of the electric current in doing work at points near and remote from the source of energy.

EDUCATIONAL OPPORTUNITIES AT WORCESTER POLYTECHNIC.

In the interests of your readers, will you kindly note the fact that, by recent enactment of the State Legislature, twenty new free scholarships in the Worcester Polytechnic Institute become available to the next entering class? This makes forty free scholarships, in all, available, being one for every Senatorial district in the State, in addition to the twenty-five or thirty free scholarships to which students from Worcester County only are eligible.

T. C. MENDENHALL,
President.

MECHANICAL.

THE RAWORTH UNIVERSAL HIGH SPEED ENGINE.

THIS engine, designed by Mr. J. S. Raworth, and built by the Brush Electrical Engineering Company, of London, a general view of which is shown in Fig. 1, is essentially a tandem engine, and is built either simple, compound, triple, or quadruple expansion, according to the requirements of the load. The cylinders are placed in pairs, one above the other, and the valves, which are of the Corliss type, are placed between the cylinders. The high pressure valve is distinct from that on the low pressure side.

The high pressure presses on the under surface of the upper piston, and the expanded steam from the receiver presses on the upper surface of the low pressure cylinder. During the down stroke to the point of cut-off the receiver and high pressure cylinder are in communication with the low pressure cylinder, the two former being arranged so that their difference in steam pressure shall be very small.

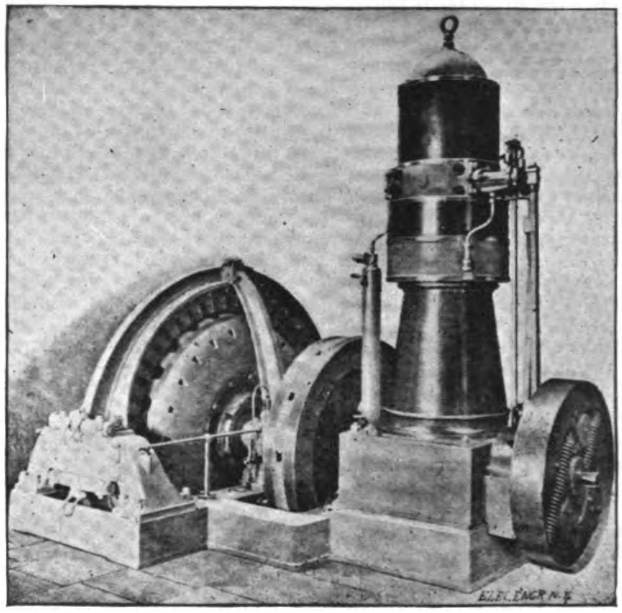


FIG. 1.—THE RAWORTH UNIVERSAL ENGINE DIRECTLY CONNECTED TO MORDEY ALTERNATOR.

The low pressure cylinder steam on the downward stroke of the piston expands until the cut-off closes, when the remainder passes into the receiver, except a small amount which is retained in the cylinder for the purpose of compression. If any water is taken into the high pressure cylinder it is discharged into the low pressure, and through holes in the latter into the lower exhaust chamber when the low pressure piston reaches the bottom of its stroke.

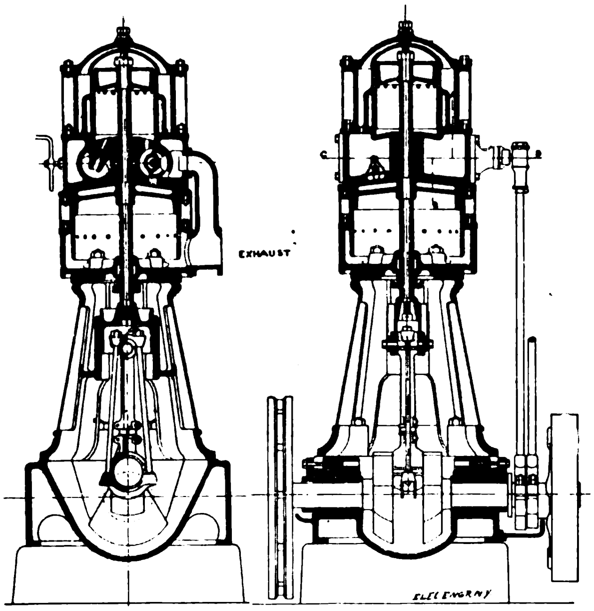
The triple and quadruple expansion engines are arranged with two cranks and two pairs of cylinders. With the former class the high pressure and intermediate cylinders are in tandem over one crank, and two low pressure cylinders are placed in tandem over the other crank.

The cross sections shown in Figs. 2 and 3 are taken at right angles and parallel to the engine shaft. These illustrations apply to the compound engine with one crank and only incidentally to the triple and quadruple patterns. The general arrangement of the parts of the engine will be understood by reference to these sections.

The high pressure eccentric is driven by a centrifugal shaft governor, which controls the cut-off from zero to ⅝ stroke, and

the low pressure eccentric is fixed solidly on the shaft so as to cut off at about ½ stroke. The lubrication is entirely automatic.

The connecting rod is made in two separate parts, one of



FIGS. 2 AND 3.—THE RAWORTH UNIVERSAL HIGH SPEED ENGINE.

which is an external frame to take the pull on the up stroke, and the other an internal strut to take the pressure of the down stroke. The governor in principle is similar to the ordinary crank shaft automatic governor, and is very simple in construction. The springs are fitted with an adjustment with

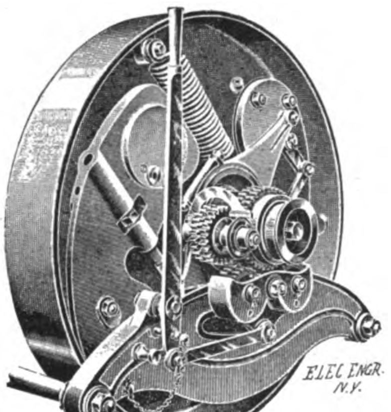


FIG. 4.—THE UNIVERSAL ENGINE GOVERNOR.

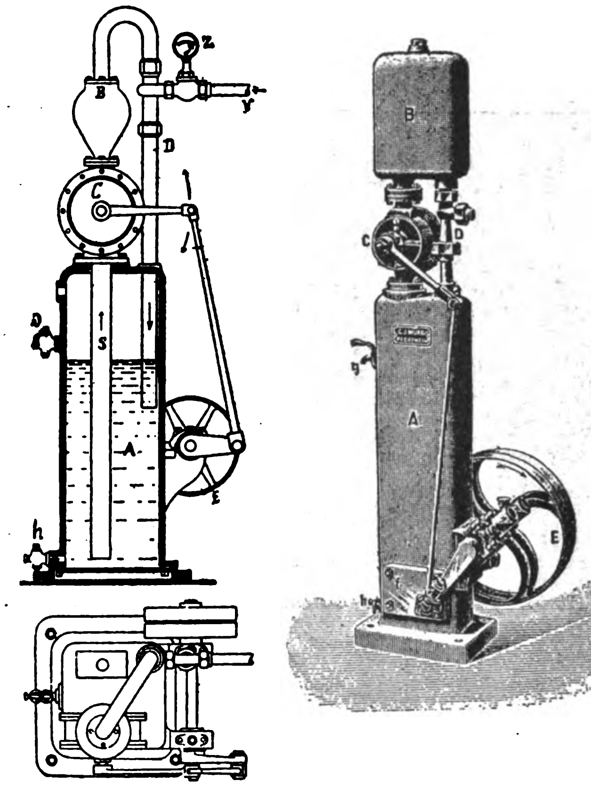
which the range of total variation in speed can be set at from one to five per cent. When the speed may be required to vary while working, the Raworth speeder gear, shown in Fig. 4, is used. This is required when the engine is used for driving alternators in parallel.

THE MURRH VACUUM PUMP.

INCANDESCENT lamp manufacturers and those engaged in vacuum tube work on a large scale, may be interested in a novel vacuum pump devised by Mr. J. Murrh, of Pforzheim, and described in "Dingler's Polytechnisches Journal." This pump is characterized by the absence of all pistons, valves and other delicate appliances usually found in ordinary air pumps. The apparatus, which is very simple, is represented in section in Fig. 1, and in elevation, with some slight modifications, in Fig. 2. It is based on the principle of the ejector and consists of a cylinder, A, three-quarters filled with water, which a rotary pump, C, draws up through the pipe, s, filling the air reservoir, B. From here the water flows out very rapidly by the pipe, D, drawing the air through the tube, v, which communicates with the vessel to be exhausted.

The mixture of water and air is returned to the cylinder, A, while the air escapes through the cock, G, the water coming



THE MURRH VACUUM PUMP.

back to the original circulation. The following table gives the dimensions and capacities of three sizes of these machines:

Floor space occupied....	0.2 sq. m.	0.3 sq. m.	0.4 sq. m.
Height	1.6 m.	1.7 m.	1.8 m.
Number rev. per minute	80	60	40
Vol. air withdra'n per hr.	4 cu. m.	8 cu. m.	12 cu. m.

The pressure of air necessary in the reservoir will not exceed 1½ atmospheres. A manometer, Z, at every instant indicates the degree of vacuum obtained in the vessel operated upon.

SOCIETY AND CLUB NOTES.

INTERNATIONAL CONGRESS OF ELECTRICAL ENGINEERS AT GENEVA.

On the occasion of the Swiss National Exhibition at Geneva, the Society of Swiss Electrical Engineers has resolved to hold, during the month of August, an International Congress of Electrical Engineers, and has now sent invitations to different foreign societies. The Congress will last four days and the following subjects have been included in the programme: (1) Magnetic units and their nomenclature; (2) Photometric units and their nomenclature; (3) Long-distance transmission of energy and its distribution by continuous and alternating currents; (4) Protection of high-pressure circuits from atmospheric discharges; (5) Disturbances caused by electric tramways. In connection with the Congress there will be excursions into the Jura and central districts of Switzerland for the purpose of inspecting various important electrical plants.

AN ELECTRIC CLUB AT WASHINGTON, D. C.

The Washington Electric Club has been organized by the election of the following officers: President, M. O. Spring; vice-president, J. K. Vose; secretary and treasurer, Arthur E. Yundt; librarian, H. P. Moore; directors, Fred Royce, Jr., Fred McIntyre, Robert D. Metzel, William Watzel, A. V. Holmes; sergeant-at-arms, William E. Dykes.

EXHIBITION NOTES—V.

THE NOWOTNY ARC LAMP EXHIBIT.

ONE of the exhibits which attracted the attention of visitors at the Electrical Exposition was that of the Nowotny Electric Company, of Cincinnati, a general view of whose

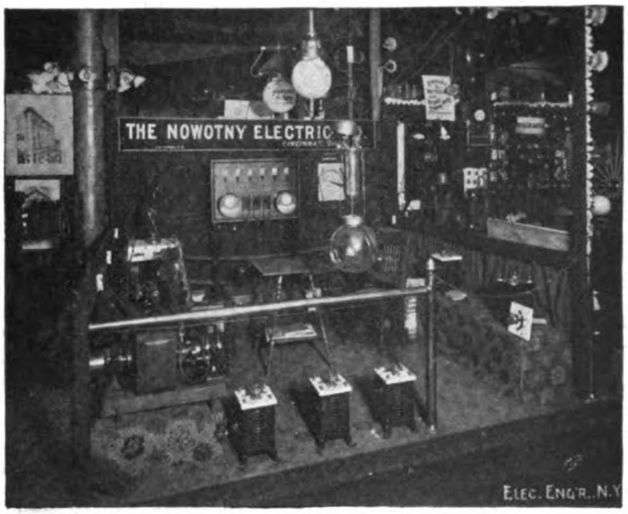


FIG. 1.—THE NOWOTNY ELECTRIC CO.'S EXHIBIT.

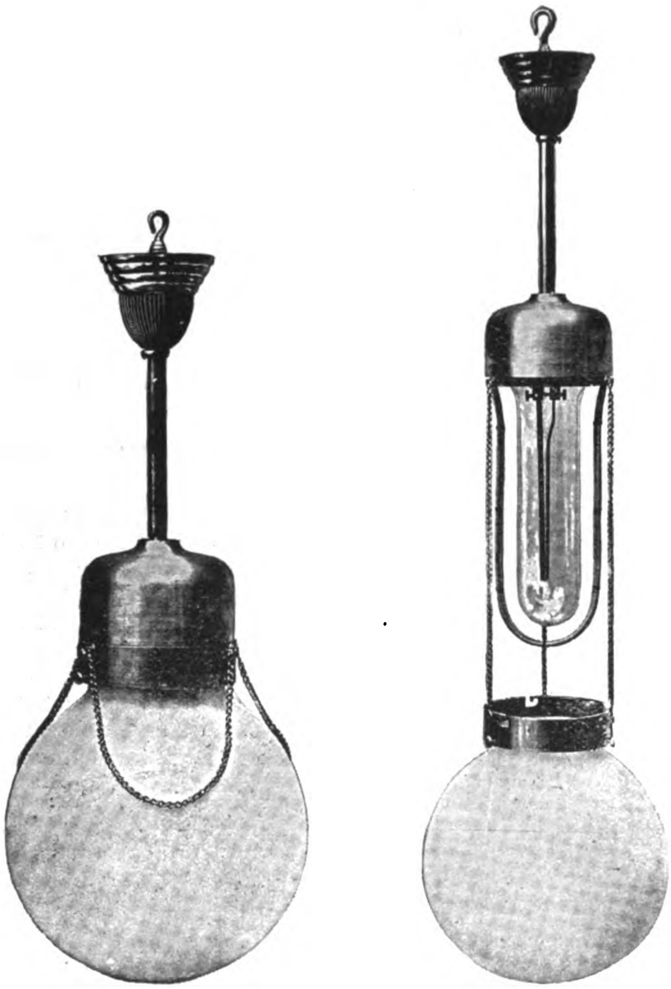
booth is shown in Fig. 1. The arc lamp which this company manufactures is shown complete in Fig. 2 in the style made



FIGS. 2 AND 3.—THE NOWOTNY ARC LAMP.

for indoor use. Figs. 3 and 4 show respectively the method of suspending the globe, and the working parts of the lamp. The carbons are placed parallel to each other throughout the entire length to be consumed by the arc, and are flat in shape, the broad sides facing each other. The arc is kept at the points of the carbons by means of a magnetic field which is generated in a coil lying in a plane parallel to the axes of both carbons, as shown in Fig. 4. The entire mechanism and the carbons are inclosed in a single glass globe which protects them from any access of fresh air, thus considerably prolonging the life of the carbons.

The only moving part in the lamp is one carbon holder, which is pivoted at the top, and allows sufficient movement, so that

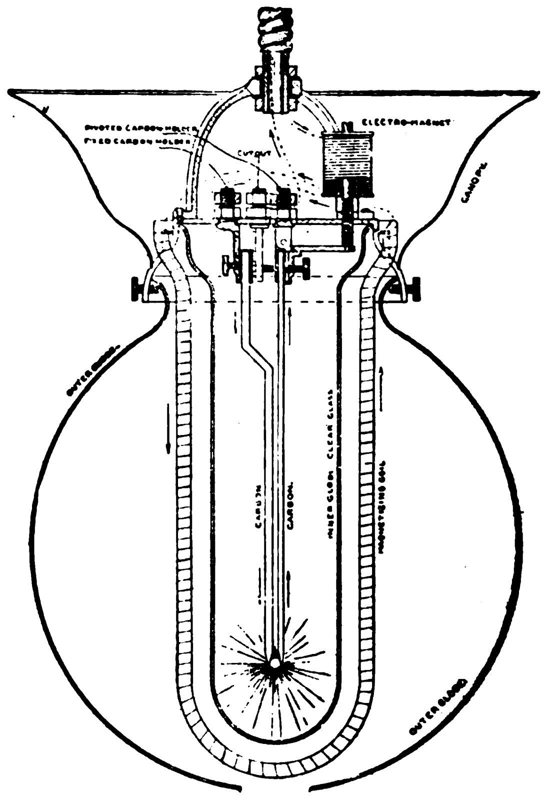


FIG. 4.—THE NOWOTNY ARC LAMP.

the points may be brought into contact at their tips and to separate sufficiently to maintain the required arc. This movement is obtained by means of a single solenoid magnet, which draws up an arm fastened to the pivoted carbon holder.

The lamp is manufactured for arc, constant potential continuous and alternating circuits. It is of a short length and occupies but little room; it is also easily trimmed and is made up in ornamental designs. An automatic cut-out is provided and an inspection of the working parts shows an entire absence of rods, sliding contacts, chimney, clockwork and springs.

THE WESTERN UNION'S RECORD IN SENDING THE DEPEW-ADAMS MESSAGES.

WE are indebted to Mr. C. A. Tinker, of the Western Union Telegraph Company, for the accompanying data in regard to the work done on the night of May 16, in sending the Depew and Adams messages around South America and across to Europe and back.

Preparatory to transmission, the circuit was made up from the exposition building to the following points, at which automatic repeaters were introduced, viz., Pittsburg, Pa.; Chicago, Ill.; Omaha, Neb.; Cheyenne, Wyo.; Ogden, Utah; Reno, Nev.; San Francisco, Cal.; Los Angeles, Cal.; Flagstaff, Ariz.; Pueblo, Colo.; Kansas City, Mo.; Chicago, Ill.; St. Louis, Mo.; Little Rock, Ark., to Galveston, Texas, a distance of 7,397 miles of wire, fourteen sets of repeaters. At the exposition building, the gold key used by President Cleveland in opening the World's Fair at Chicago in 1893 was placed in circuit.

The messages were received for dispatch by Mr. C. A. Tinker at the exposition and instantly put upon the wire in direct communication with Galveston, where they were received by Colonel L. C. Baker, superintendent, the transmission occupying six minutes, by the official time-keeper's (Mr. Abbott) record. From Galveston they were transmitted to Buenos Ayres,

via Mexican Telegraph Company and Central South American Telegraph Company (including land lines across the continent of South America, and over the Andes from Valparaiso to Buenos Ayres), 6,272 miles; via River Plate Telegraph Company, Buenos Ayres to Montevideo, 114 miles; via Western and Brazilian Telegraph lines, Montevideo to Pernambuco, 2,364 miles; via Brazilian submarine cables, Pernambuco to Lisbon, 3,663 miles; via Eastern Telegraph Company, Lisbon to Penzance, 899 miles; via Western Union Telegraph Company's Atlantic cables, Penzance to Canso, 2,620 miles. On their return the messages were received over the cable wire from Canso, N. S., 1,187 miles (repeaters at St. John, N. B., and Bangor, Me.), and copied upon a typewriter by Operator George W. Dickson, and delivered to Mr. Depew. The two messages contained sixty-eight words, and were transmitted from the exposition building, New York, over a total distance by land lines and cables, of 24,516 miles, and received back at the exposition building in twenty-one and one-half minutes.

NILES TOOL WORKS CO.'S EXHIBIT.

The Niles Tool Works Co., of Hamilton, O., had a prominent place on the main floor and were the only machine tool builders to make an exhibition of machine tools driven by electric motors. The No. 1½ radial drilling machine attracted much attention, as it was driven direct by a three horse-power Card motor, no belts being used, and also on account of the universal manner and ease with which it could be operated.

Another machine of no less importance from a mechanical standpoint was the thirty-seven-inch boring and turning mill.

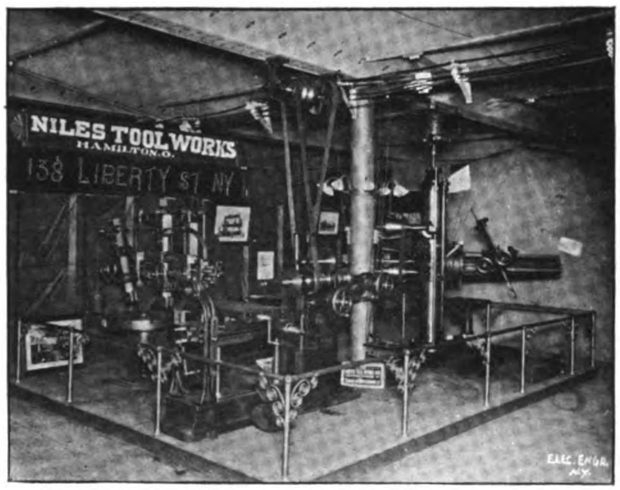

EXHIBIT OF THE NILES TOOL WORKS.

This machine was driven direct by a three horse-power Card motor, which occupied the place on the driving shaft usually taken by the cone pulley when the machine is driven by belt. The rheostat or controller of this machine has seven changes and of course the back gear doubles this or makes fourteen changes in all.

The other machine on exhibition was their No. 1 horizontal boring and drilling machine. This machine was belted from a countershaft and the countershaft was driven by a 2½ horse-power Card motor, bolted to the floor. All the above machines were run at the same speeds generally used in modern machine shop practice, and when in motion one could see how smooth was the working of the parts.

Card motors, built by the Card Electric Motor and Dynamo Company, of Cincinnati, O., were used by the Niles Company in their installation. Mr. Becker, the representative of the Niles Company, informs us that the Card motors have given excellent satisfaction wherever placed by his company on their machinery.

The Niles Tool Works were among the first to adopt electric motors direct on machine tools, and the success of their venture proves that direct driven machine tools is what the machine tool users want.

Mr. Becker has shipped the entire above exhibit to Boston, Mass., where the Niles Company intend to place it in their store and have the exhibition of these tools permanent. The Niles Company report some sales and many inquiries during the show, and are well pleased with the success of the exhibition generally.

A. K. WARREN & CO.'S EXHIBIT.

THE accompanying illustration shows the booth of A. K. Warren & Co., at the Electrical Exposition. Their exhibit was an eminently practical one, as the work of rewinding and repairing electrical machinery was actually carried on by workmen. The exhibit also included special tools which may

A. K. WARREN & CO.'S EXHIBIT.

be adjusted to any dynamo for the purpose of turning off commutators without the removal of the armatures. Besides these there were also shown various styles of brushes and brush holders, and numerous other parts which are called for in the repairing and maintenance of electrical machinery which is carried on by this company.

THE BRADFORD BELTING CO.'S EXHIBIT.

WE illustrate herewith the exhibit of the Bradford Belting Company, of Cincinnati, O., which contained a complete line of Monarch belting and Monarch paints. The Monarch paint proved a noticeable attraction, as samples of wood and

THE BRADFORD BELTING CO.'S EXHIBIT.

iron covered with it were freely exposed to the action of a torch without producing any deleterious effects.

This insulating paint is largely used for insulating armatures, fields and other electrical apparatus, and the tests to which it was subjected during the exposition left a favorable impression of its merits upon all who witnessed them.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S ELECTRICAL PATENTS ISSUED MAY 26, 1896.

Conductors, Conduits, and Insulators:—

CABLE GRIP. P. Wunderle, Providence, R. I., 560,828. Filed March 24, 1896.
The weight of the cable keeps clip in place.

Distribution:—

ELECTRICAL DISTRIBUTING SYSTEM. R. R. Bowker, Brooklyn, N. Y., 560,772. Filed Feb. 27, 1896.
For description see page 620, this issue.

SYSTEM OF ELECTRIC DISTRIBUTION. P. O. Keilholtz, Baltimore, Md., 561,002. Filed Feb. 29, 1896.
Consists in reducing its field strength and load in accordance with the current applied to the armature.

Dynamos and Motors:—

ELECTROMAGNETIC MOTOR. F. M. Schmidt, Brooklyn, N. Y., 560,652. Filed Jan. 18, 1896.

ALTERNATING CURRENT GENERATOR. W. S. Moody, Lynn, Mass., 560,735. Filed Jan. 17, 1896.
Method of compounding alternating dynamo electric machines for change of potential under change of load.

COMMUTATOR BRUSH. W. H. Morgan, Alliance, O., 560,737. Filed Feb. 20, 1895.
Composed of a series of independently yielding sections having curved non-coincident contact edges.

Electro-Metallurgy:—

ELECTROLYTICAL APPARATUS. W. S. Rawson, London, England, 560,931. Filed March 21, 1895.
Apparatus for effecting electrolytical deposit of metal upon such articles as can be rolled over and over in a revolving barrel, so arranged that these articles constitute the cathodes as they roll on the periphery of the barrel.

Lamps and Appurtenances:—

INCANDESCENT LAMP SOCKET. H. C. Wirt, Schenectady, N. Y., 560,667. Filed Feb. 17, 1896.
The base is formed of molded insulating material.

ELECTRIC ARC LAMP. T. E. Adams, Cleveland, O., 560,671. Filed Jan. 4, 1896.
Comprises an inner arm inclosing globe having its bottom completely and permanently closed and its top normally closed.

ELECTRIC ARC LAMP. J. H. J. Haines, New York, and A. B. Fernald, Jersey City, N. J., 560,792. Filed Jan. 7, 1896.
Embodies a "ball-clutch" feed mechanism.

COMBINED GAS AND ELECTRIC LIGHT FIXTURE. L. Stieringer, New York, 11,544. Filed March 4, 1894. Reissued.
See page 607, E. E., June 3.

Miscellaneous:—

APPARATUS FOR PRODUCING MUSICAL SOUNDS BY ELECTRICITY. G. Breed, Philadelphia, Pa., 560,679. Filed Nov. 20, 1894.
A series of musical strings, in combination with a series of electromagnets arranged in parallel and connected with a source of electric energy, and a system of two-way switches controlling the current to the electromagnets.

FEED-WATER PURIFIER. M. S. Cabell, Quincy, Ill., 560,685. Filed Dec. 26, 1894.
Electropositive and electronegative plates having perforations for the passage of the feed-water and means for spraying the water upon the same.

ELECTRIC VALVE. C. L. Fortier, Chicago, Ill., 560,703. Filed Oct. 10, 1892.
Means for preventing sticking of the armature to the cores of the magnet.

AUTOMATIC HEAT REGULATING DEVICE. J. V. Stout, Easton, Pa., 560,763. Filed June 6, 1895.
Details of construction.

STATIC ELECTRICAL MACHINE. C. M. Hollopeter, Fostoria, O., 560,852. Filed July 10, 1895.
A rectangular frame, consisting of opposite insulated pairs of frame conductor rods, the stationary and revolving generator plates mounted within the frame, and swinging adjustable prime conductors pivotally connected, respectively, with the opposite pairs of frame rods.

THERMOMETRIC CIRCUIT CLOSER OR ALARM. R. Pearson, London, England, 560,921. Filed Sept. 3, 1895.
A mercury column makes contact between platinum contacts.

LIGHTNING ARRESTER. W. Cooper, Schenectady, N. Y., 561,073. Filed Sept. 23, 1895.
An air-tight box having terminals with a gap between them, and a weak cover that is adapted to be blown away.

ELECTRO-THERAPEUTIC APPARATUS FOR TREATING DEAFNESS. S. J. Collier, Chicago, Ill., 561,046. Filed Oct. 22, 1895.
Designed to supply a mechanical massage to the ear drum, muscles and small bones of the ear, and at the same time to stimulate the nerves and muscles with a secondary current of electricity.

Railways and Appliances:—

CONTROLLER FOR ELECTRIC CARS. E. A. Sperry, Cleveland, O., 560,658. Filed March 20, 1896.
A single reversing switch for reversing the direction in which the car shall travel and also for reversing the relation between the armature and field coils when the brake is to be used.

ELECTRIC BRAKE. W. B. Potter, Schenectady, N. Y., 560,751. Filed March 13, 1896.
The combination of a controlling switch, a reversing switch, and a braking switch provided with two sets of contacts corresponding to the forward and backward running positions of the reversing switch, and an interlock between the reversing switch controller and braking switch; the interlock arranged to permit the operation of the braking switch in one direction when the reversing switch is set forward, and in the other direction when the reversing switch is set back.

ELECTRIC RAILWAY. H. Brandenburg, Chicago, Ill., 560,678. Filed March 11, 1895.
A slotted tubular conductor, a trolley having a beaded plate and a sleeve carrying a multiplicity of contacts mounted on said bead.

ELECTRIC RAILWAY. E. H. Johnson, New York, and R. Lundell, Brooklyn, N. Y., 560,721. Filed Oct. 15, 1895.
Consists in conveying the leaking currents around the switching mechanism and thereby causing said switching mechanism to assume normal position.

CONDUIT ELECTRIC RAILWAY. W. Lobach, Chicago, Ill., 560,807. Filed April 23, 1894.
A conduit containing a liquid insulator heavier than water, in which the conductor is laid.

CURRENT COLLECTOR FOR ELECTRIC RAILWAYS. A. N. Connett, Washington, D. C., 560,841. Filed Jan. 17, 1896.
A traveling contact comprising a hanger, oppositely disposed contact shoes, an interposed toggle, and a spring connection between the toggle and hanger.

CURRENT COLLECTOR FOR ELECTRIC RAILWAYS. A. N. Connett, Washington, D. C., and J. S. Detrick, Baltimore, Md., 560,894. Filed Jan. 17, 1896.
Similar to above.

ELECTRIC RAILWAY. W. H. Jordan, Brooklyn, N. Y., 560,903. Filed Jan. 17, 1896.
System of signaling.

ELEVATED ELECTRIC RAILWAY. J. H. McGurty, Jersey City, N. J., 560,917. Filed June 13, 1895.
Comprises a switch upon the car and trips at proper intervals for engaging with the switch to make and break the circuit automatically.

ELECTRIO RAILWAY SYSTEM. N. J. Halpine, United States Navy, 560,988. Filed Feb. 1, 1893.
A sectional conduit system in which the sections are shorter than the car; the conductor being protected by the car while the car is receiving current.

ELECTRIC LOCOMOTIVE. J. C. Henry, Denver, Colo., 11,542. Filed Nov. 21, 1893. Reissued.
In combination with the wheels and axles of a car truck, a frame supported on said axles, a motor supported rigidly on said frame by its fields and having a bearing adapted to receive the weight of the car body.

ELECTRIC LOCOMOTIVE. J. C. Henry, Denver, Colo., 11,543. Filed Nov. 21, 1893. Reissued.
Speed reducing gear connecting the armature shaft of motor with the axles and comprising an internal gear which has bearing on one of the bars of the truck frame.

Switches, Cut-Outs, Etc.:—

CONTROLLABLE SWITCH BOX. J. Van Vleck, New York, 560,766. Filed Jan. 3, 1896.
For description see page 620, this issue.

AUTOMATIC FUSE. H. C. Reagan, Jr., Philadelphia, Pa., 560,819. Filed Sept. 6, 1895.
One fuse is put in circuit after the other.

ELECTRIC CUT-OUT. J. C. Reynolds, New York, 560,821. Filed Jan. 25, 1896.
The wires are coupled to studs of insulating material and are pressed into contact by a cap of inclosing cover, also of insulating material.

AUTOMATIC DEVICE FOR REMOVING RESISTANCE IN STARTING ELECTRIC MOTORS, ETC. G. H. Whittingham, Baltimore, Md., 11,545. Filed April 24, 1894. Reissued.
A pawl and ratchet operated by the motor armature and adapted to impart to the contact device a limited movement in the direction which reduces the resistance of the armature circuit.

Telephones:—

BUSY SIGNAL FOR TELEPHONE LINES. C. E. Scribner, Chicago, Ill., 560,757. Filed Aug. 17, 1895.
A switch lever of a telephone set, an indicator adapted to be set by the movement of the lever, a detent controlling the movement of the indicator, and an electromagnet acting upon the detent.

TELEPHONE CIRCUIT. J. S. Stone, Boston, Mass., 560,761. Filed March 13, 1896.
The combination, with a telephone circuit, of a generator and a relay in a permanent bridge between the circuit conductors, the generator being interposed between the coils of the relay, and a local circuit, including a battery, a line lamp signal controlled by the relay, and means for shunting the signal when connection is made with the line.

TELEPHONE CIRCUIT AND APPARATUS. J. S. Stone, Boston, Mass., 560,762. Filed April 2, 1896.
A telephone system of two telephone circuits, an electromagnetic device interposed in the circuit and placed in such relation to the transmitter and receiver and to the terminals of the other circuit as to constitute a repeating induction coil between the instruments.

TELEPHONE EXCHANGE SYSTEM. W. W. Dean, St. Louis, Mo., 560,845. Filed April 3, 1896.
Means for closing the battery circuit over the two limbs of each of the telephone lines.

MULTIPLE TELEPHONY. F. A. Pickernell, Newark, N. J., and F. S. Perrin, New York, 560,861. Filed March 21, 1896.
Has for its object the establishment of a practical working balance in superimposed circuits.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JUNE 2, 1896.

Alarms and Signals:—

SIGNAL BOX. J. J. Ruddick, Newton, Mass., 561,525. Filed Sept. 20, 1895.
Consists of an escape-wheel, signal-pins on its side, arranged in groups and forming lateral extensions of the teeth, and a circuit-breaker, the movable member of which is operated by the signal-pins.

SIGNAL BOX. J. J. Ruddick, Newton, Mass., 561,526. Filed Oct. 9, 1895.
Governing devices for the escape-wheel which are constructed to retard its action.

Primary Batteries:—

COMPOSITION FOR EXCITING FLUIDS FOR ELECTRICAL BATTERIES. F. G. Curtis, Philadelphia, Pa., 561,204. Filed Feb. 13 1893.
Consists of a solution of sulphate of aluminum, acetate of lead, hyposulphite of soda and sulphuric acid.

POLE PIECE FOR ELECTRICAL BATTERIES. F. G. Curtis, Philadelphia, Pa., 561,205. Filed Feb. 20, 1893.
A carbon plate having electrically deposited thereon an alloy of copper and tin.

Conductors, Conduits, and Insulators:—

WIRE CONNECTOR. A. Gartner, Newark, N. J., 561,388. Filed April 17, 1896.
Consists of a metallic block provided with a central opening, and with two oppositely-arranged openings adapted to receive the wires to be jointed and their bent-over portions, respectively.

WIRE CONNECTOR. D. M. Robertson, Kearney, N. J., 561,438. Filed April 17, 1896.
Consists of two adjoining connecting-channels circular in cross-section.

Dynamos and Motors:—

ALTERNATING ELECTRIC MOTOR. J. A. G. Trudeau, Ottawa, Canada, 651,144. Filed July 18, 1894.
The armature coils and field coils are both connected to a source of electric supply, but in shunt relation to each other.

DYNAMO ELECTRIC MACHINE. A. I. Gravier, Paris, France, 561,390. Filed April 7, 1894.
Consists of an armature having a core, the windings on the same being arranged in sections which are mechanically and electrically independent of each other.

Lamps and Appurtenances:—

ELECTRIC LAMP HANGER. J. Schmidt, New York, 561,443. Filed Feb. 11, 1896.
A rotary spindle and means for rotating the same.

Measurement:—

ELECTRIC METER. A. G. Waterhouse, Hartford, Conn., 561,183. Filed May 27, 1895.
Consists of a time mechanism connected to a working circuit and adapted to run while a current is passing through the circuit.

Miscellaneous:—

TARGET APPARATUS. J. L. McCullough, Brooklyn, N. Y., 561,124. Filed March 13, 1896.
Means for showing whether aim is correct without the use of missiles.

ELECTRIC HEATER. H. A. Thomas, Niagara Falls, N. Y., 561,294. Filed Feb. 6, 1895.
Adapted for car use.

INDICATOR FOR THE SPEED OF REVOLUTION OF PROPELLERS. M. Pfatischer, Philadelphia, Pa., 561,430. Filed Aug. 12, 1895.
The current strength of a magneto-generator driven by the engine shaft indicates the speed.

TELLTALE FOR STEERING GEAR OF SHIPS. M. Pfatischer, Philadelphia, 561,431. Filed Aug. 12, 1895.
Mechanical connections between steering gear and a movable contact arranged to make a connection with a series of fixed contacts.

Railways and Appliances:—

TROLLEY SWITCH. M. Rangey and P. Plants, Schenectady, N. Y., 561,128. Filed Jan. 17, 1896.
Means for mounting it upon the wires without soldering.

TROLLEY STAND. F. N. Kelsey, New Haven, Conn., 561,168. Filed March 28, 1895.
Details of construction.

ELECTRIC RAILWAY. H. Brandenburg, Chicago, Ill., 561,307. Filed May 22, 1895.
Provides a conduit wherein the electric features may be auxiliary to a cable system.

MAGNETIC MEDICAL APPARATUS. A. B. Slater and N. A. Renstrom, Omaha, Neb., 561,448. Filed Oct. 9, 1894.
A support for a body, and electromagnets distributed beneath the surface of the support so as to create a magnetic field therein.

Switches, Cut-Outs etc:—

DOOR LOCK SWITCH FOR ELECTRIC LIGHTS. W. E. Goucher, Jamestown, N. Y., 561,107. Filed Jan. 2, 1896.
Locking the door breaks the circuit.

ELECTRIC SWITCH. F. Land, Syracuse, N. Y., 561,116. Filed June 19, 1895.
Adapted for use in an arc lamp.

FUSIBLE CUT-OUT. L. W. Downes, Providence, R. I., 561,159. Filed April 17, 1895.
A fuse-wire combined with a sheath of incombustible, insulating material, inclosing the fuse-wire and confining a body of air.

ELECTRIC SWITCH. H. Ross, Providence, R. I., 561,284. Filed Feb. 17, 1896.
Details of construction.

Telegraphs:—

AUTOMATIC TELEGRAPH. S. P. Freir, Hasbrouck, N. J., 561,547. Filed Aug. 9, 1893.
The combination of main-line transmitting apparatus by which the positive or negative pole of a battery or batteries may be directed to line, and variable-pressure main-line contact devices, whereby the touch of the fingers in the manual transmission of messages of such character may be reproduced.

Telephones:—

TELEPHONE EXCHANGE SYSTEM. K. B. Miller, Wilkinsburg, Pa., 561,335. Filed Feb. 18, 1896.
The subscribers' lines terminate in spring-jacks arranged in divided boards.

AUTOMATIC TELEPHONE CALL. G. Q. Dean and J. Dean, Jr., New York, 561,377. Filed Aug. 3, 1895.
A movable contact maker combined with a movable core, a vitalizer for the core, and a detent actuated by said core.

ATTACHMENT FOR TELEPHONES. J. H. Miller, Washington, D. C., 561,416. Filed March 12, 1896.
An attachment for preventing the turning of the bell-crank when telephone is in connection with another.

TELEPHONE SYSTEM. P. Minnis, Mobile, Ala., 561,417. Filed Feb. 17, 1896.
A series of subscribers' circuits connected to a return wire, a series of talking sets directly in the line-circuits and talking batteries in loop cords at the central station arranged so that the polarity of the several batteries in the return wire shall be the same.

TELEPHONE EXCHANGE SYSTEM. P. Minnis, Mobile, Ala., 561,418. Filed Feb. 17, 1896.
Similar to above.

SWITCHBOARD FOR TELEPHONE SYSTEMS. P. Minnis, Mobile, Ala., 561,419. Filed Feb. 17, 1896.
Relates to visual call-signals.

LINE-JACK FOR TELEPHONIC SWITCHBOARDS. P. Minnis, Mobile, Ala., 561,420. Filed Feb. 17, 1896.
So constructed that two separate wires entering it may be connected by a slight movement of the operator's finger.

TELEPHONE CALL BOX. P. Minnis, Mobile, Ala., 561,421. Filed Feb. 17, 1896.
Details of construction.

TELEPHONE CALL SIGNAL FOR CENTRAL STATIONS. P. Minnis, Mobile, Ala., 561,422. Filed Feb. 17, 1896.
Employs small incandescent lamps.

TELEPHONE. P. Minnis, Mobile, Ala., 561,423. Filed Feb. 17, 1896.
Arrangement whereby the receiver and transmitter may be mounted upon a single handle.

TELEPHONE SWITCH PLUG. P. Minnis, Mobile, Ala., 561,424. Filed Feb. 17, 1896.
A plug having a cap, whereby two wires may be connected by pushing said cap.

PARTY-LINE TELEPHONE APPARATUS. W. W. Dean, St. Louis, Mo., 561,498. Filed March 28, 1896.
Means for communication between several subscribers without calling the central station.

LEGAL NOTES.

NIAGARA WATER POWER UTILIZATION.

On Thursday, May 28, just before the close of the thirty-day period following the end of the Legislature's session, Governor Morton signed the bill confirming and ratifying the power rights of the Niagara Falls Hydraulic Power and Canal Company, of which W. C. Johnson, Amer. Soc. Civ. Eng. is chief engineer. This company is the oldest power concern at the Falls, and now for the first time it has a legal and recognized right to divert water from the Niagara River for power purposes, the bill containing the following important declaration:

"Section 1. The right of the Niagara Falls Hydraulic Power and Manufacturing Company to take, draw, use, and lease and sell to others to use the waters of Niagara River for domestic, municipal, manufacturing, fire, and sanitary purposes and to develop power therefrom for its own use and to lease and sell to others to use for manufacturing, heating, lighting, and other business purposes, is hereby recognized, declared, and confirmed, and the exercise thereof by said company, its successors, and assigns, to take and to draw water from Niagara River for use and disposal to others to use for the purpose above specified, and for the development of power for use and for disposal to others to use, for purposes above mentioned, is hereby limited and restricted to such quantity of water as may be drawn by means of the hydraulic canal of said company when enlarged throughout its entire length to a width of 100 feet and to adopt a slope sufficient to carry at all times a maximum uniform depth of fourteen feet of water, provided that exercise by said company of the rights hereby declared and confirmed shall not impair the practical navigation of Niagara River.

NEWS AND NOTES.

LORD KELVIN'S JUBILEE.

The following is to be the programme of the jubilee celebrations of Lord Kelvin's professoriate at Glasgow. On the evening of Monday, Jun 15, at 8:30 o'clock, the University will give a conversazione, when there will be an exhibit of Lord Kelvin's inventions. On Tuesday, June 16, addresses will be presented to Lord Kelvin by delegates from home and foreign University bodies, from several of the learned societies of which he is a member, from student delegates from other universities, and from the students and graduates of the University of Glasgow. It is expected that the honorary degree of LL. D. will be conferred on the same day on several of the distinguished foreign visitors. On Tuesday evening, June 16, the city will give a banquet to Lord Kelvin, to which the visitors who have come to do him honor have been invited. On Wednesday, June 17, the senate of the University will invite the visitors of the University staff to sail down the Clyde. The students of the University also invite the student delegates from other universities to a similar trip. Representative scientific men—about fifty in number—from America and the British colonies, and from all the European countries, and about 150 from the United Kingdom have signified their intention to be present.

THE "ELECTRICAL ENGINEER'S" COLUMBIAN EXPOSITION AWARD.

The Electrical Engineer has just received a diploma and bronze medal for the 1837 model of Davenport's electric railway exhibited by it at Chicago in 1893.

Trade Notes and Novelties

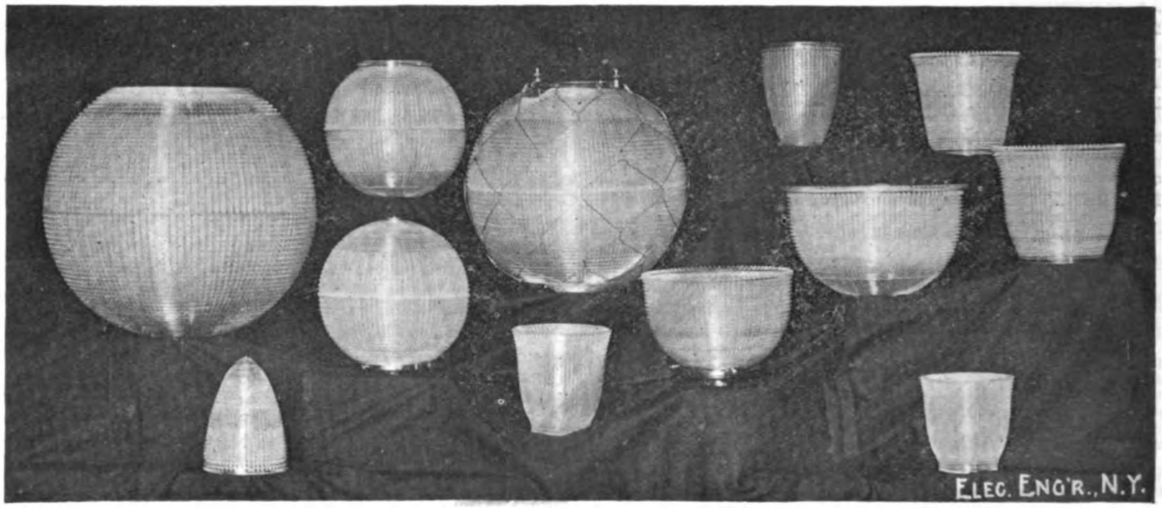
AND MECHANICAL DEPARTMENT.

HOLOPHANES.

THE name "holophanes" has been adopted by the George A. Macbeth Company, of Pittsburg, Pa., for a new line of shades which they are manufacturing and which have some special features that will be seen in the accompanying illustration.

These holophanes are made of plain glass, the inner surface of which is pressed into horizontal groovings of well defined curvature, and the exterior is formed under heavy pressure into prisms or rings, constructed so as to both reflect and refract the light. By this means the source of light is not visible, but is diffused evenly from the entire surface of the shade.

This even, luminous surface is not produced by any opaqueness or roughness of the glass which would absorb considerable of the light emitted by the lamp, but is due entirely to the arrangement of the reflecting and refracting surfaces and prisms of the shades. There is an entire absence of alternate light and dark streaks upon the shades, and no shadow is produced directly underneath them. The holophanes are manufactured in various shapes and sizes, so as to direct the light either horizontally or downward, or both, as may be required, and are made for use with both arc and incandescent lamps.



HOLOPHANE GLOBES FOR ARC AND INCANDESCENT LAMPS.

NIAGARA FALLS POWER CO.

The annual meeting of the Niagara Falls Power Company was held June 1, and the old directors and officers were reelected. The principal officers are: President, Dr. Coleman Sellers, of New York; vice-president, Benjamin Flagler, of Niagara Falls; second vice-president, Charles Sweet, of Buffalo.

Contracts were executed with the Westinghouse Electric Company for seven more 5,000 horse-power dynamos and the E. D. Smith Company, of Chicago, for the wheel pit and power house extension. The work will involve about $3,000,000. The extension is to furnish power for Buffalo, beginning June, 1897, under the terms of the contract with the city, already published in our columns.

CARBORUNDUM.

THE Carborundum Company, of Niagara Falls, N. Y., have just published a very complete catalogue describing their product which has been found to be next to the diamond in the scale of hardness. Carborundum is the invention of Mr. E. G. Acheson, president of the Carborundum Company, who for a long time was occupied with experiments to produce an abrasive substance for industrial purposes which would excel emery and corundum in hardness. As the diamond, which is a carbon crystal, is the hardest substance known, the idea was conceived of heating carbon and clay together, so that when the latter was fused the carbon would dissolve in the silicate of alumina of the clay, and on cooling carbon crystals would be formed.

A company was formed in Monongahela, Pa., in 1891, to carry out this operation experimentally, and the success which was achieved in producing a very hard abrasive led to the foundation of a plant at Niagara Falls, where the current necessary for the manufacture of carborundum was available to any amount.

About 1,000 horse-power in current is used by this company in the manufacture of carborundum, and their present output is about two tons per day.

Among the properties of this substance may be mentioned its infusibility and insolubility. It separates into carbon and silicon when raised above the temperature at which it is manufactured, but with no signs of fusion, and even hydrofluoric acid has no effect upon it. Its specific gravity is 3.23, and its prevailing colors are green, blue and black.

Carborundum is sold for industrial purposes in the shape of crystals and powders of various degrees of fineness, and also in numerous forms of grinding tools, as well as on cloth. For grinding and polishing purposes it has been found of unusual value, and its merits are also attested by awards of medals from the Franklin Institute and the Columbian Exposition.

BALL ELECTRIC LIGHTING PLANT.

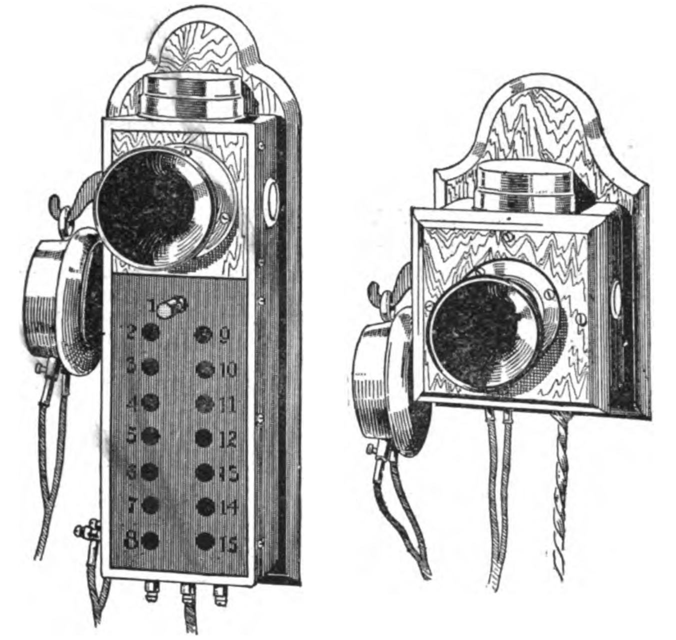
The Ball Electric Light Company, who had a very neat exhibit at the Electrical Exposition, are able also to give out a good list of recent sales, backed up by some very handsome testimonials. The apparatus on view at the show has already been disposed of. The company's recent sales are: West Warren Cotton Manufacturing Company, Warren, Mass, 200 lights; Androscoggin (Me.) Mills, 100 lights; Dunn Worsted Mills, Woonsocket, R. I., 100 lights; Berkshire Cotton Manufacturing Company, Adams, Mass., 250 lights; Lake City (Fla.) Water and Light Company, 100 lights; Heather & Co., New York City, 20 lights; Hilton, Dodge Lumber Company, 16 lights; Ellenville, N. Y., 70 lights, making a total of 786 arcs lately sold.

L. A. CHASE & CO.

L. A. CHASE & COMPANY (Incorporated), of 161 Forthill square, Boston, Mass., have issued a catalogue displaying a somewhat novel feature. They convey to the public a convincing idea of the extensive facilities with which their electrical manufacturing and repair factory is provided, not so much by verbal description as by a series of excellent photographic reproductions of the equipment of their several departments. Besides the shops devoted to dynamo and motor work, armature winding, etc., the testing department is fully illustrated. Its equipment is thoroughly up to date, including the most modern instruments for testing in all classes of electrical work, such as wattmeter tests, voltmeter calibration, high and low resistance measurements, lamp testing, and various other essential tests, so often out of reach of electrical stations.

THE SIMPLEX INTERIOR TELEPHONES.

The Simplex Interior Telephone Company, 611 Johnstone Building, Cincinnati, are making a line of residence and intercommunicating instruments, two of which we illustrate below. Fig. 1 shows an instrument for intercommunication between various points within large stores, office buildings, factories, etc., wherever quick local communication is required. In this system any one station may connect direct with any other station and no central station is required. These instruments are of small size and they have a maximum capacity of thirty stations. Fig. 2 shows an hotel instrument



FIGS. 1 AND 2.—THE SIMPLEX INTERIOR TELEPHONES.

of novel design, which does not require a battery at each instrument. It can be readily attached to existing push button wires, and in connection with a switching device for annunciators makes a complete system for communication from different points to one central point, as from the various rooms of a hotel to the office. If desired this instrument may be applied to a part of the rooms only, without interfering with the present service of the rest. The company are doing a nice business in these telephones, which are giving general satisfaction.

AMERICAN GOODS FOR ENGLAND.

Mr. F. T. Eggers, managing director of the Electrical Company, Limited, of London, has been in this country arranging for the opening of an American department for the sale of electrical apparatus and supplies in London.

The Electrical Company, Limited, have an extensive office and warehouse at 122 and 124 Charing Cross Road, London, and are a branch of the great Allgemeine Elektricitäts Gesellschaft, of Berlin. To keep in touch with American manufacturers, Mr. Eggers has arranged with the Chapin-Douglas Electric Company, 136 Liberty street, New York, to do the buying, and to this firm should be addressed price lists and proposals for the exclusive sale in the United Kingdom of apparatus and specialties. Attention will also be given to new inventions either for the financing of patents for England or the control in selling the goods themselves.

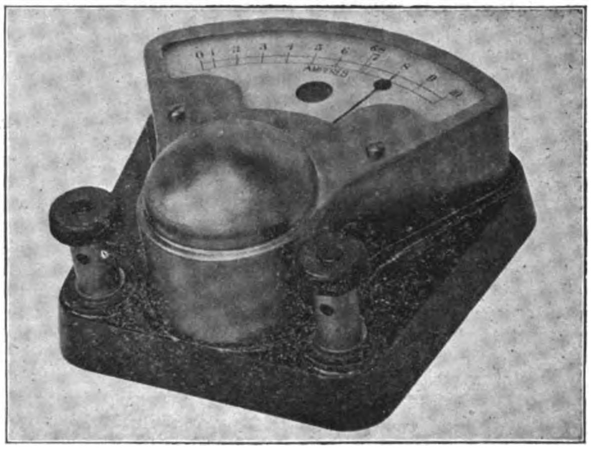
TRANSLUCENT FABRIC CO.

The special fabric made by the Translucent Fabric Company, Quincy, Mass., is now taking an important place as a substitute for glass in mills, foundries, gunpowder mills, machine shops, train sheds, and all places where the breakage of glass constitutes an element of danger, annoyance and expense. The introduction of iron and steel in the construction of buildings has given quite an impetus to the demand for the new material, which consists of wire cloth, 12 meshes to the inch, covered and filled in with a semi-transparent, impervious substance. This fabric transmits a large amount of light, and is strong, flexible, weatherproof, durable, and practically unbreakable. It has the further important advantage of being virtually fireproof. Its cost is about the same as that of heavy skylight glass.

THOMSON ARC CIRCUIT AMMETER.

The standard instruments which the General Electric Company have lately placed upon the market include the Thomson arc circuit ammeter. This is an instrument intended for switchboard purposes and is mounted upon a black enameled metal base, with the cover, binding posts and screws of bright nickel. It measures over all 8 x 8 inches.

The qualities claimed for this instrument are its high degree of accuracy, its perfect and permanent reliability for service, together with an absolute dead-beat movement of the pointer. The scale is long and may be clearly read from a distance. One ammeter may be used for either half or full arc



THOMSON ARC CIRCUIT AMMETER.

circuit, the divisions being wide and the calibration marked for both services. Permanency of calibration is obtained by the elimination from the instrument of any parts liable to change. Each ammeter is provided with a self-contained and conspicuous polarity indicator, consisting of two signals, the white showing under normal conditions, the red or reversal, the latter remaining in sight until the current has once more passed through the instrument in the proper direction. The ammeter may be used for front or back connections, connection posts and studs being furnished as conditions require. Several of these instruments were shown at the Electrical Exposition in New York during the convention of the National Electric Light Association.

NATIONAL ELECTRIC HEADLIGHTS.

The National Electric Headlight Company, of Indianapolis, Ind., have issued a booklet of instructions to engineers for the care and handling of their electric headlights for locomotives.

The apparatus used for this headlight consists of a complete engine and dynamo plant of miniature dimensions, which is placed on the locomotive boiler between the smokestack and the headlight, and which takes steam from the locomotive. The headlight is an arc lamp of entirely special design with a view to avoiding the injurious effects of the jolting of the engine. As the current generated is only for the use of one lamp, it is of low voltage, and can be readily handled with safety on any point while running.

THE STIRLING COMPANY'S BOILER TESTS.

The Stirling Company have issued a catalogue under the title of "An Era in Boiler Performance" which describes a test made on three Stirling boilers at the Waltham (Mass.) Bleachery and Dye Works. The test data were taken simultaneously but independently by the engineers of the Bleachery Works and of the Stirling Company. The evaporation performance was high, showing an equivalent per pound of combustible from and at 212 deg. F. of 13.03 pounds of water.

An error inadvertently crept into the exhibit note of the Stirling Company in our issue of May 20. The tubes of this boiler are all expanded directly into the drums in the ordinary manner instead of being screwed in as stated. It contains no screw joints except at the steam and water connections.

PRINTING TELEGRAPHS.

The Printing Telegraph News Company, of New York City, has been organized to make, lease, sell, etc., printing tele-

graphs and other instruments used in the collection and dissemination of news. The capital is $500,000, and the officers are Orlando J. Smith, G. W. Cummings, R. W. Nelson, and John H. Grant, of New York City and M. F. Gormond, of Scraalenberg, N. J.

FIXTURES WANTED FOR THE NEW LIBRARY OF CONGRESS.

Bernard R. Green, in charge of the building for the Library of Congress, is inviting proposals until June 13, for furnishing, delivering, and putting in place electric light fixtures and lamps.

UNDERGROUND CABLE TERMINALS.

The National Underground Cable Company, of New York, Boston, Philadelphia, and Chicago, has just organized a new department for the sole manufacture of Reid tubular terminal heads and telegraph cables, said department to be under the immediate supervision of Mr. Edwin S. Reid, the inventor.

WESTERN NOTES.

THE SUNBEAM INCANDESCENT LAMP COMPANY, of Chicago, have recently received an order for their sign lamps for a large illuminated sign designed and built by E. A. Robinson, for the Hopkins Theater, Chicago. In all 400 lamps will be used. The Sunbeam sign lamps were chosen on account of their small consumption of electrical energy, and it was found that with them a better effect could be obtained than with lamps of larger candle-power, the glare of which made the letters actually less distinct, especially at a distance.

THE SIOUX CITY ELECTRICAL SUPPLY COMPANY have been obliged to increase their factory to keep up their orders for telephone goods. Among the many orders now on their books is one for 1,000 dials and automatic central switches for the Automatic Telephone Switch Company; 800 drop manual board for the Home Telephone Company, of Sioux City, to replace a board they now have; 100 drop manual board and 70 telephones for Sheldon, and 75 telephones for Sibley.

ROTH BROS. & CO., No. 30 North Market street, Chicago, report that they are very busy supplying orders for their well-known fan motors, and also for their regular make of small dynamos and electric motors. From present appearances they expect to be kept in full swing for some time to come.

THE ADAMS-BAGNALL ELECTRIC COMPANY, of Cleveland, have opened offices at suite 1654 and 1656, the Monadnock, Chicago, and have secured the services of Mr. P. H. Polglase to attend to their interests in that territory. This company were awarded the contract for 750 series arc lamps by the West Side Park Commissioners on the 18th instant, when they awarded the contract for the equipment of the new arc lighting plant in course of erection at Garfield Park. A unique feature about this contract was that their bid for it was the highest made by the competing lamp manufacturers, the lowest bid being over $8,000 under what this company entered. As is naturally to be inferred, Mr. L. H. Rogers, the general manager of the concern, who piloted this matter through so successfully, is most jubilant over his success at securing so fine an order in the face of such strong competition, and for so young a concern.

DESPITE the fact that the Central and Western States have been blessed with a delightfully cool season, the Central Electric Company's sales of fan motors are thus far away ahead of last season's output. This is accounted for by the great popularity of the Lundell fan. Old customers placed orders for these while "The frost was on the pumpkins and the fodder in the shock," and new customers ordered because of the established reputation of the Lundell fans for simplicity and beauty of workmanship. The Central Electric Company have a complete line of fans for direct and alternating currents and for desk or ceiling use. A catalogue will be sent to any address.

THE PARTRIDGE CARBON COMPANY, of Sandusky, O., are making some large carbons, 3 inches by 18 inches, for the Pittsburg Reduction Company, of Niagara Falls. They are also making probably the largest carbons ever made for the Acetylene Gas Company, of Niagara Falls, 36 x 24 x 8 inches, which weigh 400 pounds each. These carbons are claimed to be the largest ever made. The company are also making a carbon telephone powder, the tests of which have been highly satisfactory. They are constantly receiving letters from consumers of their self-lubricating brushes, among which are some of the largest concerns in the electrical field.

THE METROPOLITAN ELECTRIC COMPANY are highly elated over the success of their wonderful catalogue. They have had orders for it from Her Majesty's Government, Turkey in Asia, the gold fields of Johannesburg, Australia, Central and South America, and pretty much around the entire globe, and wherever it goes it brings the highest encomiums for its comprehensive character and attention to details. Those that are interested in electricity in any way should get a copy, as this catalogue is a great help as a "ready reference book" and an "encyclopædia of everything electrical."

THE ELECTRIC APPLIANCE COMPANY are showing a particularly satisfactory line of fan motors for the summer trade. Their line of direct current apparatus includes the celebrated Dayton ceiling fans and their own Acme 110-volt direct current desk or counter fans. In alternating apparatus they are still handling the celebrated Meston line of desk and ceiling fans.

THE MASON ELECTRIC EQUIPMENT COMPANY, the Fiberite Company, and the Lafayette Engineering and Electric Works have removed to 1202 Fisher Building, corner of Dearborn and Van Buren streets, Chicago.

NEW YORK NOTES.

MESSRS. STANLEY & PATTERSON, of 32 and 34 Frankfort street, New York, have made arrangements to act as sole selling agents in the United States for Fleming's woven wire dynamo brushes. With increased facilities for manufacturing, there will be no delay in the future in filling orders for any size of brush, or any quantities that may be required.

MR. FRED PEARCE, 79 John street, of the old firm of Pearce & Jones, has the right of sale, either goods or patent, of a covering for incandescent lamps for advertising purposes. The device consists of a truncated pyramid, the sides of which are made of variously colored mica; the one end of the device has a stationary fan blade arrangement made of aluminum. Placed on any electric light bulb the heat generated causes the pyramid to revolve, displaying the different colors and producing a strikingly novel effect. The device costs nothing to run it and is everlasting. Mr. Pearce has long been identified with the electric trade, carrying a full line of everything appertaining to electric lighting, as well as manufacturing a large number of specialties.

THE ELECTRIC ENGINEERING AND SUPPLY COMPANY, 27 Thames street, F. M. Hawkins, manager, are shipping to the Corcoran Art Gallery, Washington, a 2,000 ampere triple pole double throw switch for the extensive electric plant located there. It is of the new and improved style, as noted in their advertisement.

THE DALE MANUFACTURING COMPANY have now been located for the past few months at their new quarters, 108 Greenwich street. They are selling and manufacturing electric and combination fixtures and fittings for factories, stores and office buildings and general interior lighting. Their Mr. O'Reilly reports business brisk. This firm manufactures for the trade only.

THE WESTON ENGINE COMPANY, Painted Post, N. Y., whose works were destroyed by fire on May 16, have leased a plant in Corning, N. Y., and are carrying on their work as usual with the exception of the manufacture of engines. They expect within a very few days to complete arrangements so that they will be able to fill orders with little delay.

MR. OBERLIN SMITH, the well-known past president of the American Society of Mechanical Engineers, is bringing out, under the auspices of John Wiley & Sons, a large and interesting book on the "Press Working of Metals." It is illustrated with 433 engravings. It has 276 pages and is sold for $3. As an authority in this field, Mr. Smith is unsurpassed, and his literary ability is well known.

NEW ENGLAND NOTES.

THE BRISTOL COMPANY, Waterbury, Conn., call attention to their electrical recording instruments in a small pamphlet just published. These instruments are made in the form of ammeters, voltmeters, and wattmeters, all of which make a continuous record of the amperes, voltage or watt output of a machine for 24 hours run. As the records can easily be read down to one volt and show the exact time when any irregularities may have occurred, the use of these instruments undoubtedly induces closer attention on the part of dynamo attendants.

Department News Items will be found in advertising pages.

THE

Electrical Engineer.

Vol. XXI. JUNE 17, 1896. No. 424.

ELECTRIC LIGHTING.

THE ELECTRIC LIGHTING OF NORWICH, ENG.

THE picturesque city of Norwich, England, is successfully lighted by electricity, and the lighting plant contains several features of special interest. The scheme of lighting is carried out by the Norwich Electricity Company, a corporation which has been enabled not only to pay a dividend, but to wipe off the whole of the preliminary expenses, and carry over a respectable amount towards a reserve fund after the first year's working.

The Norwich station was designed mainly by Messrs. Laurence, Scott & Co., of Norwich, Mr. W. H. Scott, of that firm, being personally responsible for the work. The illustration, Fig. 1, is a cross section, showing the general arrangement of the engine house, boiler house, the accumulator room, and the pump house. It will be seen that the River Wensum, a navigable stream, flows by the works.

The engines, dynamos, switchboard, accumulators, condensing plant, etc., were arranged by Mr. Scott, and have been shown by experience to be admirably devised with a view, not only to facilitate working, but also to the reduction of working expenses, the best testimony for this being that the company has, as stated, paid a dividend at this early stage. The installation is on the three-wire low-tension system, the pressure at the customers' lamps being 110 volts. Accumulators are used for the lightest loads, so that the station may be shut down at night, and they are available as a standby in case of need. In designing the station it was determined to lay down six sets of engines. All are of the Willans type, and are triple-compound. Three of these engines are of 100 indicated horse-power each, and each of these engines is connected to two "Norwich" dynamos manufactured by Messrs. Laurence, Scott & Co. These dynamos will work from 110 to 130 volts. Of the remaining engines three are of 135 indicated horse-power; the dynamos which they drive—one to each engine—are also of the "Norwich" type, made by Messrs. Laurence, Scott & Co., and will work from 220 to 250 volts. A seventh Willans engine, capable of giving 200 horse-power, has been more recently added, and is now running regularly. It is also coupled to a "Norwich" dynamo.

There is a separate ejector condenser to each engine, with an alternative branch exhaust to the atmosphere, and a nine-inch water main supplying all the condensers, and receiving water from a large cast iron tank, placed over one of the coal bunkers. Korting ejectors are used and the vacuum varies from twenty inches to twenty-five inches, according to the load. Water is pumped from the river into the tank by means of centrifugal pumps driven by electric motors of the "Norwich type.

The boilers are of the Babcock & Wilcox type; they are four in number. Each of the boilers contains 1,619 square feet of heating surface and thirty feet of grate surface; the tubes are four inches in diameter, and each boiler has eight vertical sections containing nine tubes, the length of tubes being eighteen feet; the working pressure is 175 lbs. per square inch. A Babcock & Wilcox economizer is also fitted. Feed water is taken from the tank before referred to, there being also a large settling tank at a lower level, and beyond this again a smaller one, in which the water is heated by the exhaust steam from the feed pumps. One of the boilers is provided with a means for burning liquid fuel, the injector being of the Holden pattern.

The main switchboard was manufactured by Messrs. Laurence, Scott & Co. There are horizontal omnibus bars at the back of the board, which can, by means of the switches, be connected together in any suitable way. Each vertical space between the posts in the main switchboard belongs to one plant. In the center are three vertical bars connecting the three-pole switches. These are for the double dynamo plants.

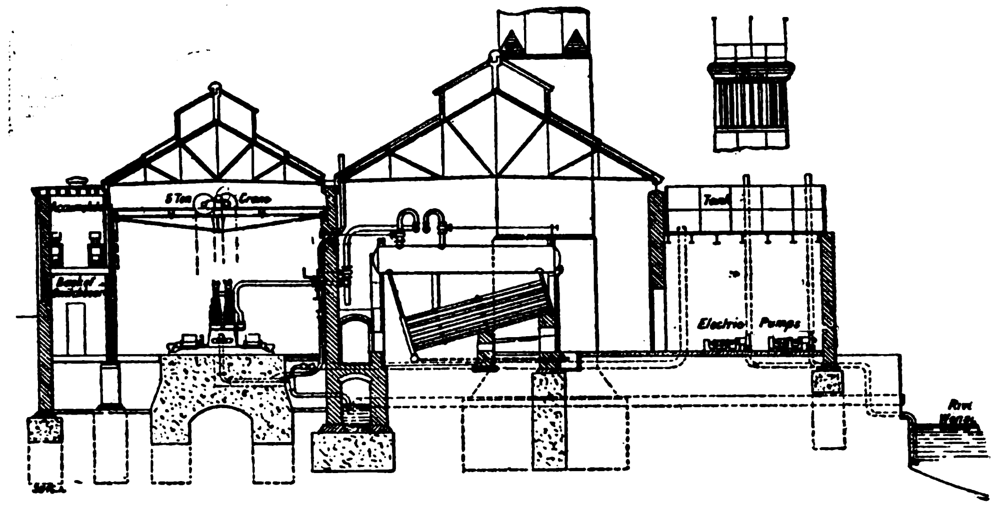


FIG. 1.—THE NORWICH, ENGLAND, ELECTRIC LIGHT STATION.—CROSS SECTION.

The current is delivered by means of feeders to three points in the city of Norwich, and when all the switches are filled in, the three tiers of switches in the switchboard will enable any of the dynamos to be switched on to any of these points.

Fig. 2 is a diagrammatic view of the connections for the accumulator switchboard. The current for charging the cells is taken off the ordinary omnibus bars and passed through the secondary winding of the armatures of the small motor dynamos. The motor winding of the armature can either be put on to the 110-volt or the 220-volt circuits through step resistances. During the early part of the charge it is a 110-volt circuit, but for the finish of the charge it has to be for a short time put on to the 220-volt circuit. This adds the extra pressure over and above the normal voltage on the mains required to charge the cells. They are charged during the daytime off the ordinary mains, a comparatively small current being used, the drop of voltage not being serious. As soon as the load comes on this charging is stopped, and as the load still increases the cells are discharged.

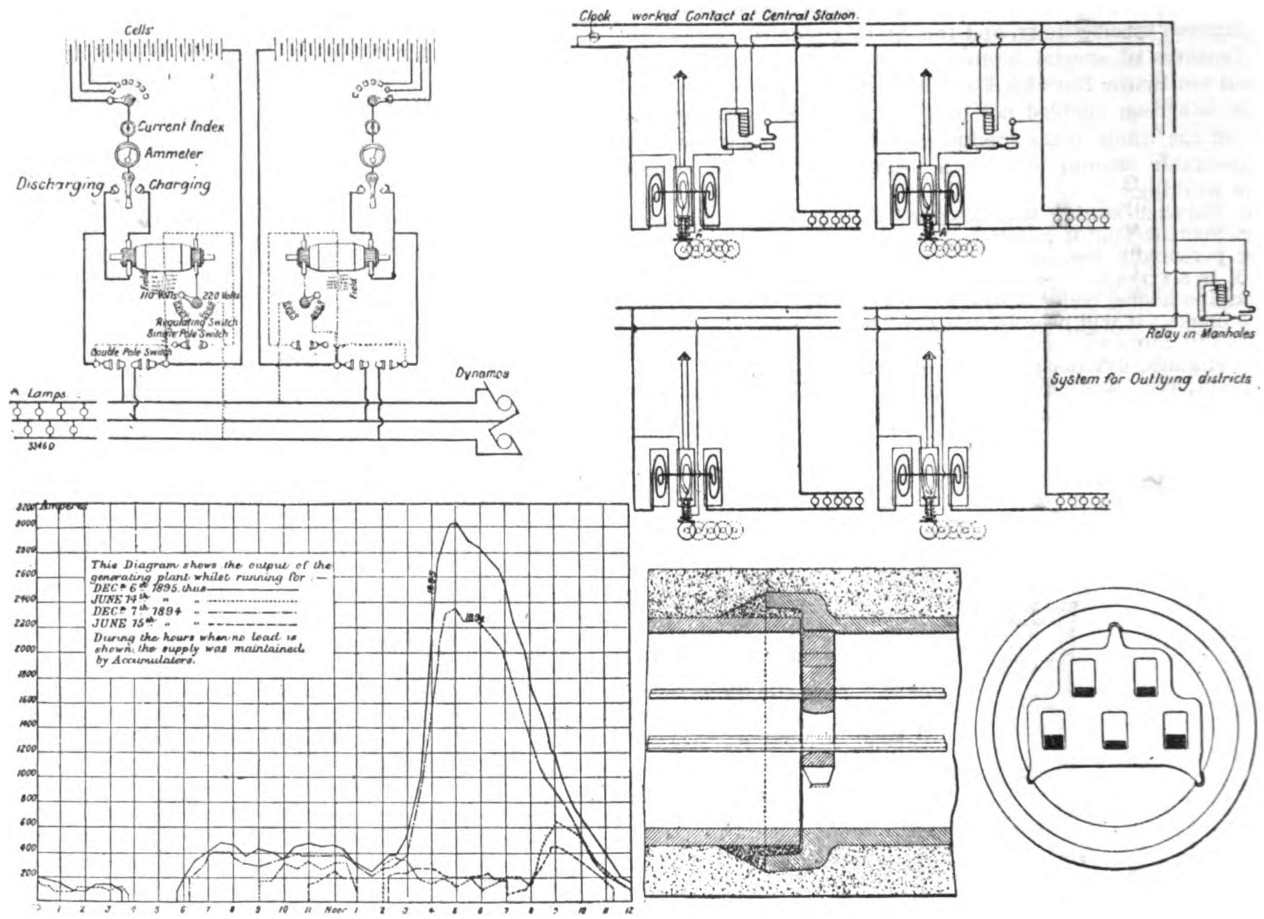
The first mains put down for the Norwich Electricity Com-

pany were on the concrete culvert system with bare copper, but during the progress of the work Mr. Scott introduced an entirely new system of bare copper culverts which has been found not only very much cheaper than the concrete culvert system, but is also claimed to be better in every way. The outline illustrations, Figs. 5 and 6, show the arrangement clearly. The high vitrified porcelain insulator is cemented, at the projecting corners only, into little nicks cut into the socket end of an ordinary sanitary drain pipe, as shown. Another length of pipe is then carefully cemented on, and the joint is cleaned inside. This forms a four-foot length of pipe with the insulator in the center. The projecting corners of the insulator are so arranged that the surface of contact with the pipe is very small, while there is ample space under the insulator for water to drain away and to allow for sag of the copper strips. Six-inch pipes are used for the ordinary distributing mains. These are threaded through the holes in the insulators, as shown in Figs. 5 and 6. The insulators for nine-inch pipes have five ducts or ways, three for distribution, and two for feeders, as shown in Fig. 6. The copper is not drawn in until after the conduit has been put down and finished, but draw wires are pulled in by means of long splines, one for each way. To put the copper in place a steel cable is pulled in by means of the draw wire, and with this cable—by means of a special connection—the copper strip is got into position without any difficulty.

Mr. Scott was an early advocate of the use of continuous current transformers for electrical distribution, but after studying them from every point of view, he now maintains that for ordinary town distribution they are not desirable. He holds that if the cost of the transformers, and of the highly insulated cables required for conveying the current to them, be put into bare copper and culverts, the same efficiency at full load can be obtained in practically every instance. This means a much greater all-round efficiency, as the loss in the simple conductors is reduced in proportion to the load. The up-keep depreciation is very much less with a simple heavy copper conductor, and, most important of all, the reliability is very much greater. These considerations have led Mr. Scott to condemn the continuous current transformer for ordinary distribution.

For obtaining the extra electromotive force for enabling the accumulator cells to be charged at points distant from the central station, however, he has found a modification of the continuous current transformer to come in very useful. The pressure can be raised from below the standard lamp voltage to the required amount for charging the cells. In order that the lamp voltage near the transformer station shall not be lowered during the time of charging, a feeder is taken back to a point near the feeding point from the central station. The current for charging the cells is then taken along this charging feeder, the slight drop in it being made up by the transformer.

An entirely novel arrangement of meters and system of charging for current has been arranged for the Norwich installation, and has been in actual working for over two years. Between an hour before sunset and eight o'clock in the evening the Norwich Electricity Company's charge for current for lighting is 8d. per unit. At all other times it is 4d. For motors it is 6d. and 3d. for the periods named respectively, except for large motors running continuously all day, for which only 3d. is charged throughout. This differential charge is rendered possible by the meters being arranged to integrate only half the amount of current supplied between 8 o'clock in the evening and an hour before sunset the next day. At other times the meters integrate the full amount of current supplied. To effect this the meters are of the periodically integrating type, and consist of a shunt coil hung between two fixed series coils through which the current to the lamps passes, as shown in the diagram, Fig. 3. This shunt coil is excited periodically, and as long as the current flows in it, it is deflected an amount exactly in proportion to the watts in the circuit which it is metering, falling back to zero every time the shunt circuit is broken. It is clear, then, that if this periodic deflection is made to move a train of wheels, the train can be so arranged that the meter will indicate the exact amount of electricity used. To do this it is necessary that only one movement (either the forward movement of the coil or its backward movement) should move the train round. This is effected by a little friction pad which is lifted by the little magnet A. so that it does not bear on the friction wheel whilst the shunt current is flowing. On the shunt circuit being broken, however, this little pad is dropped on to the friction wheel which forms the first wheel of the integrating train. This wheel is



FIGS. 2, 3, 4, 5 AND 6.—THE NORWICH, ENGLAND, ELECTRIC LIGHT STATION. DETAILS OF CONSTRUCTION AND OPERATION.

thus moved round every period an amount exactly in proportion to the amount that the shunt coil was displaced, owing to the electro-dynamic action of the currents in the wattmeter.

This meter, of course, requires some arrangement for making and breaking the shunt circuit periodically. This is done in the majority of meters in Norwich by means of a relay in the meter. These relays are in series on different circuits which radiate from the central station, the conductor for these circuits being in an iron pipe which is laid alongside the earthenware pipe culverts. The meters are so calibrated that if the shunt circuit is completed once every ninety seconds they will integrate exactly in Board of Trade units, and it is evident that if this impulse is sent only once in 180 seconds they will indicate only half the current which has passed through them. The differential charge is arranged in the following manner. There is a special clock at the central station which is set to automatically change the rate from 90 to 180 seconds, at an hour before sunset, and to change over again at 8 o'clock in the evening and 7 o'clock on Sundays. The adjustments are made, according to the calendar, at any time during the day. The clock automatically carries out the rest of the work.

The advantages of this system over other differential systems are twofold. Firstly, there is no complication in the accounts, which are simply rendered according to the meter readings at 8d. per Board of Trade unit; and, secondly, that customers get charged for their current as nearly as possible in the same proportion it costs the company to supply it. Thus, offices, shops that close early, etc., which only require light some 150 to 200 hours per annum, and always take their light at the time of maximum load, are charged at the comparatively high rate of 8d. per unit. Before 8 o'clock in the evening the maximum load has gone off, and the station has ample reserve, so that any additional customers that come on only at this time do not increase the capital charges. Further, places of entertainment, churches, etc., although their number of hours running is small, can yet be supplied profitably at a very cheap rate. They get nearly all their supply at 4d. per unit, while those who require light from dusk till, say, 11 o'clock at night, such as clubs, public houses, etc., get their supply at an average rate which diminishes according to the increase of the number of hours that they require light per annum. These are just the customers that are most profitable to an electric lighting company, even at a very reduced rate.

The Norwich Electricity Company have been at work sufficiently long to thoroughly test the design and workmanship of the plant, and the result appears to have been most gratifying, both to those who were responsible for the designing and construction of the arrangements, and to the shareholders of the supply company, and to Mr. F. M. Long, the managing engineer of the company, who has had charge from the beginning both of the installation of the work and the running of the station.

The works' cost of the electricity supply during the year 1894 came out 2.19d. per unit, and during 1895 at 1.90d. per unit. This was including the coal, oil, waste, and other stores, salaries of engineers, and wages, repairs, and maintenance, including also maintenance of mains and other distributing expenses. The coal, oil, waste, etc., came to 1.28d. per unit in 1894, and in 1895 to 1.01d. In considering these figures it must be remembered that Norwich is a long way from the coal districts, the average price paid for fuel being some 16s. per ton.

In Fig. 4 we give a diagram showing the load for two midsummer and two midwinter days in 1894 and 1895. This will be of interest to those of our readers who are engaged in similar work.

From figures submitted by those engaged in the work, it would appear that on the first year's working (1894) a profit of £1,813 was made, the revenue from sale of current and meter rents being £3,790. For the year 1895 a profit of £2,998 was made, with a revenue of £5,845. The profit for the last year was just 5½ per cent. on the capital expenditure.—Abstract from "Engineering."

A Day with the Founders of Ampere.

BY

T. C. Martin

I.

In the early eighties, the present writer, in the performance of editorial duties, happened to hear that two young fellows, fresh from Columbia College, had taken up the then novel problems of electric motor building, and were actually ready to sell motors of an efficiency that was remarkably high for the times. A visit to a small office room in the Tribune Building was enough to prove that a distinctively new departure was being made, and that these two enthusiastic youths, whose engineering skill and training were reinforced by special aptitude and peculiar foresight, had designed a motor of remarkable qualities. As a matter of fact there were three Columbia graduates interested and contributing, namely, C. G. Curtis, F. B. Crocker and S. S. Wheeler, and it is but simple justice to say that the work of those three young men is part of the solid foundation upon which the great motor industry of to-day has been reared. Up to that time, motors were, as a general thing, fearfully and wonderfully built, and, according to some figures made by Mr. Edward Weston, then,

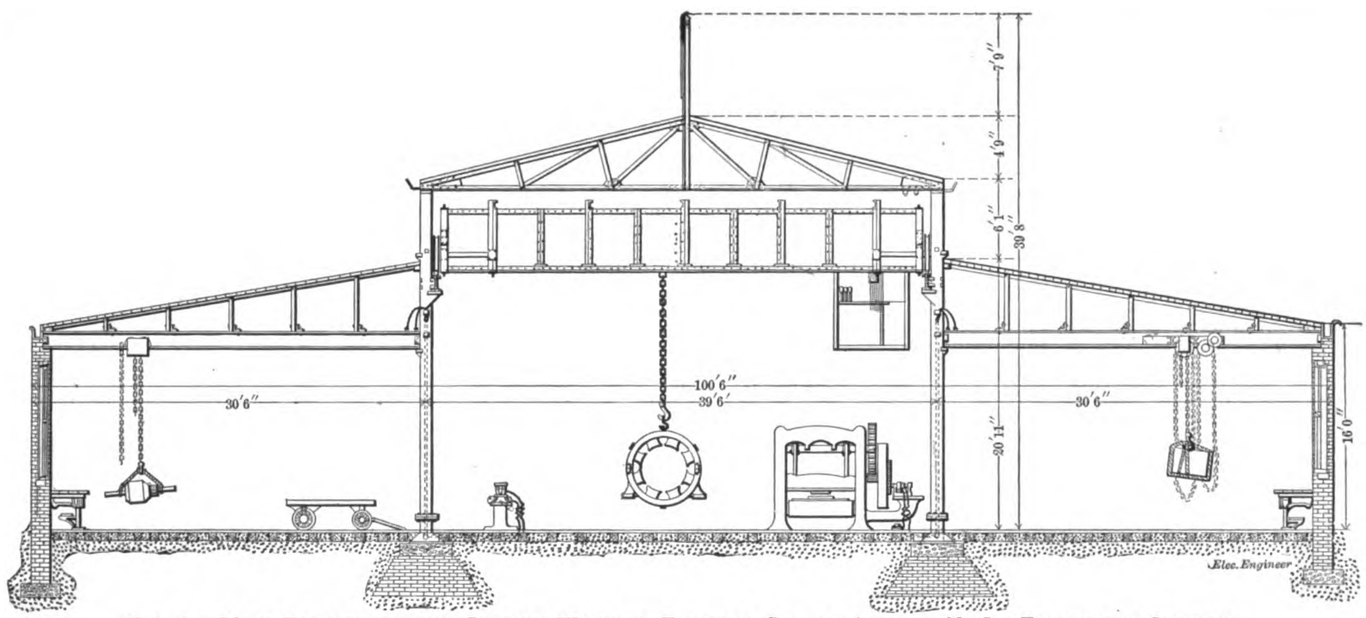


FIG. 2.—MAIN FACTORY OF THE CROCKER-WHEELER ELECTRIC CO., AT AMPERE, N. J.—TRANSVERSE SECTION.

as now, a leader in the electrical arts of construction and measurement, there was not one on the market that had an efficiency of more than 16 per cent. They were all small and all of delicate constitution. Almost all of them were designed to run on battery current, and even the three motor "musketeers" named above counted it no mean thing to have improved on the methods of supplying and replenishing the electric "growler" or battery jar. But the chief idea of Messrs. Curtis, Crocker and Wheeler was that the central station circuits would in time multiply and ramify like water pipes, and Mr. Wheeler, who had done pioneer work in the lighting field and on the Edison mains in New York and other cities, was tenacious in his belief that the thing to strive for was a motor that could be clapped on the circuits just as easily as a lamp.

Nearly fifteen years have rolled by, with tremendous and kaleidoscopic—or even kinetoscopic—changes in the electrical field. It is above all things true that the electric power art has gained an enormous ascendency, and has begun to split up into a number of new departments, each of which is a differentiation from the common stock. The lighting art has not waned but waxed; yet there has grown upon the electrical consciousness the conviction that as lighting lasts but a few hours in the twenty-four, while power may be needed every second in the day, it might be well to devote to the motor some of the energies hitherto concentrated on the lamp alone. Putting aside the electric railway industry, as an art now altogether apart, we may safely say that the chief opportunity for the sale of current to-day lies in the installation of motors; and thus we find justified the early optimism of which brief mention has been made above. It is seldom given to a pioneer or forerunner to see the accomplishment of his plans and dreams, and it is therefore noteworthy that, amidst all the changes and vicissitudes of the growth of the motor business, those who had so much to do with its inception have played a leading part. Dr. Wheeler helped to give New York her subways; Professor Crocker is at the head of the electrical studies in Columbia, but their united names remain associated with the great motor-building art and with one of the largest electrical factories in the United States.

II.

If the Greater New York were to include all the territory that honestly belonged to it, part of Connecticut and half of New Jersey would be under the rule of her City Hall. Hence the pretty little suburb of Ampere is as much a part of the metropolis as Broadway, and it is as easy to reach it as Central Park or Grant's tomb. It is now some years since a rap-

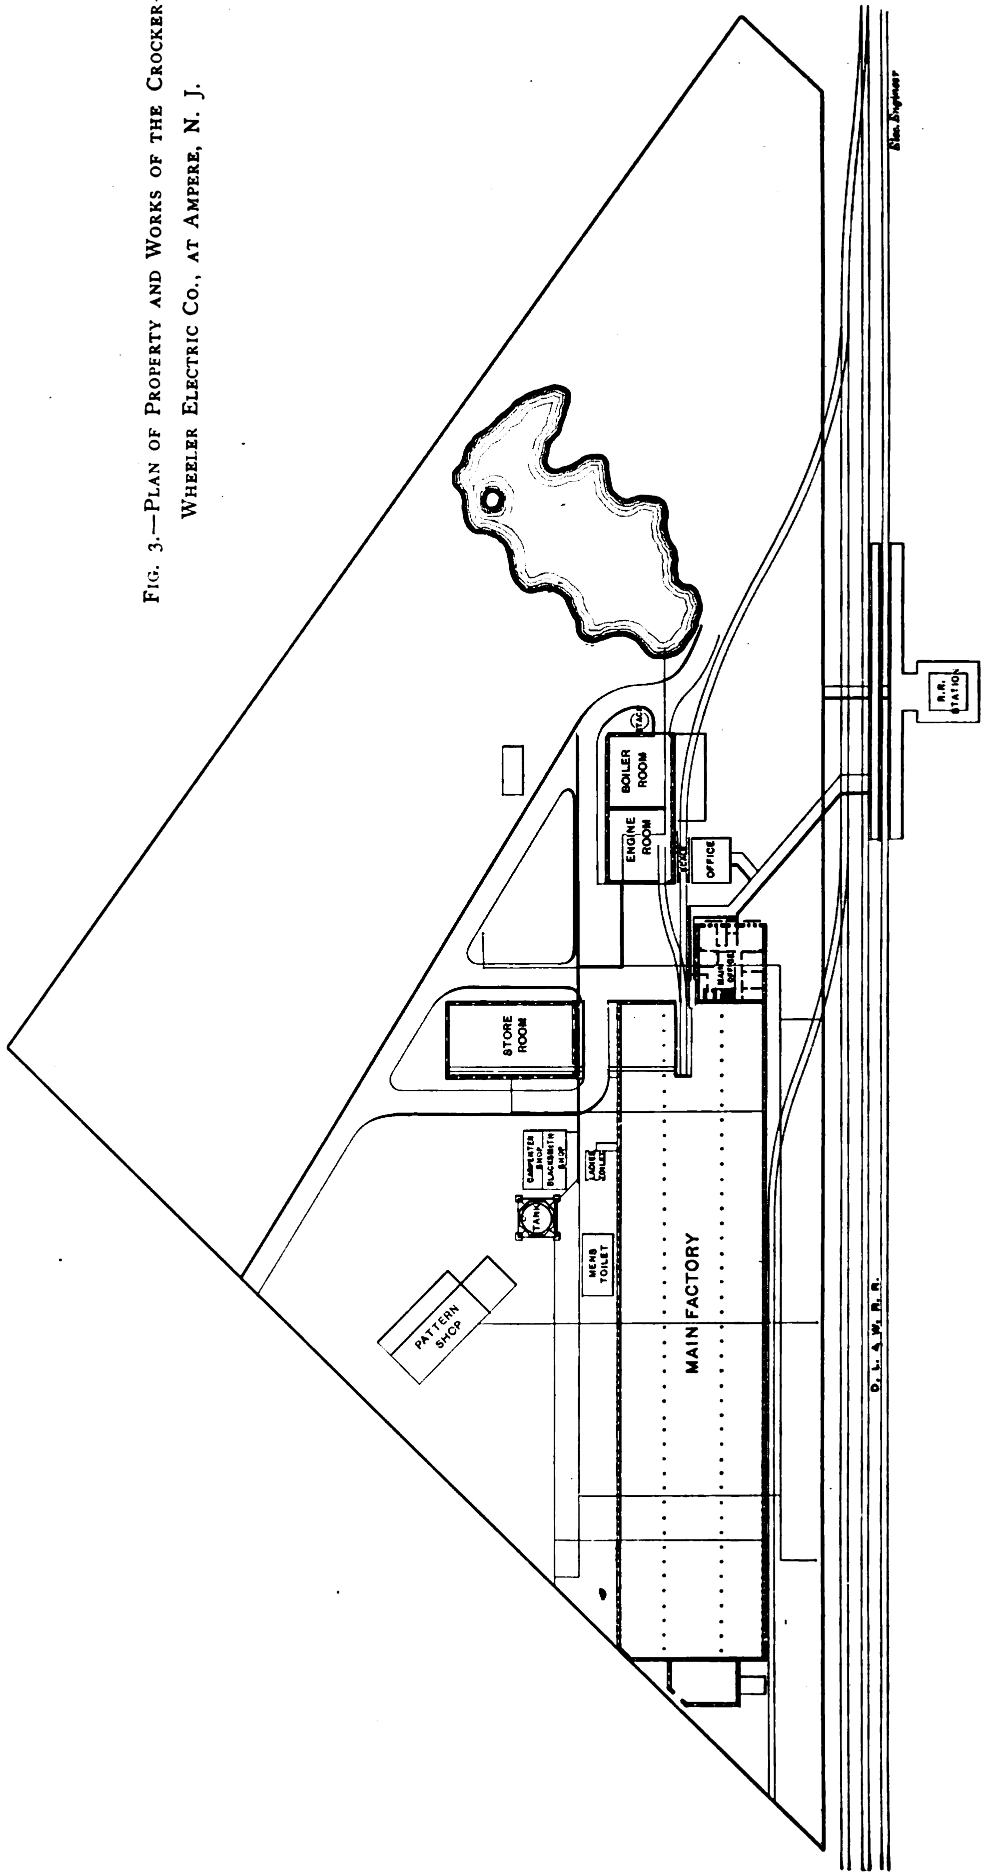

Fig. 3.—Plan of Property and Works of the Crocker-Wheeler Electric Co., at Ampere, N. J.

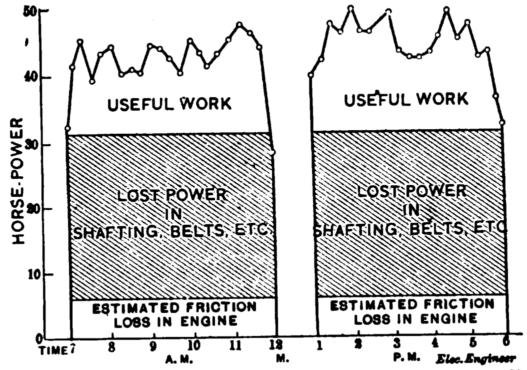
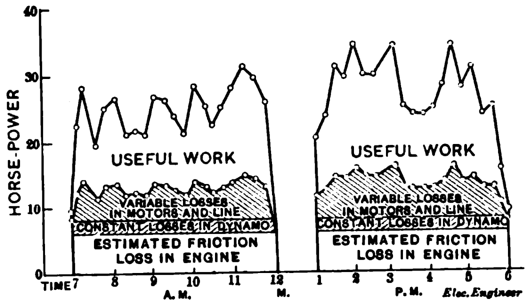
idly growing demand for their product caused the Crocker-Wheeler Electric Company, after several expansions in the city, to remove their works to the Jersey suburb, where the railroad opened a station for them, to which they at once gave



Power Test, Factory "K," Central Stamping Co., Brooklyn, N. Y. Average I. H. P., 44.1.



Losses in Same Plant with Electric Transmission. Average I. H. P., 25.7.

Fig. 4.

the name of the famous French physicist. There they took possession of works that were well adapted to their purpose, though not specially designed. The main advantage was that the company, which at an early stage of its career had turned out fan motors by the thousand, now found itself swamped with orders for "power" motors in equal number and often in very large sizes, and it was able here to meet just such demands.

One of the main features of the factory was the demonstration of the ease and facility with which it could be operated by the direct application of electric power. Reference to this was made from time to time in the columns of The Electrical Engineer, to which Dr. Wheeler also furnished a valuable series of articles on motor-driven tools. To-day the subject is well within the range of "practical politics," but at that time the argument had to be made from the ground up, and a vital, typical example, such as this factory presented, was of inestimable importance in shaping public opinion and determining the shape of events.

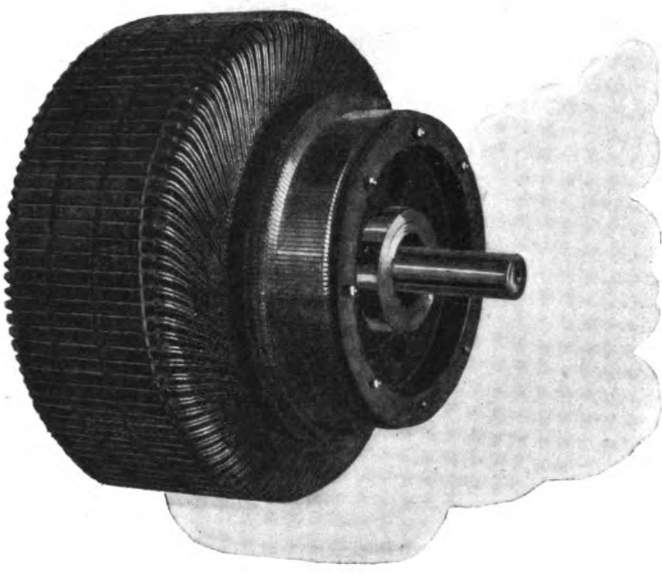


Fig. 6.—Armature for Direct Connection on Engine Shaft.

Early in 1895, just when the company was loaded down with orders and contracts for spring delivery, the factory was destroyed by fire. It was a Sunday, when nobody but the watchman was around, but that only helped the progress of the flames; and in a few brief minutes everything was in wreck and ruin. President Wheeler received the news at a time of bitter domestic affliction in the loss of his wife, whose interest in the factory had been as devoted as his own.

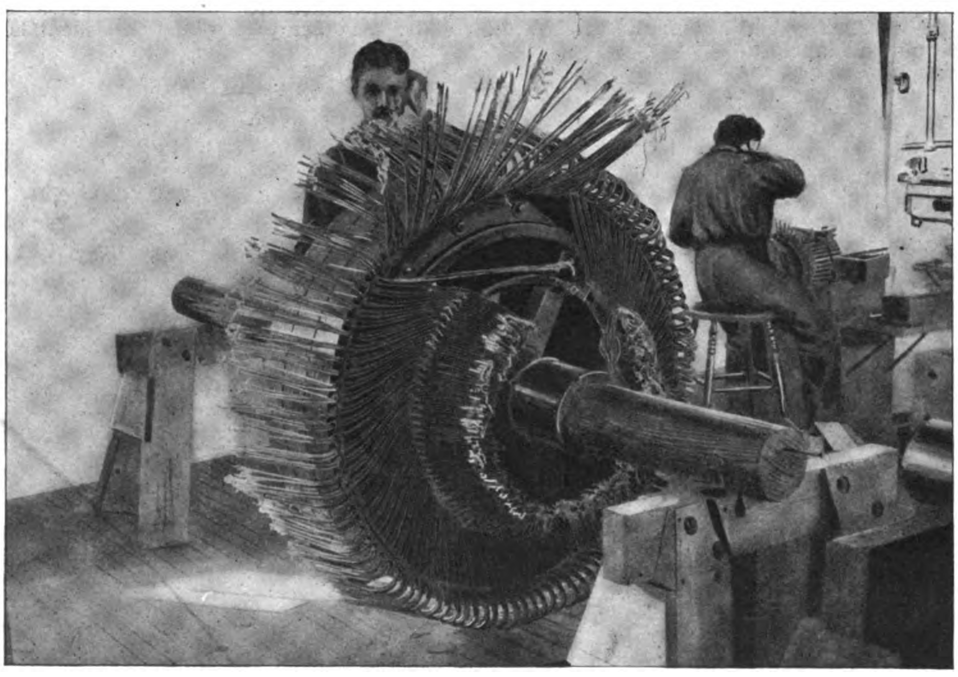

Fig. 5.—"Direct Connected Type" Armature Core, Partially Wound.

III.

Within a week after this disastrous fire, the insurance was adjusted, and the work of restoration began. Part of the old main shop was patched up, the summer weather was favorable,

motors were hitched on to available machinery, gangs of workmen were employed night and day, and within three months the company had emerged from chaos and was again abreast of its orders. But the necessity for a new factory was imperative, and by dint of strenuous effort new shops and a fine new office building were completed by the end of the year, the officers and engineering staff acting as architects. It is obvious that while the fire had been a severe blow, it also permitted the executive of the company to carry out with more vigor and thoroughness than ever its rooted ideas as to the use of electric power in a factory.

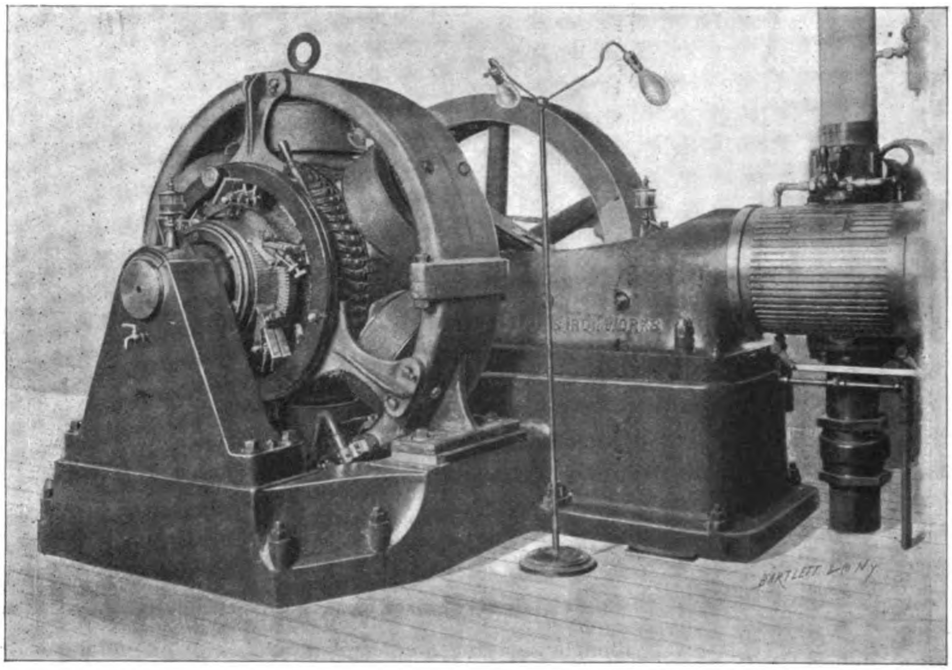

Fig. 7.—Dynamo, Direct Connected to Shaft of 80 Horse-Power Engine.

In some respects the old factory had had merits in showing how electric power could be adapted to conditions, all of which were not favorable, but in the new factory the conditions could be molded so as to satisfy any one that a manufacturer who did not equip with electric motors was limiting himself in the quantity and quality of his output.

The new factory, to which the present article is devoted occupies the same situation relatively as the old one, being only eleven miles from New York City on the Montclair branch of the Delaware, Lackawanna & Western Railroad, beside which the buildings align, and from and to which cars are directly switched, while a passenger service of twenty-five trains daily each way renders access easy alike to visitors and to the staff of the selling department in Cortlandt street.

Electrical factories have long ceased to be a novelty, and the public is now familiar with their main processes, all of which bear a family likeness; but a good deal that is of interest can be learned at any time from the study of a typical establishment, and especially from a well conducted place where new things are continually being tried. The new Crocker-Wheeler factory may be taken up in three sections, namely, the office building, the power house and the shops proper. Each of these departments is in evidence in the fine supplement accompanying this issue of The Electrical Engineer, and each will be later considered in detail. It may be said in passing that the view of the works from any point of the surrounding country is very attractive and imposing, the offices and power plant first catching the eye, and then the long main shop. The length of the property is, in fact, such as to have rendered difficult the securing of the large photograph from which the engraving in our supplement is taken.

IV.

The office building is a solid, handsome structure in red brick and stone, 50 feet by 47 and 45 feet high, four stories, and has been designed throughout with special reference to smooth management of the works and to facilitating the work of the engineering and drafting departments. On the main floor, on the left, as one enters, is a convenient suite of offices, where President Wheeler and his staff may be found. Across the hall are the treasurer's office and bookkeeping department. The chief engineer, in direct touch with Dr. Wheeler, has his office also on this floor, and the workmen's entrance to the shops in the rear is so arranged that all pass through the bookkeeper's office and are registered or paid without any disturbance of the quiet, orderly routine of the place. On the second floor are drafting, blueprinting and photographer's rooms, while provision has also been made for a fine library, lavatory, locker rooms, etc. Above this floor is another devoted to minor uses, including storage of plans, office material, etc. Descending the stairway to the basement, a large portion is seen to be given up to the laboratory and experimental testing work in charge of Mr. Dunn. Any work brought here can be attended to without derangement of the shops. Some of us have often seen a whole factory "stood on its head," while a small experiment was being tried, but here the division between apparatus for test and apparatus for sale is absolute. Every care has been taken to provide facilities and insure accurate results. Another part of this basement is occupied by the bicycle room. At one side it communicates by tunnel subway with the power house, whose circuits run to it, and on the other side the tunnel is continued so that the conductors reach the main shop and there fan out for the delivery of their current.

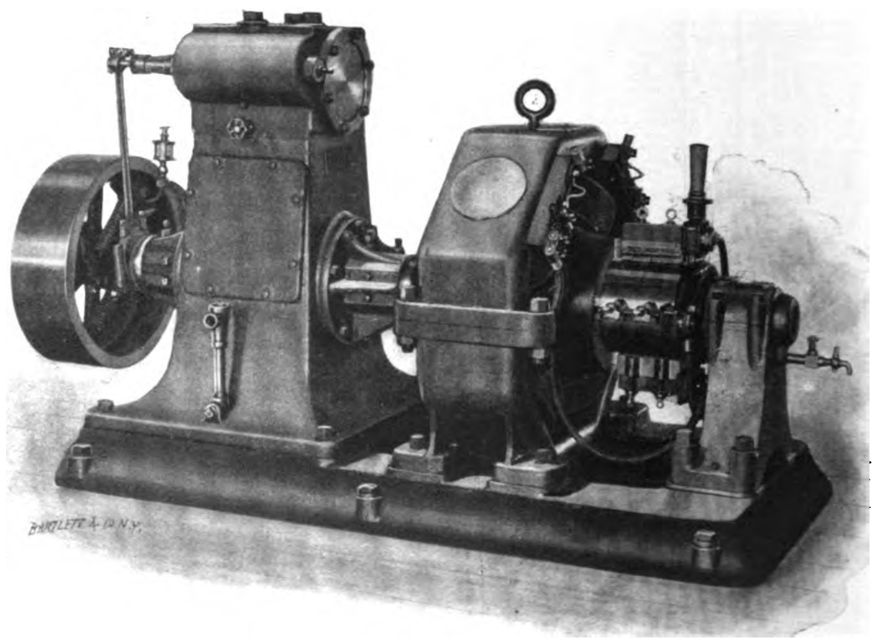

Fig. 8.—Generator, Direct Connected to Case Engine.

Provision has also been made in this building for the preservation of records. A fireproof chamber, about ten feet

square, runs up through all the floors, surrounded by air spaces and protected by brick arching. Here, in these safety vaults the papers and records of each department are put. The whole interior construction of the building is of the slow-burning type and it is provided with sprinklers throughout.

V.

The power plant of these extensive works is smaller than one would imagine or expect, but herein lies one of its chief beauties in the eyes of the company's officers, who point to it as a concrete example and embodiment of their theories as to the economical generation and consumption of power when electricity is the distributing agent and motors are the translating devices at the point of consumption. In the boiler room there are three ordinary boilers, each of 125 horse-power, the steam room being separated from the dynamo room by a short flight of stairs and a dividing wall. Only one boiler is used at a time. In the dynamo room, conveniently disposed, is, first, a fine Hewes & Phillips Corliss engine of 125 horse-power, belted to an 80 kilowatt Crocker-Wheeler generator. Then comes a McIntosh & Seymour high-speed engine of 250 revolutions, direct connected, to a 100 k. w. C. W. generator at 110 volts, and also belted in tandem to an 80 kilowatt, 220 volts, and a an 80 kilowatt, 500 volts, these three making a complete outfit for current for testing at the standard American voltages. Besides these engines, there is an Ames of 40 horse-power intended presently to run direct connected, but just now belted to a 25 horse-power Crocker-Wheeler dynamo for night work. At one end of the room is a neat slate switchboard, to which all the circuits are led, for connection to the subway, entrance to which is made by a stairway at its rear. Extending over all the machinery is a traveling crane supported on the roof trusses for handling machinery.

In connection with the power plant must be mentioned the fire equipment, one notable item of which is the Standard Worthington fire pump, capable of sending out four full streams. The conspicuous water tower and tank, standing fifty feet high, is of 32,000 gallons capacity. The well is 231 feet deep, 8 inches in diameter, equipped with a deep well pump 75 feet down, operated by a 2 horse-power C. W. motor. This combination gives a yield of 1,500 gallons per hour in the tank. The water rises naturally to within twenty feet of the surface of the well.

There are seven fire hydrants on the grounds connected to the tank and the fire pump. With the pump not in action, the tank will supply the hydrants for one and one-half hours.

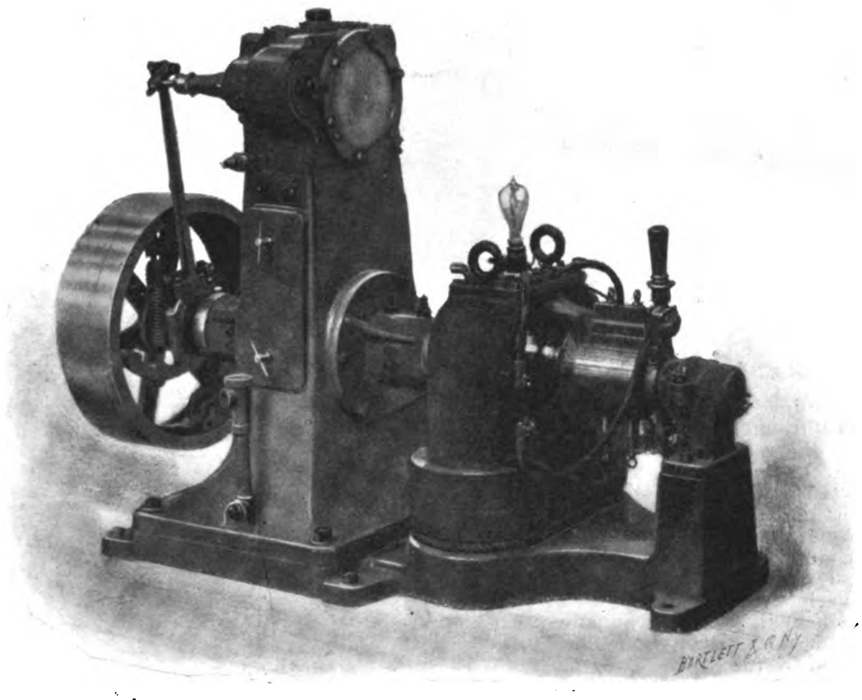

FIG. 9.—GENERATOR, 4 KILOWATTS, DIRECT CONNECTED TO ENGINE.

Throughout the buildings there are no fewer than 1,500 standard sprinkler heads, and the tank is fifteen feet above the highest of them. The tank is connected to the sprinkler system and the hydrants by several discharge pipes.

Returning to the subway at the back of the power house switchboard, it will be noted by an observant visitor that it slopes somewhat toward the foot of the engine room stairs. This is done for drainage purposes, should any water get loose anywhere, and there is a steam siphon to blow off any such liquid intruder. The subway system is wide enough and high enough to walk through, the conductors being carried on the side wall until they reach a manhole under the shop floor, the steam heating pipes being supported on the opposite wall. When they reach the shops the conductors travel along the tops of the roof trusses, on ordinary glass line insulators, the steel shanks of which are bolted directly on to the trusses. It would be difficult to devise a better or more simple method of interior distribution for this class of work.

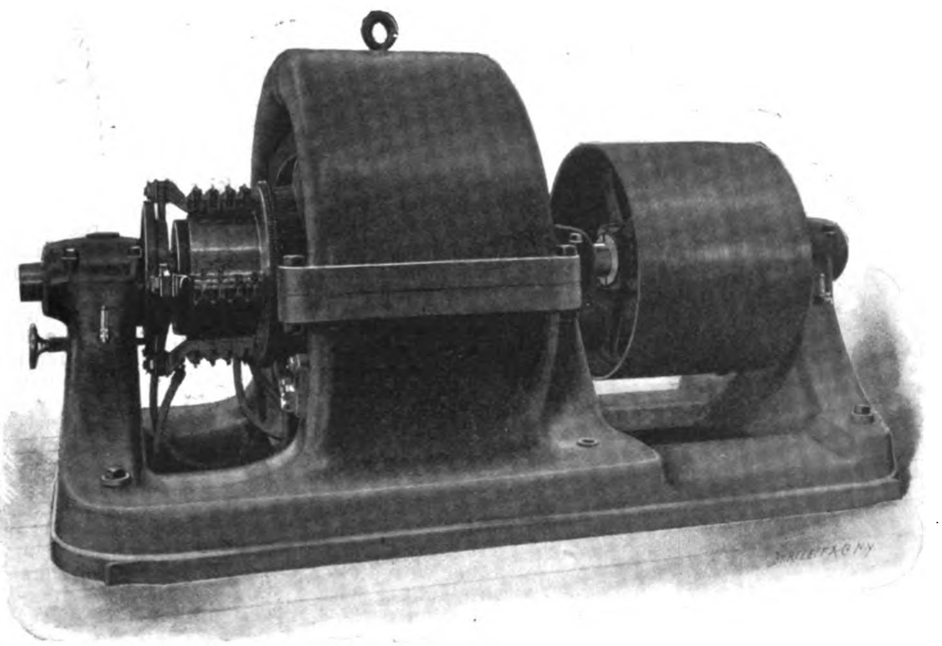

FIG. 10.—250 HORSE-POWER MOTOR. WEIGHT, 15 TONS.

VI.

As part of the power house and testing service, it should be mentioned here that the wiring consists of three pairs of cables running from the switchboard to the testing room in the main building with branches to the laboratory in the office basement, these three pairs furnishing the three separate voltages, supplemented by suitable circuits for controlling the fields of the dynamos. In addition to this, there is the regular wiring for the office building in tubes, and there is also the shop wiring. The latter consists of one pair of cables reaching from the switchboard to about the centre of the shop and terminating on an ordinary slate panel board where there are

fuses through which four circuits run to the four quarters of the main shop building, and two cicuits to the outlying buildings.

The taps for lighting and power are taken off through porce-

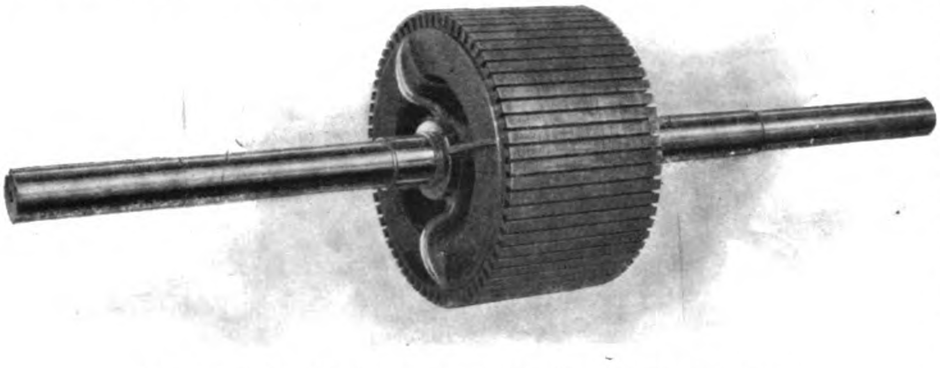

FIG. 12.—CORE AND SHAFT RING-TYPE WIRE-WOUND ARMATURE.

lain fuse blocks attached to the iron columns of the shop, and thence through small holes in the columns and down the inside of the columns to a point below the surface of the floor, where they come out through other holes cast like those just described above, in the bases of the columns. They now, at the base, enter wooden troughs laid under the floor in the cement. They come up through the floor at various points where desired, through small auger holes made directly under the different machines to be operated by the "juice."

VII.

The main shop building is of interest, not alone to electrical engineers. It is a low-lying but striking edifice, with a remarkably busy and business-like air about it. It is 450 feet long and 100 feet wide, and if we add fifty feet for the office building, to which it is closely joined, the front presented is full 500 feet in length. The ridge pole from one end to the other is followed by a huge sign, eight feet in height, and legible at a great distance. This sign is massively supported by the king posts of the roof trusses, which were extended upward through the roof for the purpose. Seen at a remove of a few hundred yards, the factory appears to be closely environed by green fields, but an inspection near at hand re-

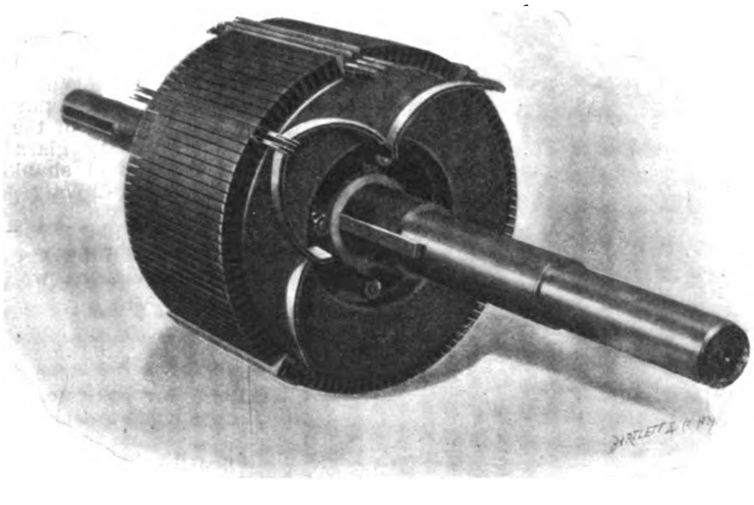

FIG. 14.—TWO-CIRCUIT BAR-WOUND ARMATURE, SHOWING CONNECTION DETAILS.

veals the railroad tracks and switches, one of which passes over a railroad scale and then into the building, where the traveling crane meets and extends over it.

There are many special features about the construction of the building, whose architects and engineers have realized that it is the first of its kind where sundry contradictory conditions had to be harmonized and turned into advantages with the aid of electricity. For example, the item of the floor involved many considerations of novelty. It was decided to put down a floor that in itself would be heavy enough to serve as a foundation for any machinery, so as to obviate both the cutting up of the floor for masonry and to facilitate the hauling around of the heaviest loads on plain roller trucks without laying industrial tracks on it for hand cars. As a result the floor is like rock. It is built up of 4 inch by 6 inch chestnut sleepers, laid in Portland cement concrete. Over this is a finishing coat laid on with the trowel and top dressed with tar. On this again is laid two-inch spruce planking and above it one and one-half-inch finished maple. Objection might be raised with some reason to the risk taken of damaging the surface of such a floor by heavy stuff, but it must not be forgotten that the electric overhead crane provides an aerial trolley system for just such material; hence the floor remains in good condition all the time.

The whole floor is most beautifully lighted up by means of

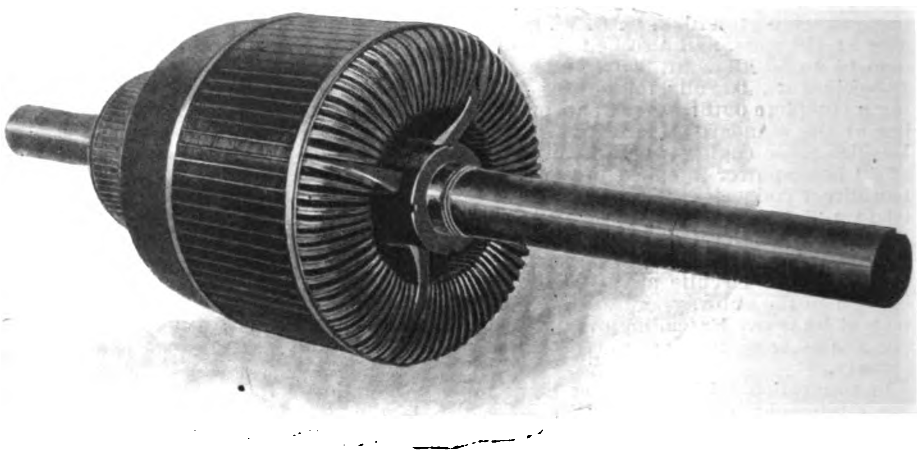

FIG. 13.—RING-TYPE COMPLETED ARMATURE.

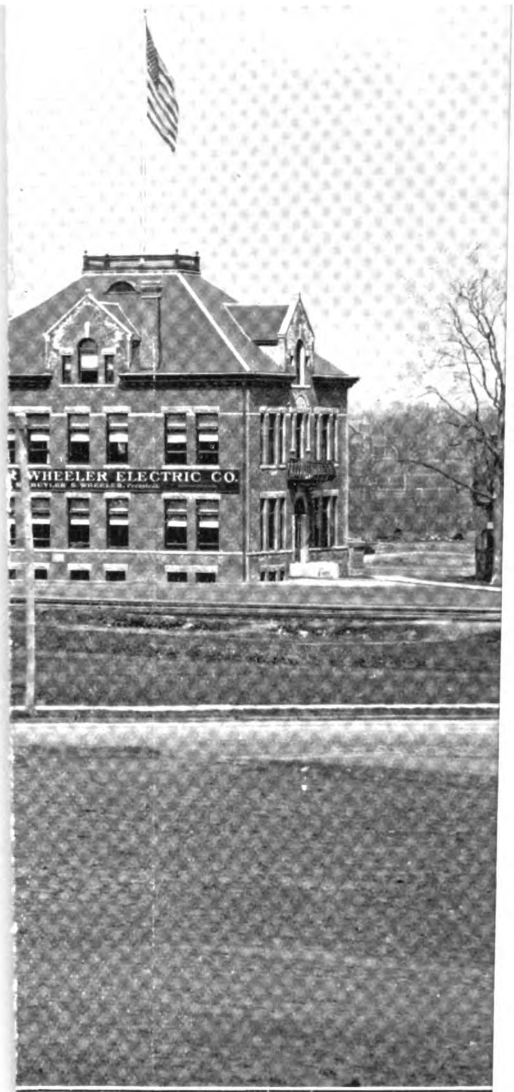
its large side windows and its ample monitor roof, but other modifications in ordinary factory structure have been introduced, tending to strength and lightness. The usual construction of the side trusses of a roof was varied with the object of furnishing trusses, the lower members of which could support trolleys for hoists having a capacity up to four tons. By the employment of fifteen-inch light beams, for the under members of the lean-to trusses and a very light angle iron for the upper members supported by vertical pieces of angles iron, the roof trusses were made with a very little increase of weight, yet with a lower member that would easily carry a large and powerful hand hoist. These roof trusses are ten feet apart. The transverse sectional cut of the main building shown on one of these pages illustrates admirably the features of the central traveling crane and the side hoists, in their relation to the trusses and as regards their own proper functions. It is certainly not the least interesting and instructive thing in the worlu to see the electric crane traveling from one end of the shop to the other with a twenty-foot lathe, like a lion making off jauntily with a young calf in its jaws. The amusing part of this performance is to see the lathe go on with its work. The little motor running it is in the bed, under the headstock and is geared directly to the main spindle and current reaches it in this position from the crane trolley. While in this attitude the lathe will turn off a piece of steel shafting of its full capacity, and will go on with the work quite nonchalantly, the spiral of cutting simply curling off to the floor. Paring apples for dinner in a balloon or peeling potatoes under water could hardly be more unusual and spectacular, but such things help to convey to many people of



RE, NEW JERSEY.

lethargic imagination the ideal of what is possible and feasible.

VIII.

The main shop is, of course, properly divided up into sections. On one side a large amount of building up and special tool and machine work is done, as the cuts in our insert show. At the centre of the floor is a store room of the most liberal character, divided into groups and copiously supplied with every detail. At the end furthest from the office building, a gang of motor-driven punches and stamps prepare armature discs and other sheet metal for use, and all along the eastern side are armature winders, banks for testing, machines for turning brass screws and binding posts; and all the facilities for assembling generators, motors, rheostats, starting boxes and the other parts necessary for the operation of the apparatus. The scene is always animated to a degree. Going around, one notices an ingenious system of "Works Orders" in use, with which to identify and follow up the work. Every piece of work carries the details and certificate of its birth in a little bag tied around its neck. No matter what it may be, each piece of work going through the shops has its special "Works Order" made for it very fully and very descriptively, by the assistant engineer, who has charge of the records and specifications. In the case of a single piece of apparatus, this blue envelope with brass tag may be seen attached to it wherever it may be in any part of the shop. In the case of a batch, the envelope goes with the crowd, so to speak. It is not to be imagined that the works order is a brief outline; it is more like the patent specification which any intelligent workman is supposed to be able to take and interpret fully by himself.

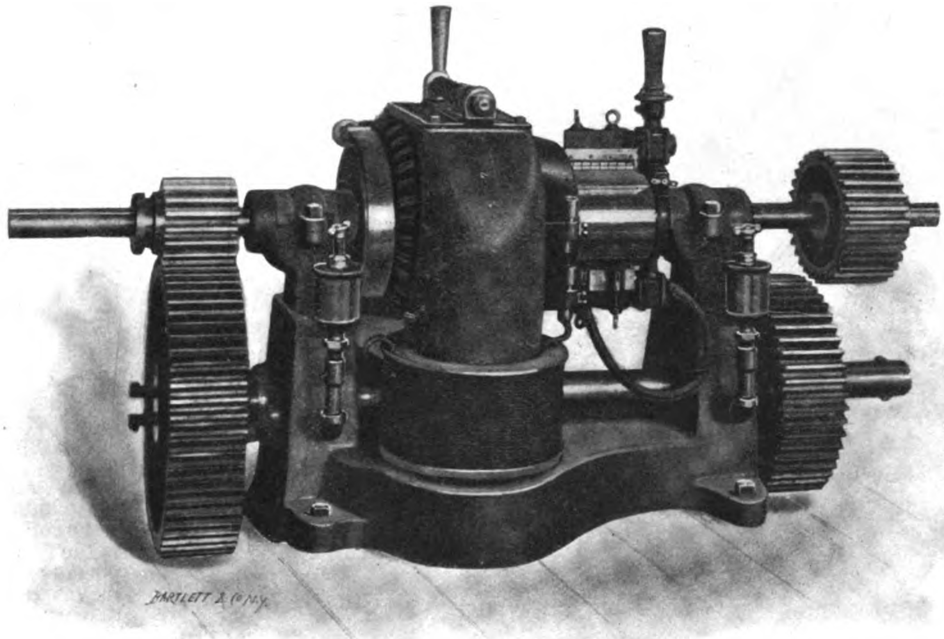


FIG. 15.—10 HORSE-POWER AUTOMATIC BRAKE MOTOR FOR OVERHEAD CRANES.

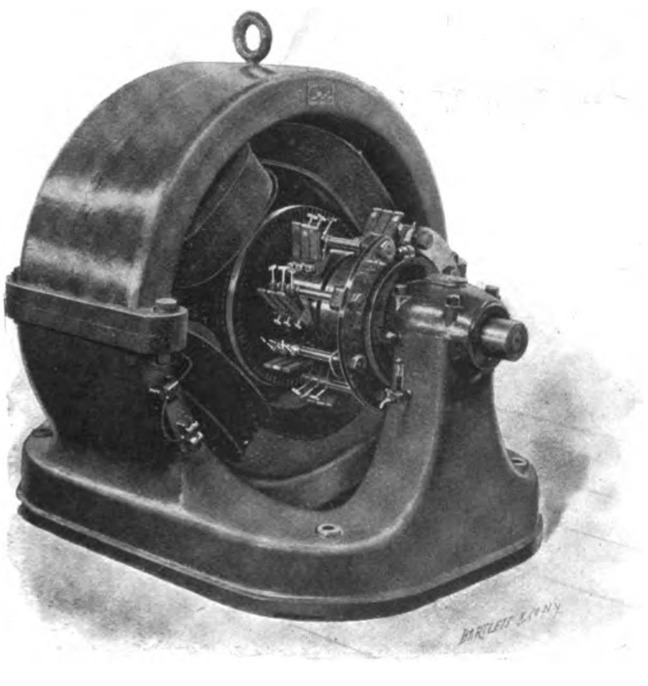

FIG. 11.—100 HORSE-POWER DYNAMO, WEIGHT, 16 TONS.

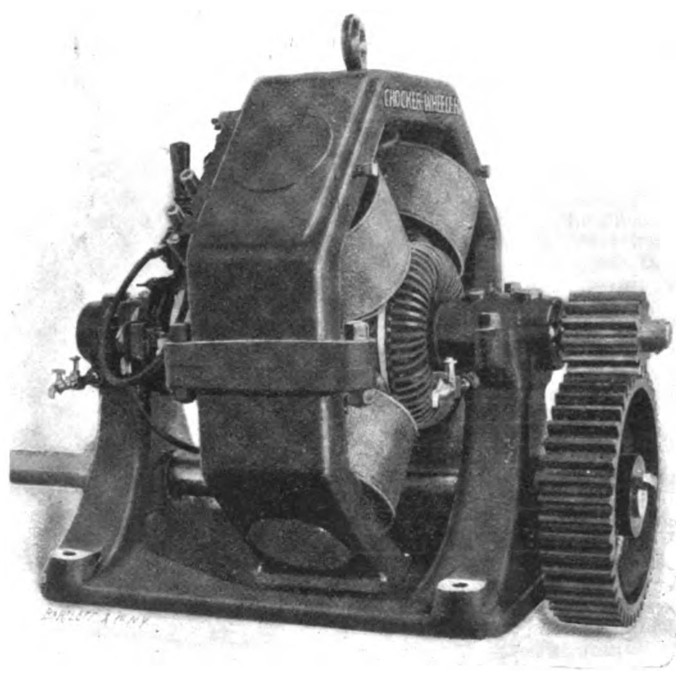

FIG. 16.—15 HORSE-POWER SINGLE-REDUCTION GEARED MOTOR.

"Shipping Orders" are, of course, a very important and separate detail. This part of the work is managed from the headquarters in Cortlandt street, but by means of the telephone line an extra shipping number can be obtained at once if necessary for some special thing and the goods may then be sent out.

These orders all emanate thus from one desk, in charge of Miss Hamilton, the experienced order clerk, and to that desk everybody concerned in the shipment of the goods is responsible for their dispatch.

Outside the main shop there are a number of supplementary and subsidiary buildings and departments, such as the pattern shop, carpenter shop, buffing shop, forging shop, etc. In all of them the leading principle and idea is to drive the tools by motor, so that the absence of belts, shafting and pulleys which at first struck the casual visitor as a curious thing soon comes to be accepted as the right and only way.

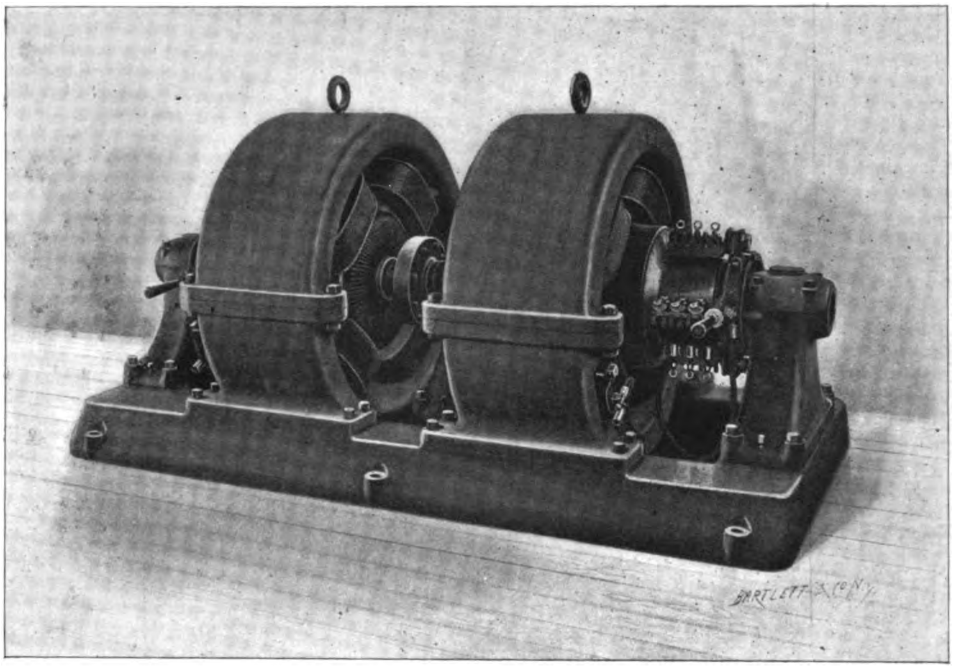

FIG. 17.—100 HORSE-POWER "BOOSTER" FOR RAIL WELDING.

IX.

Before passing on to a brief notice of a few of the direct-driven appliances and the generating apparatus built by the Crocker-Wheeler Company, it may be well to note, even at the risk of tiresome iteration, the principle upon which their applications of electric power are based and upon which they are now rearing one of the standard electrical industries of the country. The electrical reader of this journal is familiar, doubtless, with the proposition, but that it still needs lots of missionary work is evidenced by the literature recently issued by one of the foremost engineering concerns in the country, offering its services in special installations of long rope drives for power transmission in mills and factories. The very cuts they use are calculated to make an electrical power engineer rub his eyes in astonishment and wonder whether this famous house may not have been indulging in a Rip Van Winkle sleep.

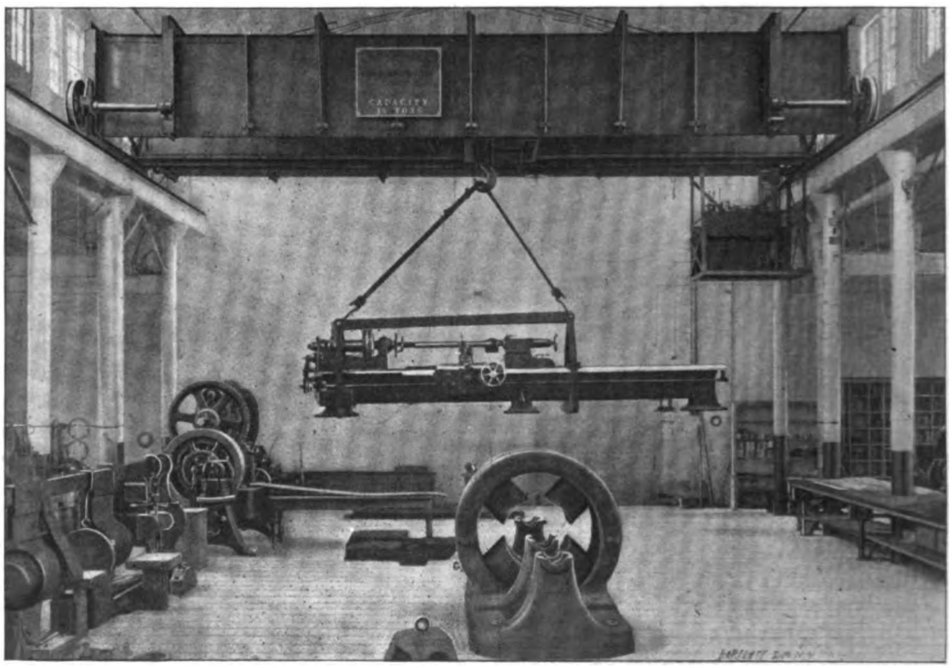

FIG. 18.—ELECTRIC ENGINE LATHE IN OPERATION WHILE SWINGING FROM CRANE.

The ideal condition of electrical power transmission is, of course, that each machine should embody and receive its own motive power. This being done through the co-operation and interchange of plans by motor builder and tool builder, it is at once seen that the cost of mill construction may be lessened, as the heavy strains of shafts and belts at certain points are taken away. Then comes the factor of greater cleanliness and light, while in many trades the absence of the static electricity which has been caused by the friction of belts, etc., is a decided boon. Beyond this, lies the smallness of the power plant necessary, only the exact power needed being taken at each moment, resolving itself into a figure far below that of a factory power plant of the old type. Another point is the ability given at once to utilize water powers within a range of several miles and often in regions where coal and wood are very dear. Yet again comes the point that the power when delivered at the tool is used up under the best conditions. It is said that the chief duty of the machine tool is to remove superflous metal, and that one horse-power will slice off 40 lbs. of cast iron, 33 lbs. of wrought iron, and 23 lbs. of steel. Now, if in almost any fair sized group of shops taken the lost work ranges in the vicinity of an average of 60 per cent., it will be seen that a system which permits the immediate application of the power and an instantaneous stoppage of it, has claims on the score of economy that no manufacturer can ignore. Yet another favorable condition is the fact that the new method permits compactness, which means the requirement of less floor space and less real estate for a given output, and this again brings in the further point that motor driving has everywhere been found to result in smoother operation, with more uniformity in the goods and the ability to secure a better price for the higher quality.

As to the saving in power effected, the diagrams here shown are proof of what can be done. The two upper diagrams are plotted from indicator card readings taken every fifteen minutes during a day's run at the factory of the Central Stamping Company, in Brooklyn. The power required to run the shafting, belting, etc., without tools, was taken in the mornings after the engine had started and before the day's work had begun. At noon and night the same conditions applied. Slightly more power was needed in running in the morning, after the shaft-

ing had been at rest, than at noon when it had been running some time and when the static friction had therefore been

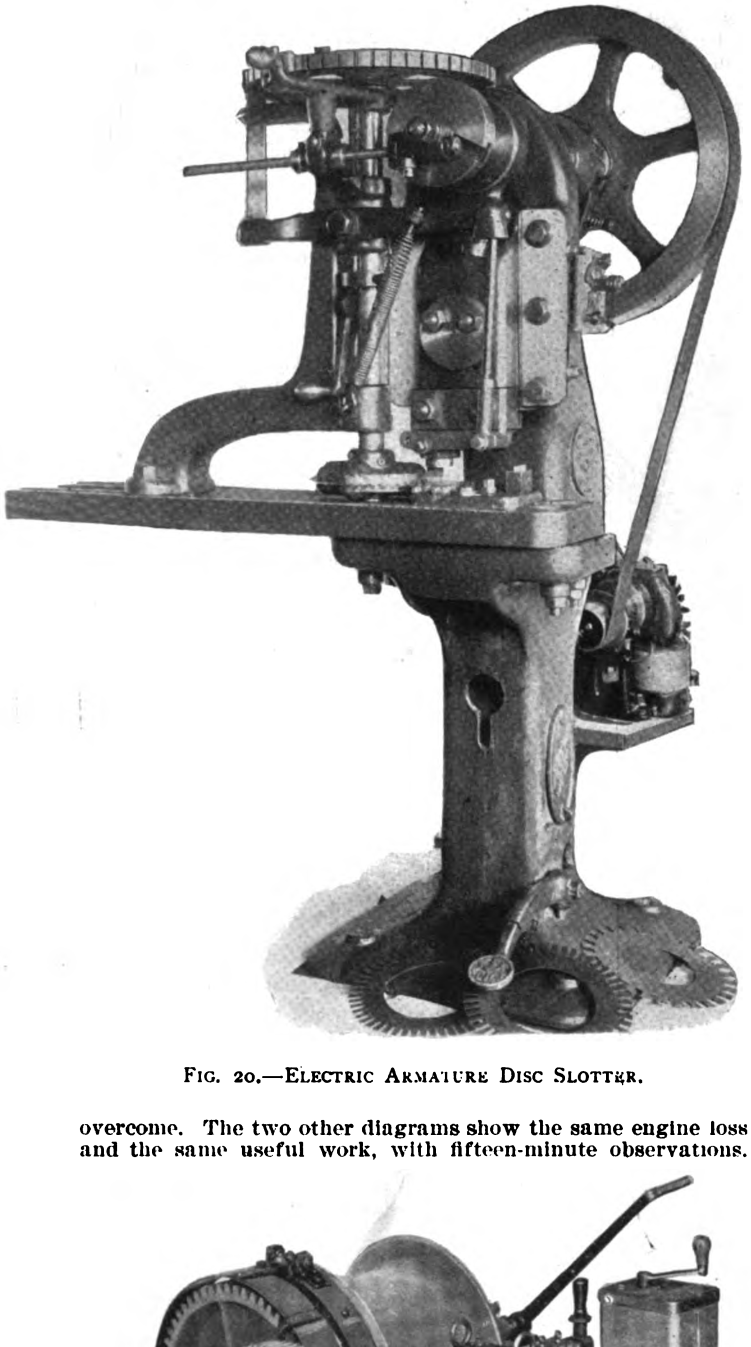

FIG. 20.—ELECTRIC ARMATURE DISC SLOTTER.

overcome. The two other diagrams show the same engine loss and the same useful work, with fifteen-minute observations.

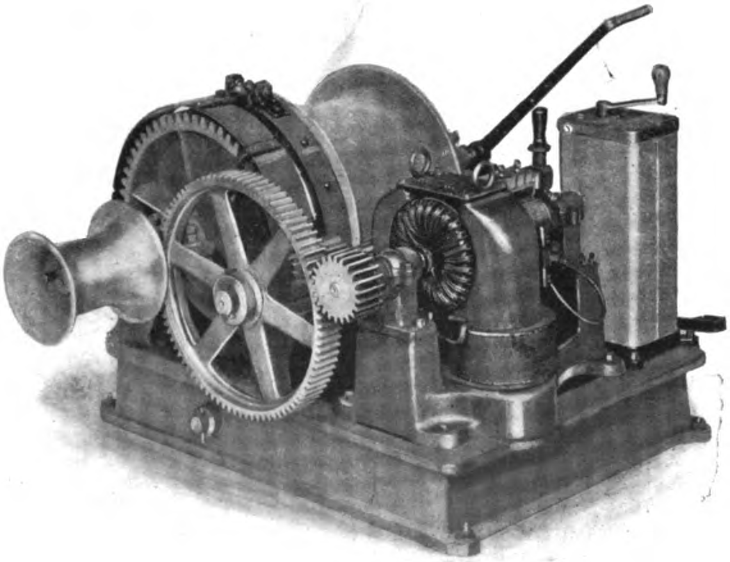

FIG. 21.—ELECTRIC DOCK HOIST.

As an offset to the losses in the friction of shafting are inserted the constant losses which would occur in a dynamo equal to such a plant, as well as those which would occur in motors and in the wires supplying them when delivering the amount of work called for by that part of the diagram included under the designation of "useful work." The assumption of variable losses in the motor and line at 30 per cent. of the useful work is obviously fair and reasonable, and one sees at a glance the relative economy of the two methods, and the saving effected by the electricity.

X.

The works are full of tools and machines that exemplify the belief of the company in their own doctrines and furnish remarkable proof of the manner in which the motor can become an integral part of the mechanism to be driven. A number of the tools are here illustrated, while a few preliminary cuts are shown illustrative of the electrical details of the apparatus.

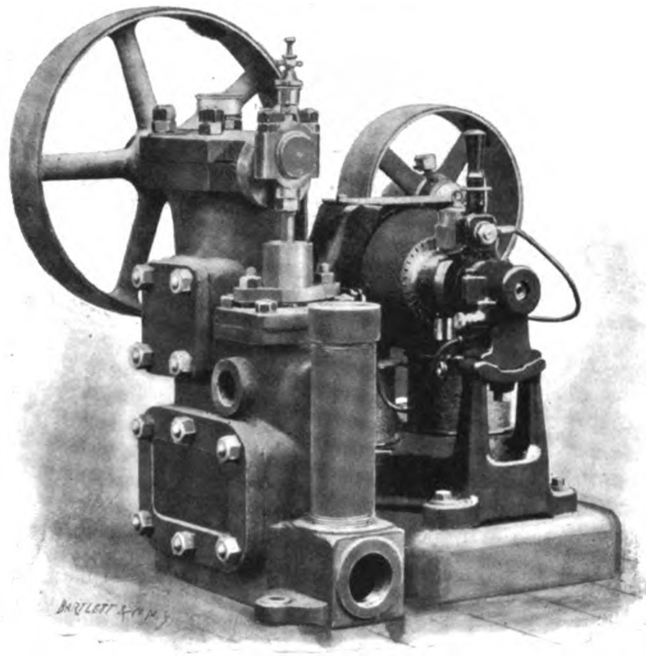

FIG. 22.—BELTED ELECTRIC HOUSE PUMP.

Fig. 5 shows men engaged in winding a 100 kilowatt direct connected armature, and Fig. 6 shows the same complete. Fig. 7 is a view of a 50 kilowatt generator complete direct connected to the engine on the same bedplate. The brushes are supported by a new style of rocker arm, which also carries the current. Consequently the brush studs are metallically connected to the supporting parts, instead of being as usual fitted with insulating bushings that intervene. The brushes are all lifted by a little hand lever at the top. They are controlled by a series of connected links and the links are provided with insulating joints. The adjustment of the point of commutation is made by rotating the rings supported at the extremities of the three stationary brackets reaching out from the field frame, on which they travel on rollers. Figs. 8 and 9 illustrate some of the Crocker-Wheeler direct-connected outfits of four kilowatt and seven kilowatt capacity. Fig. 10 shows their 225 horse-power generator, which output it gives at 400 revolutions. The weight is fifteen tons. Its outboard bearings give firm support to the large pulley. The entire lower half of the machine with the three bearings complete is one piece of iron, giving great rigidity and the steel pole pieces are also cast into the iron.

Fig. 11 is the 100 horse-power machine. Its weight is six tons. The one shown has its brushes arranged for alternating current work. Fig. 12 is the armature core of a 40 horse-power machine before winding and shows the method of clamping the laminae on the shaft. Fig. 13 shows the armature when the "envelopment" is complete. Fig. 14 is an armature of the same size, but with slots for the reception of bar winding. It shows a view of two sets of the bars and the connectors at the end of the armature in position. It is intended for a multipolar two-circuit winding, made under the Bradley patents.

Fig. 15 is a 10 horse-power automatic brake motor with countershaft through the base and changeable gears, giving two speeds to the countershaft. The brake band is attached to one of the field magnets which moves slightly in response to the current and causes the band to grasp the armature or release it, as the current is thrown on or off. Fig. 16 is a 15 horse-power motor with a countershaft through the pedestals, and is

single reduction, intended for mill work. Fig. 17 is a booster consisting of two 100 horse-power machines mounted on a special bedplate. The weight of this massive and useful unit is eleven and a half tons. Fig. 18 gives a view of the crane in the works, to which special reference has already been made.

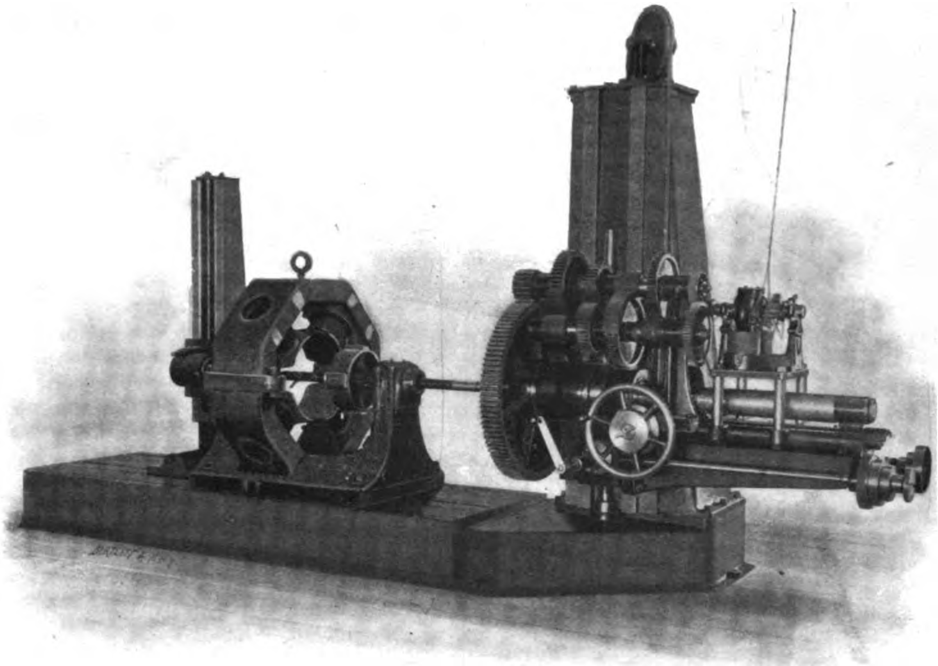

FIG. 19.—MOTOR BUILT ON BORING HEAD, SUPPLYING POWER TO 10-TON BORING MILL.

Fig. 19 is a large boring mill, the weight of which is ten tons. It is driven by a one horse-power motor, the current for which is supplied through an ordinary lamp cord. The adjustments of the machine require the boring head to slide up and down on the column. This necessitated a vertical shaft the height of the housing, with means for keeping it in constant connection with the gearing of the boring head in whatever position the latter might be. The introduction of the motor not only did away with the shaft and bevel gears, but with countershaft and saved all the power that was consumed in operating that transmission in which there was obviously a large amount of friction.

Fig. 20 is a notching press specially designed for the Crocker-Wheeler Company, by the Ferracute Machine Company, to enable them to get out some of their special experimental appliances. It is driven by a one-half horse-power motor directly attached. Fig. 21 is an ordinary electric dock hoist, with the controller mounted on the machine. Fig. 22 is the latest form of Worthington electric house service pump, with a one horse-power motor. Fig. 23 shows a 75 horse-power motor incorporated into a very heavy Worthington steeple pump, such as would run a fair sized city plant.

XI.

We come now to another very interesting batch of Crocker-Wheeler apparatus. Fig. 24 is a Bement & Miles hydraulic press of the pattern usually built for forcing car wheels on axles. In this instance it is specially arranged to be electrically driven, and a capacity of 150 tons pressure is obtainable. Fig. 25 is a Ferracute punch press with motor supported on a bracket on the back in such a position as to gear directly into the teeth cut upon the face of the ordinary fly-wheel of the press. It is a pretty and ingenious rig.

Fig. 26 shows two sizes of controllers or regulators for motors on heavy power work. The contacts are all made of heavy castings and are easily replaceable. Each contact is arranged to be out of the range of the others, so that in case of any trouble, the burning out of one will not interfere with the perfect action of the rest.

Fig. 26 A shows a 1-6 horse-power motor-dynamo for charging storage batteries for telephone exchanges, by current direct from the lighting circuits of the building. The machine is provided with a circuit-breaking device operated by the fields of the machine, so that the battery is automatically disconnected when the machine stops.

Fig. 27 is a universal adjustable boring mill built by the Newark Machine Tool Company for fine work, and fine work it does. This was originally operated by cones and belts, but has been altered by the substitution of a cone of gear wheels in place of the belt pulley, to which a bracket supported motor is geared. The usual changes of speed are therefore obtained by throwing either one or the other of the set of gears in the cone in action.

Fig. 28 is a small punch press with motor mounted on a side bracket and connected by a belt which passes around an "outboard idler." By this arrangement a very large circumference of contact is secured on the motor pulley, enabling the machine to be operated by a smaller motor and pulley than would otherwise be the case. Fig. 29 is a Bridgeport vertical boring mill, which was driven by cone and belt and altered by the Crocker-Wheeler Company after purchase, by adding a cone of gears to which the motor is attached. Changes of speed are obtained by the shafting feather which engages one or other of the gears. Fig. 30 is a novel piece of machinery to find in an electrical works and is a regular silk loom on which a one horse-power motor has been attached. Six of these were set up in operation at the old works, up to the time of the fire, turning out choice samples by which the salesmen of the Ampere Silk Company were enabled to take their fall orders while the mill of the silk company was being built. The driving of looms has always been considered as requiring the highest attainable smoothness in power work.

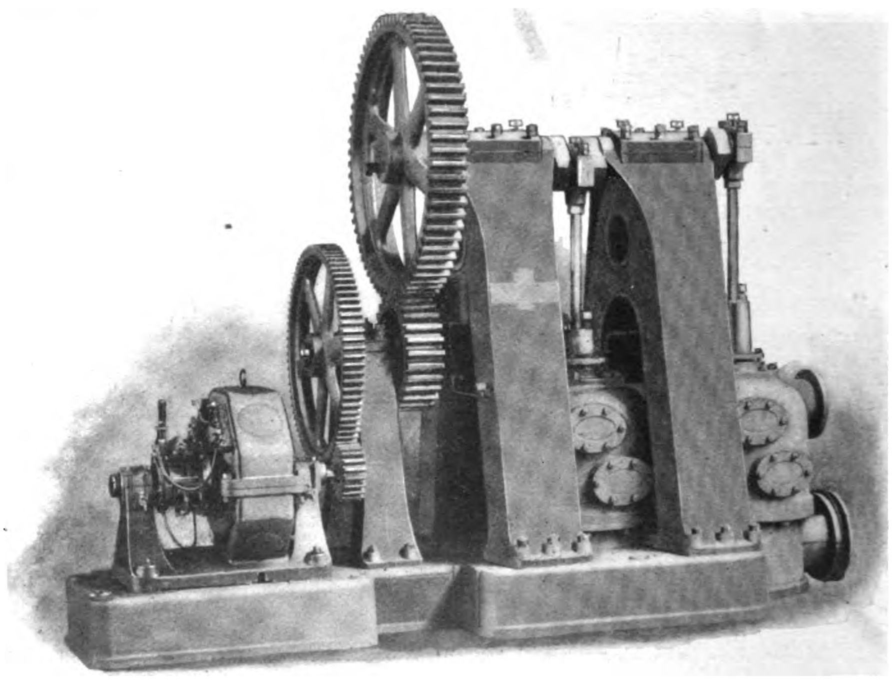

FIG. 23.—MOTOR GEARED TO "STEEPLE" PUMP.

XII.

A high grade of product cannot be obtained without a high grade of men, and from the start it has been the desire of Dr.

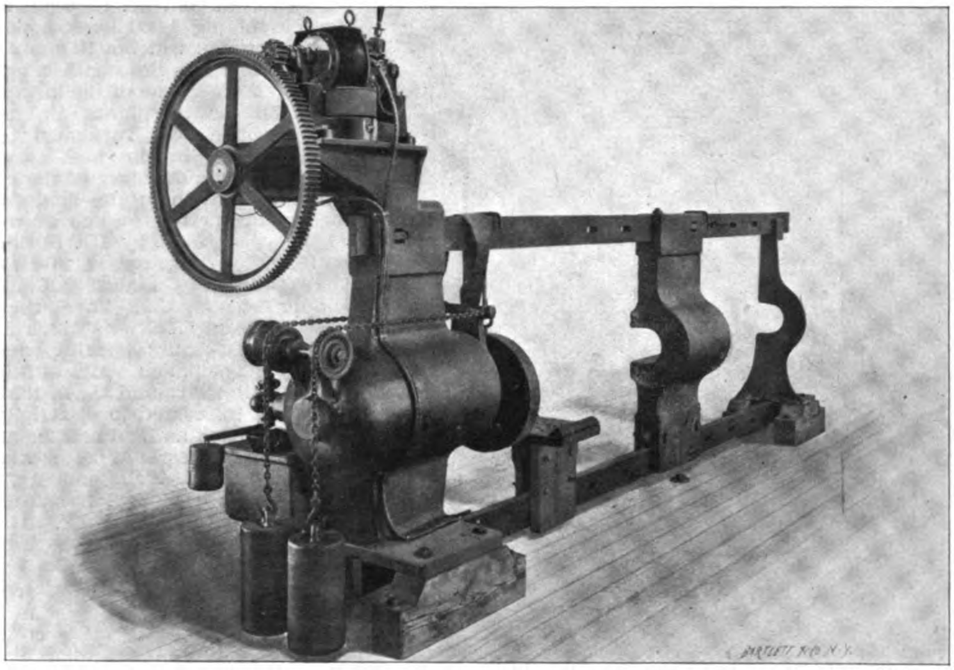

FIG. 24.—ELECTRO HYDRAULIC PRESS, 150 TONS CAPACITY.

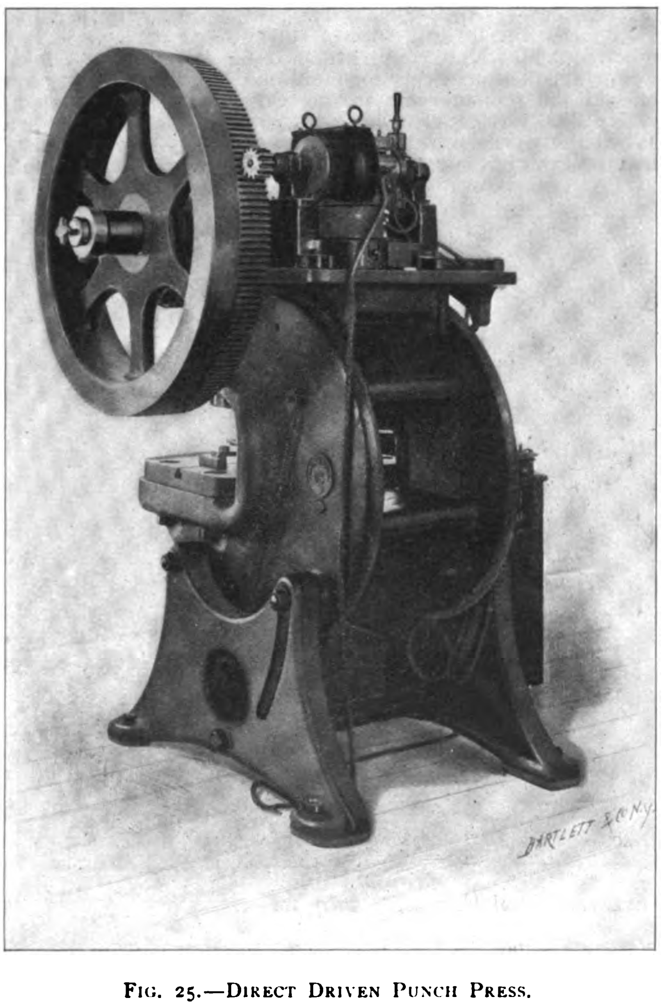

FIG. 25.—DIRECT DRIVEN PUNCH PRESS.

Wheeler and Professor Crocker to surround themselves with a staff of the highest creative and executive ability. It is telling the simple truth to say that in their efforts they have been successful and have gathered around them a corps, each member of which is a picked man and known for his leadership and force. This article would not be complete without brief personal note and biographical data of the men who have carried the Crocker-Wheeler Electric Company to the front rank and who keep it there.

Schuyler Skaats Wheeler, president of the Crocker-Wheeler Company, was born in New York City, in 1860, attended the Friends' Seminary, Keble Hall, Columbia Grammar School and Columbia College. Leaving the college in 1881, Mr. Wheeler became assistant electrician of the Jablochkoff Electric Light Company. When that company dissolved he joined the United States Electric Lighting Company, and subsequently left them to become a member of Mr. Edison's staff. Mr. Wheeler was present at the inauguration of the Pearl street station, was afterwards made the electrician in charge, and was detailed to lay the underground systems in other cities. He then became superintendent of the Newburg (N. Y.) Edison Company, resigning that post to accept the position of electrician to the Herzog Teleseme Company. Mr. Wheeler left the latter company at the time of the organization of the C. & C. Electric Motor Company, which he joined as electrician and factory manager. After establishing the factory of the C. & C. Electric Motor Company, he organized the firm of Crocker & Wheeler, electrical engineers, which was shortly afterwards incorporated as the Crocker-Wheeler

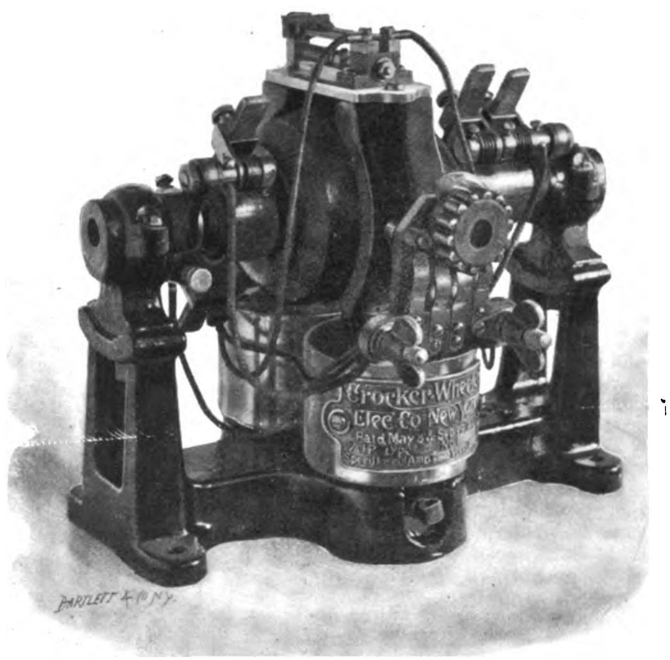

FIG. 26A.—1/6 HORSE-POWER DYNAMOTOR, WITH AUTOMATIC CUT-OFF SWITCH.

Motor Company, of New York State, and afterward the Crocker-Wheeler Electric Company, of New Jersey, of both of which he is the president. He was also appointed electrical expert of the Board of Electrical Control of New York, holding this position about seven years, or from the time of its creation to its abolition, doing much in relation to overhead wires in New York, and becoming very prominent before the public. He is also president of the Bradley Electric Power Com-

pany and a director in the important American Electric Heating Corporation, of Boston.

He is the author of numerous writings on electrical matters, including two illustrated supplements to "Harper's Weekly," in 1888 and 1889, upon "Applications of Electricity," and upon "Electric Lighting," and is joint author with Professor F. B. Crocker, of "The Practical Management of Dynamos and Motors." He has received the honorary degree of Doctor of Science on account of his electrical work and writings during a period of about four years after leaving college. He is a member of the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, the University Club, Chamber of Commerce, the American Yacht Club, the Uptown Association, etc.

Professor Francis Bacon Crocker, vice-president of the company, is a member of an old New York family and a graduate of Columbia College School of Mines. His early work in the motor field has already been referred to. When the question came up of inaugurating special electrical studies at Columbia, he was one of the two or three men hit upon for selection, and the choice that was made has proved to be very happy. The electrical work done at Columbia is of high order and value. Outside his engineering and professional work, Professor Crocker has been a prolific writer, and his new book on the subject of power plants and electric lighting is easily one of the standards. He has also been very active in the work of the American Institute of Electrical Engineers, and is regarded as one of its foremost members and officers, as well as one of its most useful and faithful. He is a member of the University and other Clubs, but confines his energies within well-marked channels of educational and professional activity.

Harvey Lamb Lufkin, manager of the company, is one of the very few whose time has been continuously devoted to the development of the electric power industry from the practical standpoint since the first advent of the commercial electric motor. To Mr. Lufkin's early conceptions of the possibilities of electric power as applied in mills and factories and his persistent industry in enforcing his beliefs, is due in a large degree the growth of this branch. At the time of his association with this company in November, 1892, its product was confined to motors and dynamos of 5 horse-power and under. That a recent contract for a power plant involving 1,000 horse-power of apparatus in which a 100 horse-power motor was the smallest machine, and that some of the largest industrial power plants in the country have been furnished by this company in the past three years, is strong evidence of the remarkable growth of the business during this period. Some of the original work done by Mr. Lufkin in the field of applied electric power embraces almost all the leading events that have their place in history fully as much as the landmarks of lighting and railway development. Mr. Lufkin was born in Cleveland O., in 1857, was early interested in electricity and as far back as 1886 became an associate of Messrs. Wheeler and Crocker in the C. & C. Company.

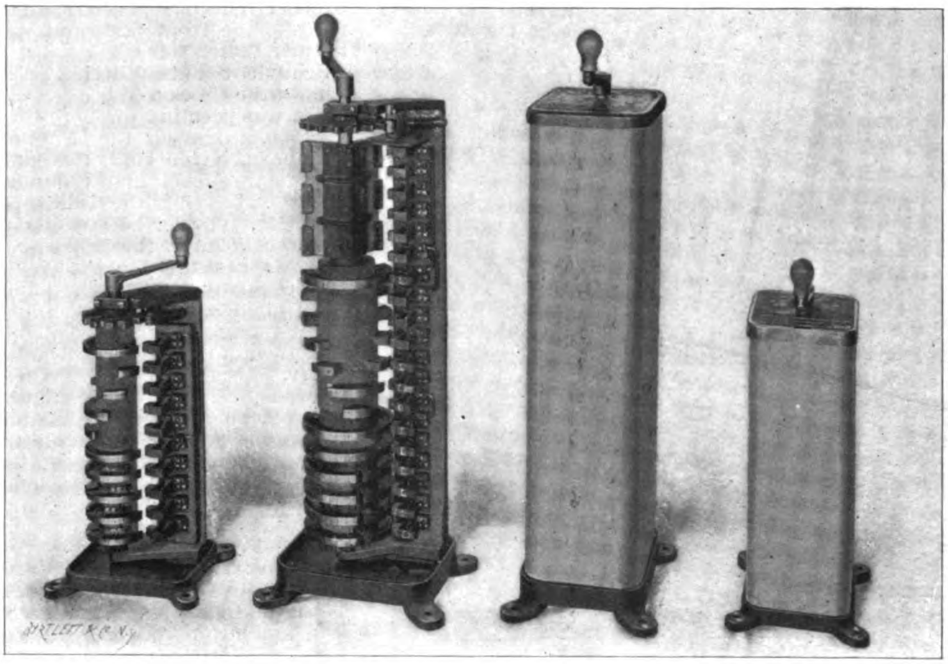

FIG. 26.—REVERSING REGULATORS FOR HEAVY MOTORS.

Frank Moore Jeffery, treasurer, was born in Corning, N. Y. His early life was spent at New Haven, Conn., and Oxford, Md. Removing to Jersey City, N. J., he established a printing business which was transferred to 22 Beekman street and carried on under the firm name of Jeffery & Johnson. He withdrew from the firm to engage in the manufacture of springs and in 1888 he formed a partnership with his brother, D. H. Jeffery, for the manufacture of springs and wire work, large quantities of which were furnished for the Crocker-Wheeler Company. Through this acquaintance, Mr. D. H. Jeffery was offered the treasurership of the Crocker-Wheeler Company, which finally resulted in his withdrawal from the other firm. When the works were removed the Company reorganized under the laws of New Jersey, and F. M. Jeffery became one of the charter members. Since that time he has been its resident director. Shortly after this arrangement was made, Mr. D. H. Jeffery died very suddenly and Mr. F. M. Jeffery was elected secretary and treasurer in his place. Besides attending to the finances, Mr. Jeffery has the general management of the

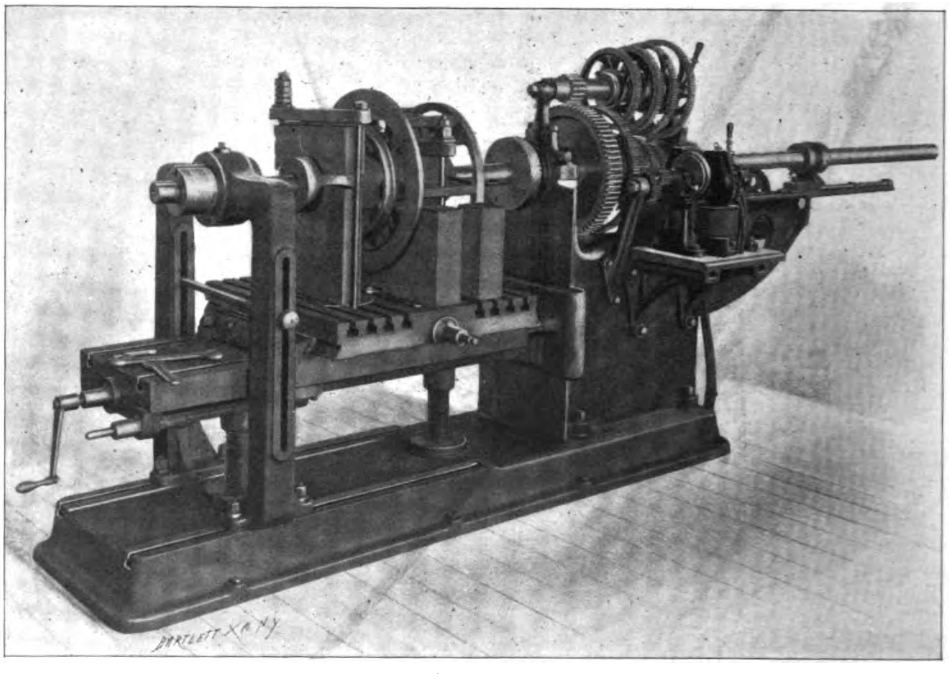

FIG. 27.—ELECTRIC BORING MILL FOR FINE WORK.

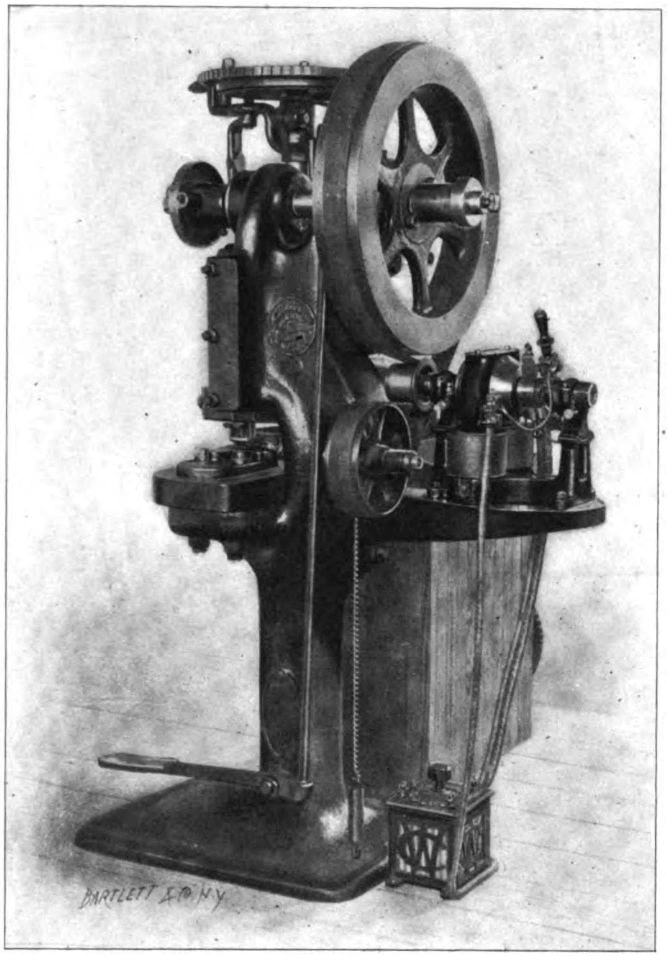

FIG. 28.—ARMATURE NOTCHING PRESS, BELT DRIVEN.

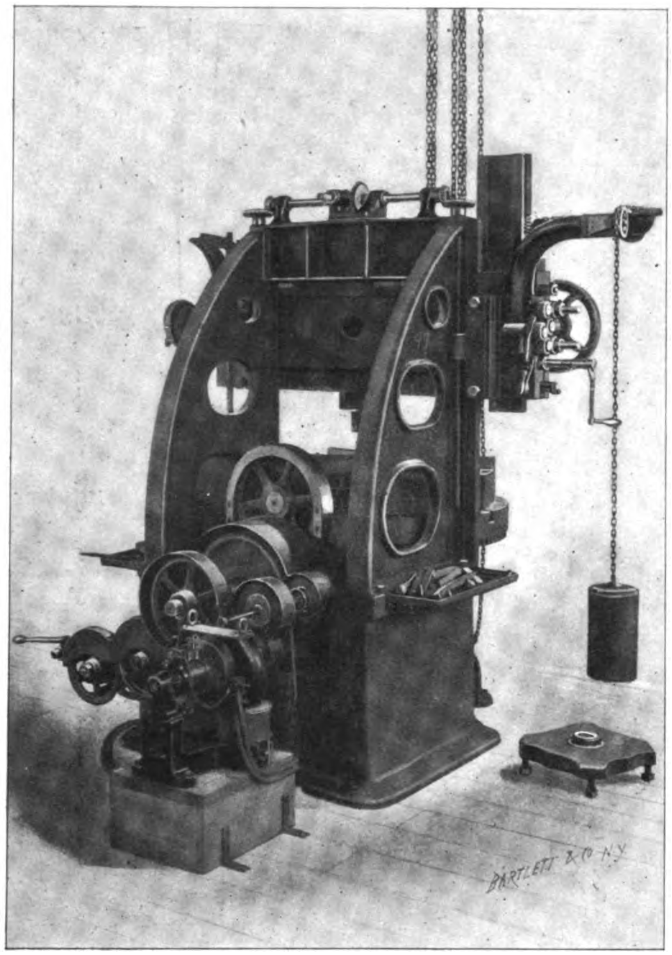

FIG. 29.—VERTICAL BORING MILL, DIRECT GEARED.

works. His thoughtful and systematic attention to production has contributed largely to the success of the company. The treasurer is ably assisted at the New York office by George W. Bower, cashier and general bookkeeper, whose accuracy and faithfulness are unfailing.

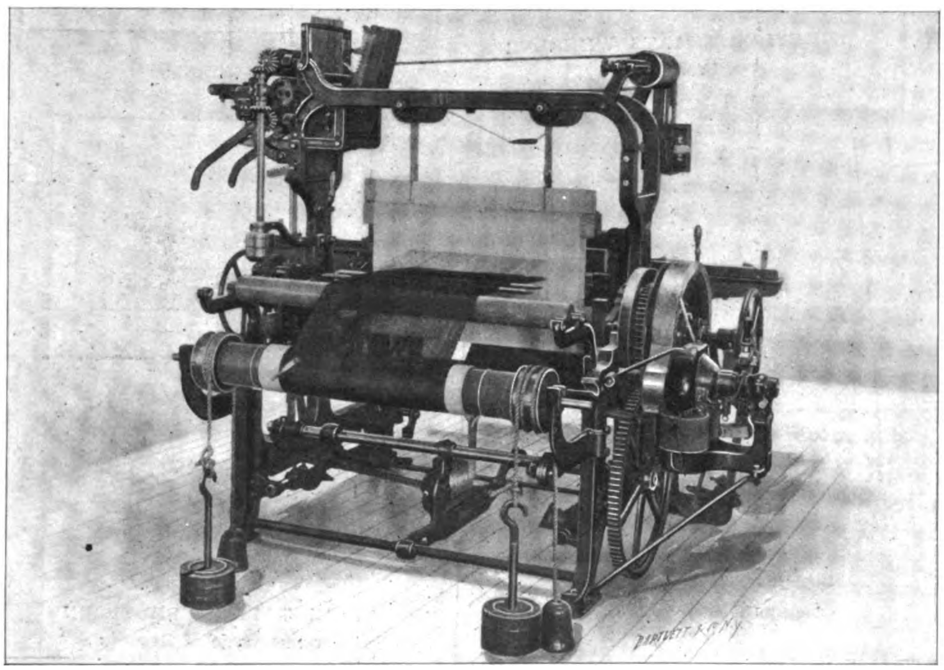

FIG. 30.—ELECTRIC LOOM WEAVING AMPERE FIGURED SILK.

Gano Sillick Dunn, chief engineer of the company, was born in New York and graduated from the City College in 1889 with the degree of Bachelor of Science; thence entering the new post graduate course in Columbia College immediately, from which he graduated in 1891 with the degree of Electrical Engineer. Although on account of reverses Mr. Dunn supported himself entirely by outside work as a telegraph operator during his entire courses at both colleges, he ranked close to the head of his classes and was an honor man and a member of the Phi Beta Kappa.

Immediately after graduation in June, 1891, he went to the Crocker-Wheeler factory for one week for experimental work, with such commendable results that he was never allowed to leave. As electrical engineer and as chief engineer, Mr. Dunn is the responsible head of all the engineering work.

His new designs are models of modern engineering skill as shown by the reputation of Crocker-Wheeler apparatus to which he has also contributed many valuable inventions.

He is a member of the American Institute of Electrical Engineers and vice-president of the New York Electrical Society. Mr. Mr. Dunn's lectures have brought him into considerable prominence, his last lecture on Dynamo and Motor Design having been greatly in demand in pamphlet form.

Miss Belle Jeannette Hamilton, the order clerk, though born in New York, is of Scottish descent on both sides. She entered the service of the company as stenographer in June,

OFFICERS AND STAFF
THE CROCKER-WHEELER ELECTRIC CO.

1890, since which time she has risen to the highest clerical and confidential position in the company. Stationed in the New York office, she has sole charge of the entry of every order on the works. The interpretation of orders and the figuring of many electrical questions, for which she has fitted herself by private study, is done in a way that surprises many engineers, and is of great credit to her. Miss Hamilton acts also as confidential clerk to the directors.

Frederick Malling Pedersen, M. S., E. E., is engineer in charge of specifications and records. Mr. Pedersen is a graduate of the College of the City of New York, and received the degree of Bachelor of Science in 1889, of which class he was valedictorian. He then taught manual training for one year and studied architecture. He received the degrees of Master of Science from the College of the City of New York in 1893 and of Electrical Engineer from Columbia University in the same year. He joined the Crocker-Wheeler Electric Company immediately after the completion of his electrical course. Since then he has delivered frequent lectures before the Pratt Institute, the Young Men's Christian Association, the American Institute and the Henry Club.

August Hartmann, superintendent, was born in Hanover, Germany, in 1849. He received his early education in the gymnasium, and entered Wellenkamp's machine shop at the age of 14, where he served his time. He came to America in 1867, and entered the Singer Co.'s factory in New York City. After remaining there five years he went with the Caligraph Company, and then the Columbia Typewriter Company. In 1886 he entered the employ of the C. & C. Motor Company, in New York, under the management of Dr. Wheeler, and upon the organization of the Crocker-Wheeler Electric Company he left them to take the position of foreman and afterward superintendent of the Crocker-Wheeler Company's factory, which position he has occupied continuously to the present time, covering a period of seven years and extending through their occupancy of the factories in Twenty-eighth street and Fourteenth street, New York, their removal to Ampere and their recent successful struggle to overcome the effects of the fire.

Arthur Lispenard Doremus, a valuable assistant to Mr. Lufkin, in the New York office, is the son of the distinguished scientist and chemist, Dr. R. Ogden Doremus. He was born in New York City in 1869, and attended the College of the City of New York until 1892. Since that time he has been engaged in the service of the Crocker-Wheeler Company.

Henry Chase Ware, factory office manager, was born in Cumberland County, New Jersey, in 1857. His education was received in the public schools. At the age of 21 he entered the employ of the Ferracute Machine Company, of Bridgeton, N. J., in whose service he remained for nine years, as stenographer and bookkeeper. In 1888 he came to New York to take the position of private secretary to the president of the Pittsburg, Shenango and Lake Erie Railroad Company. In the latter part of 1889, he entered the New York office of the Edison Machine Works (afterward consolidated with the General Electric Company, as confidential stenographer and accountant, and for more than four years he was connected with the various branches of the Edison business, a portion of which time was spent at the factory of the Edison Phonograph Works, Orange, N. J., in the capacity of business manager. In the latter part of 1894, Mr. Ware engaged with the Crocker-Wheeler Electric Company, assuming charge of their factory office, time and cost accounts, the purchasing of factory supplies and the correspondence relating to the same.

NEWS AND NOTES.

LORD KELVIN'S JUBILEE.

The celebration of Lord Kelvin's jubilee began at Glasgow on Monday evening, with a conversazione at the Glasgow University. Attendants from many foreign countries were present and the crowds attending the celebration were enormous. Congratulatory telegrams were received from all over the world. Lord Kelvin replied to these by a dispatch sent around the world and returned to the University in four minutes. In New York the event was celebrated by a reception given by the Commercial Cable Company in their offices in the Postal-Telegraph Building. The guests were welcomed by Mr. John W. Mackay and Mr. George Clapperton proposed the health of Lord Kelvin in a very felicitous toast, reciting Lord Kelvin's achievements.

Among those present were Mr. N. Tesla, Professor E. J. Houston, Mr. F. J. Sprague, and other members of the electrical profession and press.

In response to the congratulatory telegrams sent by many of those present, Lord Kelvin replied as follows:

"To my Friends at New York.

"Thank you warmly for your kind sympathy with me on the occasion of the jubilee. I wish I were near enough to shake you every one by the hand and to tell you how much gratified I am that you think of me as a friend and comrade.

"KELVIN.

"Glasgow University, June 15, 1896."

THE TELEPHONE AT THE ST. LOUIS CONVENTION.

At the Republican National Convention, to be held in St. Louis, there is one innovation which will attract attention. In order that the various delegations may at all times be in close touch with the chair, telephonic communication will be provided. Thus, when a delegate in any part of the hall secures the floor, his name is made known to the chairman by means of the telphone, and he will be promptly recognized. In the same manner a delegate may be promptly informed of the question before the house at any time such information is needed. In fact, the telephone may be used in many different ways, and it is believed that it will be found such a great convenience that hereafter the system will be adopted in all great conventions.

A TARGET-SEEKING TORPEDO.

A magnetic attachment has been invented by Mr. C. D. Hawkins, of Boston, the object of which is to draw the torpedo toward the iron armor of a ship against which it is to be projected. In a preliminary test by the Bureau of Ordnance, the wind blew forty miles an hour, and the sea was very rough, but torpedoes fitted with the target-seeking device made more than thirty miles an hour. The government has a contract with the inventor to dispose of the device only to the United States if it proves successful.

JAPANESE ACCURACY.

It is stated that the Japanese are very exact in their tests of goods made under contract, expecting even large pieces of machinery to be mathematically true in every particular. In one instance 450 tons out of 700 tons of galvanized iron telegraph wire imported from Germany were rejected because they had become very slightly oxidized in places when on board ship, and in another again a further quantity of telegraph wire was rejected because its diameter was found to be three-thousandths of an inch too large. This exactitude has its good side, however.

PRIVATE ELECTRIC ELEVATORS IN NEW YORK.

The New York "World" gives a list of about thirty-five private houses in New York City where electric elevators are in use. The names given are those of the leaders of the city's wealthy and fashionable circles, but there is no reason why people of lesser degree should not enjoy the same boon.

TEN THOUSAND DOLLARS is the neat sum that 1,278 employés of the Brooklyn Heights Railroad Company are to have distributed among them as the reward of care and good behavior during the winter.

LETTERS TO THE EDITOR.

MOUNTINGS FOR FLUOROSCOPES.

IN answer to Prof. O'Reilly's good-humored attack on my visual powers, I would assert that I have recently been making a study of optical illusions and I have yet to learn that the dilation of the pupil is able to cause the irregular illumination of the screen referred to; but, granting, for the sake of argument, that the dilation is the cause of the apparent irregularity, then, the eye being at fault, all screens tried at any one time must show the same fault. But such is not the case, therefore the screen and not my sight is at fault.

Since examining the sample the report on which called forth the above argument, I have had opportunity of examining another aluminum fluoroscope of Mr. Le Roy's make and found that it had, unlike the first sample, a uniformly bright screen, but the brightness of its screen was still decidedly inferior to that in Aylsworth & Jackson's instrument.

My tests were made with care and in an entirely disinterested manner, and I can only confirm my first report.

HENRY V. PARSELL, JR.

New York, June 9, 1896.

CONTENTS.

BROOKLYN TROLLEY ACCIDENTS.

THE City of Brooklyn has had, perhaps, more fatalities than any city where the trolley system has been introduced, but most, if not all, of these accidents previous to that of last week have been due to the carelessness of individuals or the running of cars at too high a speed, but the runaway of the car on the Nassau Electric Railway Company's tracks appears to be among that type of accidents due rather to faulty apparatus and carelessness on the part of the conductor, than the negligence of the motorman. There is probably necessity for more care in running the cars in certain parts of Brooklyn than in almost any other locality, as the tracks from numerous directions converge to several centers where travel is extremely congested. At these points, during certain hours, both pedestrians and motormen can only avoid accidents by the use of extreme caution, and the running over of a number of people at such places is partly explained, and to some extent excused, by the conditions of travel. The accident to which we specially allude, the running away of a car backwards on a down grade, is not of a kind for which it is easy or desirable to find any excuse. From every account which has been published it seems apparent that the motorman was far less to blame than the conductor and the equipment of the car, for which the company is responsible. In the first place, the car was crowded far beyond the limit of safety, and it certainly comes very close to criminal negligence to permit 133 passengers to ride on a car that was built to carry 50 people. When a car is overcrowded in this way it almost always happens that most of the crowd is concentrated near the rear of the car. This takes the weight off the front wheels so that even if they are stopped by the brake it has but a small effect on stopping the car if the grade is considerable.

The use of heavy cars of extra length, which are run at the rate of fifteen miles an hour, or more, at some points of the road, is entirely incompatible with the use of hand brakes of any description, and they are particularly inadequate in the case where heavy grades are to be encountered. Apparently, the company realized this fact as it had adopted the primitive method of stationing two men at the dangerous grade armed with planks to throw under the wheels of runaway cars! What is really needed in this case is a power brake. As a matter of fact, the brakes on trolley cars in general have never kept pace with the requirements of the latter. While the weight and speed of trolley cars are greatly in excess of that of any horse car, the same brakes are frequently used indifferently on both cars, the extra power necessary for the trolley car being supplied by the motorman. On a road where heavy grades occur, emergency brakes of some kind are almost indispensable, and emergency brakes should be applied to the car in such a way that both they and the ordinary hand brakes co-operate independently. This precaution is required in case of the disablement of either one, as was the case in the accident above alluded to.

Another safeguard which should be always held in view by the motorman, especially at dangerous points, is the reversing of the direction of the motors, or rather, as in the present case where the car was running away backwards, running the motors so as to drive the car in a direction opposite to that in which it is going. This last resort was ineffective in this case on account of the slipping of the trolley from the trolley wire. This, of course, was the primary cause of the accident in question, which could have been speedily averted by replacing the trolley; and it appears to have been gross carelessness on the part of the conductor to leave his post at the rear of the car at such a dangerous point of the road. If the trolley had been replaced no accident could have occured even if the brake had been perfectly useless. The importance of having the trolley in proper condition and always in connection with the line cannot be overestimated, and in this respect a large proportion of the trolleys in Brooklyn are decidedly at fault.

Their location under the elevated railroad structure submits them to very hard usage whenever they slip from the line, and many of the cars running on these lines carry trolleys which are badly battered and bent. In the present case complaint had been made about the frequent slipping off of the trolley, but the car was continued in service in spite of this defect. On a level road this would not usually be a source of danger, but on a grade it may easily be the cause of a serious accident as in the present case.

As nearly as can be learned, this accident was due to overcrowding the car, the absence of sufficient braking facilities and the failure to replace the trolley upon the line as soon as it had slipped. The accident cannot therefore be laid to any inherent defect of the trolley system, but entirely to the improper management and equipment of the road and the carelessness of the employés on the car. The lessons taught by it will, it is hoped, not be lost.

STATION SAFETY DEVICES.

ELECTRICAL distribution has called into life numerous auxiliary devices, but though considerable time has lapsed since some of these were first brought out, not all of them have by any means reached a final form, let alone a general standard such as we find in some of the older arts, as, for example, in gas lighting. Take the case of incandescent lamp sockets. The number of types of these still in general use requires manufacturers to keep on hand stocks to meet the demands of their customers, such as cannot probably be found in any other trade of like nature. True, the question has been agitated quite recently looking toward a unification which will bring about a standard form of socket, but the many conflicting interests involved seem to indicate that the day of its adoption is still far in the future.

Another, and in some respects perhaps even more important adjunct to electrical distribution on which difference of opinion still exists to a marked degree, is the question of safety devices. As experience accumulates the impression among electrical engineers becomes stronger and stronger, that the fusible cut-out embodies defects which render it unsuitable for much of the work to which it is now applied, and the result has been that for the more important uses to which a safety device of this nature is requisite, the magnetic cut-out or circuit breaker is alone suitable. This, of course, applies more particularly to central station work and a visit to the most modern power houses shows a marked absence of fuses. But there is one aspect of the question in connection with central station safety appliances which has perhaps not been discussed as fully as it might be, and which involves the startling proposition to remove all safety devices of whatever nature from all lines leading to the outside system of distribution. This proposition will probably be regarded by most central station managers as a rank heresy, but we know of at least one large central station distributing several thousand horse-power, both for lighting and power, in which not a single safety catch is connected to the distributing circuits! In justification of this revolutionary practice we are told that the station management considers it less onerous to run the risk of a burnt out armature than to incur the displeasure of customers by an interruption of the service. This practice has been in force for some time in the station mentioned, and we understand with satisfactory results; the only safety devices there employed being circuit breakers directly included in the dynamo circuits leading to the switchboard—and these are set to break at twice the normal capacity of the machines which they are designed to protect! It seems to us that this practice must at times put a very heavy strain on the system, both outside and inside the station, and practically nullify the advantage for which safety devices are designed. Yet, on the other hand, actual experience in the case mentioned appears to show that no baneful results have ensued from the practice and that indeed the balance seems to be in its favor. Of course, we believe that no one would advocate the slightest relaxation in the employment of protecting devices at the points of consumption of current, but in view of the above practical result, the question arises whether the matter of protection within the station may or may not be overdone in what is now considered best practice. We know that cut-outs constitute one of the bêtes noires of the central station manager, and just what is the limit of their usefulness is one of those matters which still constitute one of the open questions in the art.

A MODEL ELECTRICAL MANUFACTORY.

THE electrical industry has often been characterized as one of mushroom growth, and if this term be confined to the rapidity of its progress no one can find any objection to it. Yet, in spite of the rapidity of its rise, we know of none which stands on a more solid basis of actual work and achievement. Indeed, if the stability of an industry is to be gauged by the manufactories which it has called into existence, then certainly the electrical arts stand well abreast of any on which writers on modern industry are so wont to dwell.

The illustrated description of a modern electrical factory to which we devote extended space in this issue constitutes in itself a strong argument on the stability of the industry. Besides indicating the ability and enterprise of those to whom the creation of such an establishment is due, it exemplifies above all the rapid progress which is being made in the application of electric power to the direct driving of all types of machinery, with the consequent economy in power consumption. Machine tool builders of the more progressive type have long since realized and fallen in line with the inevitable drift towards this method of operation, but there are still many who shrink from undertaking what they consider a too radical step which the change to electricity involves; but it requires no great power of devination to foresee the time when the countershaft and belt in the machine shop or factory will be looked upon as a relic of barbarism. Electric power in machine shops means more than mere saving of coal under the boiler, however. It means more light, greater cleanliness, greater safety to the workmen and all those things that tend towards increased production and better quality of output.

LORD KELVIN'S JUBILEE.

IT is not often given to man to see the fruits of his thought and labor recognized and interwoven in nearly every department of science and industry; but such, indeed, is Lord Kelvin's happy lot. The celebration of the fiftieth anniversary of his professoriate at the Glasgow University is truly an event of universal importance. Whether we look upon his achievements from the scientific or the practical standpoint, everywhere we are confronted with that marvelous perception of the adaptability of natural laws to useful purposes, in which respect he stands without an equal. We join in the congratulations to Lord Kelvin, and in the wish for a long continuance of his life and labors.

CHARGING FOR ELECTRIC CURRENT.

AS was to be expected, the article by Mr. A. J. Farnsworth in a recent issue of The Electrical Engineer has served to call forth a contribution on the same subject in which the author does not entirely agree with Mr. Farnsworth on the practicability of the system of current charges proposed by the latter gentleman. Mr. Lewis seems to view the subject from the consumers' rather than from the central station standpoint and fails to see the commercial justice of asking the consumer to guarantee the fixed charges of the station, whether he does business with it or not. Apropos to the question under discussion is the system of charge adopted at Norwich, England, described on another page. Here the rate of charge between one hour before sunset and 8 p. m. is double that at any other time of the day, the meters being arranged to record in accordance with the rate of charge. We doubt whether a system so widely diverging in its rates could be successfully introduced in this country, but its adoption and evident good working abroad show to what extent consumers can be educated.

EXHIBITION NOTES—VI.

EXHIBIT OF THE ROOT IMPROVED STEAM BOILER.

OUR illustration gives a very good view of the exhibit made by the Abendroth & Root Manufacturing Company, of New York, of their famous improved Root water tube steam boiler, at the recent Electrical Exposition. These boilers were selected to furnish all the steam used at the exposition, the desire being to install a thoroughly reliable and model up-to-date boiler plant. This was the only working boiler plant shown and attracted a great deal of attention and favorable comment from visitors, who could not but be impressed with its cleanliness, efficiency and the ease with which it was managed.

There were two equal units forming one battery of 500 horsepower. A Wilkinson automatic stoker was used to distribute the coal upon the fire. The evaporative efficiency ranged from 10 to 11 lbs. of water per lb. of coal. The C. W. Hunt noiseless conveyor was used in delivering the coal and removing the ashes. So safe and simple was the entire operation of this plant that it was put in charge of Mrs. Frank Walton, a licensed woman engineer, who, as chief engineer, managed the exhibit with rare skill and judgment.

The battery of improved Root boilers used at the Electrical Exposition, we may add, was an exact duplicate of the six batteries of Root boilers used at the celebrated tunnel plant of the Baltimore & Ohio Railroad, in Baltimore, Md.

KEUFFEL & ESSER CO.'S EXHIBIT.

AMONG the exhibits which were not composed of electrical appliances, that of the Keuffel & Esser Company was of special interest. They exhibited their well-known Paragon

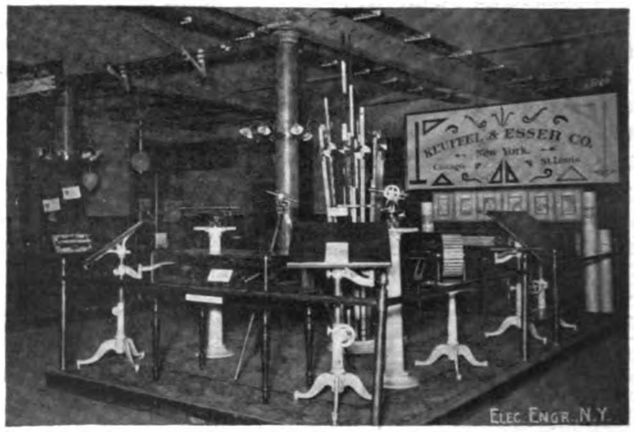

EXHIBIT OF THE KEUFFEL & ESSER CO.

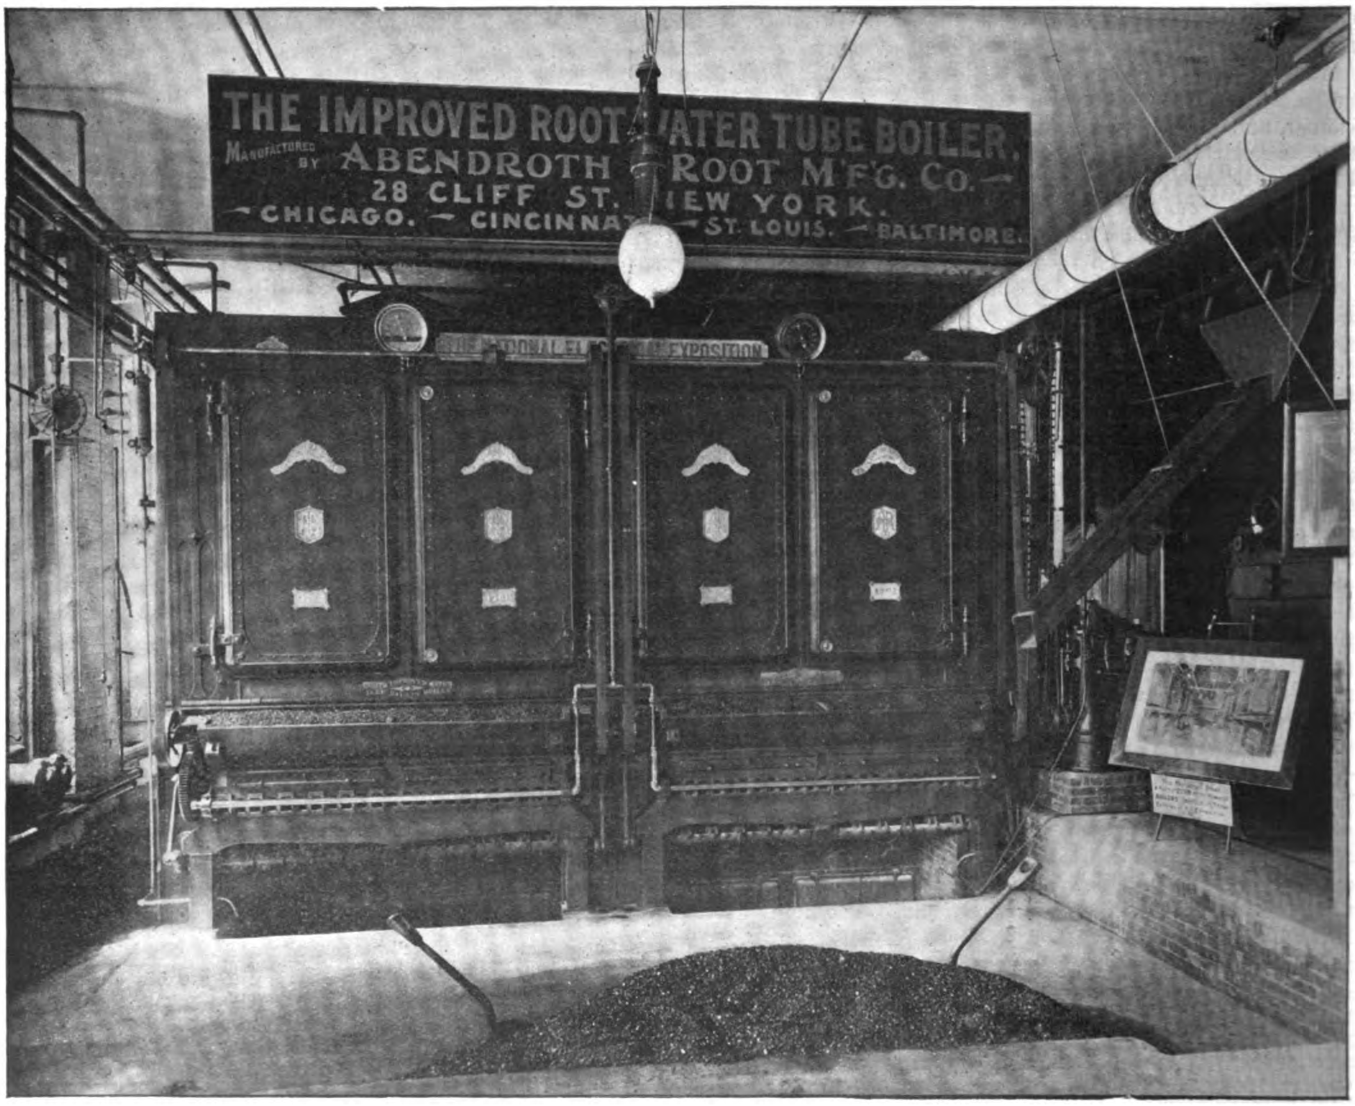
and other drawing instruments, protractors, Mannheim, Duplex, Fuller and Thacher slide rules, reckoning machines, levels, transits, drawing tables, and what is generally comprised under the name of drawing tools. An unusually fine blueprint



BOILER PLANT CONSTITUTING THE EXHIBIT OF THE ABENDROTH & ROOT MFG. CO.

made on their Helios paper was exhibited in a very practical blueprint frame and was a conspicuous part of their exhibit. They also exhibited a heliograph of the pattern adopted by the United States Army. It was labeled "Telegraphing without Electricity," and found many interested examiners. We print in this issue a view of their interesting and well arranged exhibit.

THE IDEAL ELECTRIC CORPORATION.

THE accompanying illustration represents the booth of the Ideal Electric Corporation at the Electrical Exposition. This exhibit included a full line of the well-known La Roche alternators and there were also the focusing lamps of which this company makes a specialty, as well as the Ideal arc lamps. To the right of the illustration is shown a combination individual street fixture and converter which was directly connected across the 1,000 volt main of an alternating circuit. Their alternating arc lamps were distributed through various

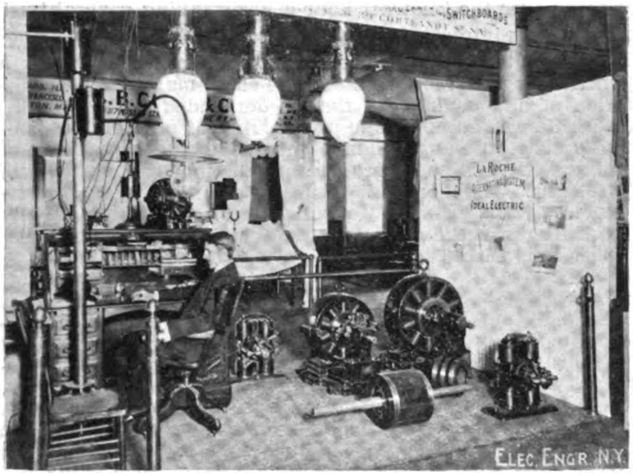


EXHIBIT OF THE IDEAL ELECTRIC CORPORATION.

parts of the building and operated on currents of various frequencies without any change or adjustment.

A prominent feature of the exhibit was a 5 horse-power direct current motor which was self-regulating and could be operated at any speed between 800 and 1,500 revolutions per minute simply by moving the rocker arm about the commutator. The change of speed was accomplished without any sparking at the brushes, and the full horse-power was developed at any speed within the limits of speed mentioned. Other types of direct current machines were also exhibited. The booth was in charge of Mr. F. A. La Roche, the vice-president and general manager of the Ideal Electric Corporation.

OBITUARY.

DEATH OF MR. HARRY J. SMITH.

While inspecting his barn at Washingtonville, near Plainfield, N. J., on Sunday last, Mr. Harry J. Smith, the well-known operating superintendent of the New York Edison Company, slipped from a rafter and fell to the floor, fifteen feet below. Mr. Smith was picked up unconscious and remained in that state for many hours. Examination showed that he had suffered a fracture of the skull and also internal injuries of a serious nature. As we go to press we learn that Mr. Smith expired after a few brief intervals of consciousness. Mr. Smith leaves a widow and three children to whom we extend our most sincere sympathy in their dire affliction.

MARRIED.

MR. EDWARD E. HIGGINS was married to Miss Mary Austin White on June 10, at West Roxbury, Mass. We extend our heartiest congratulations.

ROENTGEN RAYS.

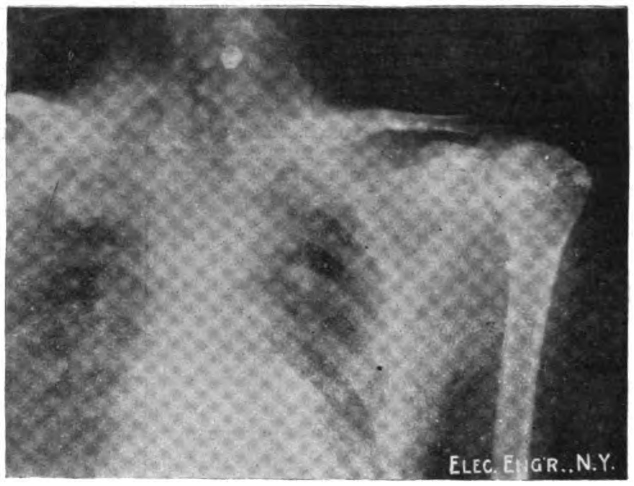
ROENTGEN PICTURE OF CHEST AND SHOULDER.

BY WILLIAM J. MORTON, M. D.

THE picture as here illustrated is a reduction of a 17 x 12 inch negative, converted, in the usual manner, to a positive, in order to show the bones in their natural white color. To a surgeon's eye the acromion and coracoid processes of the shoulder blade are clearly shown in their relations to the head of the humerus, or arm bone, and also the end of the clavicle, or collar bone, is shown in its relations to the shoulder joint. We have, in short, an inner inspection in a living person of this rather complicated joint, the shoulder, and there can be no doubt that in defined pictures of this nature even very slight deformities and diseases would be detected.

It is noticeable that the front portions of the ribs are not shown; only the posterior portions lying nearest to the sensitized plate appear; also the breastbone was sufficiently dense to almost entirely obstruct the X-rays.

A collar button at the back of the neck is taken through the backbone. In some of my negatives the dark outline of the



ROENTGEN RAY PHOTOGRAPH OF CHEST AND SHOULDER OF LIVING MAN. TIME OF EXPOSURE, EIGHT MINUTES, WITH AYLSWORTH & JACKSON FLUORESCENT SCREEN.

heart and liver is shown as well as the outlines of tumors in the brain; but this is evidently for purposes of demonstrating the location of organs, an over-exposure, and does not, therefore, indicate the outlines of the heart. I have also taken an excellent picture of the adult pelvis and thighs.

The question of the fluorescent screen is an important one in advancing the surgical usefulness of the X-ray. I have made many experiments, some of them conflicting in the interpretations which they suggest, but my present opinion is that the screen as made by Messrs. Aylsworth & Jackson makes quick exposures possible and at the same time affords sufficiently accurate definition of the parts. The very slight loss in softness, modulation and sharpness of detail of the negative made without the aid of the fluorescent screen is more than compensated for by the avoidance, when the screen is used, of the weariness of an enforced posture during the longer time.

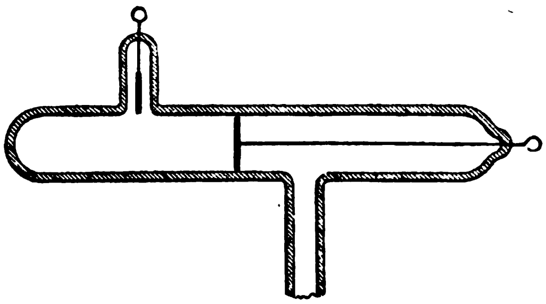
THE X-RAY IN MINING.

Mr. J. W. Scott, a well-known geologist and coal operator, residing at Lloydsville, Cambria County, Pa., claims to be the first to apply the Röntgen process to the discovery of hidden things under the surface of the earth. When the discovery of Röntgen was made public he set about to use it in his work on the Allegheny Mountains, where he is interested in coal developments. The celebrated E vein of coal has for forty years been the object sought after by geologists, prospectors, miners and operators all over the mountain.

Mr. Scott has made some experiments in this direction, the results of which, he claims, will greatly aid the science of locating the mineral deposits of the earth.

COLARDEAU'S X-RAY TUBE.

THE accompanying illustration shows in full size a new form of Crookes tube designed by Mr. E. Colardeau and by means of which very clear photographs have been taken. The tube is cylindrical and of small diameter, and contains a cathode of a diameter almost equal to that of the tube. This is pushed down into the tube to within a short distance of the anode wall. As the small capacity of this tube causes a very



THE COLARDEAU X-RAY TUBE.

rapid alteration of its degree of vacuum owing to the passage of the discharge, it is necessary in order to render it practical to connect to it a communicating vessel sufficiently large which obviates this inconvenience. This small tube is a very powerful source of X-rays. With five minutes' exposure it gave very sharp pictures of objects inclosed in a leather portfolio, using a coil which gave a six-inch spark. The distance of the object from the tube was 15 cm. One minute's exposure gave pictures fairly good, and even one second was sufficient to give feeble but clear pictures of bodies through two sheets of black paper at a distance of 5 cm.

TELEPHONY AND TELEGRAPHY.

MR. KEELYN ON THE DRAWBAUGH PATENTS.

The proposed bill for the issuance of the Drawbaugh patents reported by the Senate Committee has been surrounded by a good deal of mystery. The published statements indicating that there would be another attempt at monopolizing patents on telephones, has, as might have been expected, drawn forth strong protests, among them one from James E. Keelyn, of the Western Telephone Construction Company, Chicago, Mr. Keelyn asserts that he will use every legitimate means and all his energy to prevent favorable action by the United States Senate upon what he calls "another outrageous patent iniquity." Mr. Keelyn asserts that the Drawbaugh applications are owned by a syndicate and that this syndicate proposes to sell to or arrange with the Bell Company to operate these patents if granted.

Mr. Keelyn says that the Drawbaugh claims have been rejected by the Patent Office proper, upon the ground of previous public use, and that there has been another shrewdly operated plan to force the issue of these patents against the advice of the Patent Examiners, and that failing, to lobby Congress to do what otherwise could not be done. It is further claimed by Mr. Keelyn that the present Government suit against the Bell patents would be a simple farce in view of the expiration of the patents, if it were not for the serious fact that the purpose of these suits by arrangement of the Bell Company could be of the most dangerous character. These suits by the Government allege that the Drawbaugh patents anticipated the Bell patents. Now if the Courts hold this to be the case, the Bell patents would have no effect as anticipated, provided Congress should pass favorably upon the issuance of the Drawbaugh patents.

"Briefly," says Mr. Keelyn, "the Supreme Court will hear the matter on October 19. Even if the Supreme Court does not pass adversely upon the patents, there is no question whatever that they could not be made to stop the use of high grade telephones as efficient as the Bell Company's. Therefore the Bell people are trying in another way to regain their weakened hold upon the telephone business. They feel that their efforts at intimidation and bringing patent suits have failed, and they find that their resort to cutting rates in order to stifle competition have also failed.

"It is of the highest importance that these Drawbaugh claims be stamped out before they get life enough to be used to intimidate the public, which seems is their only purpose, as the Drawbaugh apparatus would be worthless in practice at the present date."

MISCELLANEOUS.

CHARGING FOR ELECTRIC CURRENT.

BY WARREN B. LEWIS.

THE article on "Charging for Electric Light Service," by Mr. Farnsworth, in The Electrical Engineer of June 3. cannot fail to be of interest to those concerned in the production and sale of the electric current as a commodity. The article most ably presents a scheme of charging that is certainly desirable from at least the point of view of the central station manager and to be heartily indorsed by the stockholders; but the writer of this communication begs to differ as to the improvement over the kilowatt hour charge, taking general business principals into consideration.

The distribution of the electric current is entered into by a corporation or individual in much the same manner as the distribution of any commodity that is demanded by the public, and with the same knowledge presumably of possible profit or loss. To distribute any commodity requires the investment of capital and there is no assurance that the money invested will yield returns. The merchant has fixed expenses which are independent of the demand for his goods, but which are included in the price he gets; and his experience in his business furnishes him with the information which will enable him to make such a charge as will yield a profit. The electric current is a commodity, the sale of which is undertaken by a corporation or individual, who supposedly knows the chances of profit and loss and the expenses of selling. The fixed charges are no more entitled to be guaranteed by the customers than those of a dry goods house. If the demand fluctuates, as it does in every commodity, or if the customer leaves to patronize another concern, there is no reason why he should pay for the privilege of having the right to purchase if he chooses; for the distributing company exists to solicit trade, not to require a bonus for allowing individuals to buy.

Mr. Farnsworth's idea is a good one if the electric light company is made a mutual or co-operative one, in which each user becomes a directly interested stockholder, the magnitude of his patronage determining his responsibility and entitling him to a yearly return of his share of the undivided profits. In such a plan each customer guarantees the fixed expenses in proportion to his patronage and pays equally for the commodity. He is entitled to a yearly statement and a dividend if there is a profit. But to guarantee fixed charges, pay for the commodity and see the promoter pocket the profits, is very much like "heads I win, tails you lose."

The basis of charging for any article of commerce is a certain price per unit, and the electric current does not differ in its distribution from anything else. It is a misfortune that the production and demand takes place under circumstances that make the business one of hazard with small profit; but that is due to fault of manufacture if the term may be applied. rather than to the fault of manner of selling. The kilowatt hour is a unit that is as perfect in its application as a measure as the quart, pound or yard. In consideration of the purchase of a large quantity, or of quick payment, a discount is allowed; but if the discount is not uniform to all, or if the measure is inaccurate, the fault lies in the merchant, not in the system. The electric current, to be a profitable commodity at lower cost than at present, must be more uniformly produced for consecutive hours. No one appreciates that more than the writer; and a practical method of producing current for ten hours steadily, to be distributed as it is demanded, would be hailed with enthusiasm. But the burden of the present method belongs to the station manager, and his experience and undivided attention will determine a proper kilowatt hour charge in order to do a profitable business.

Until electric current is sold on the co-operative plan the investor must trust to careful management to find a profit in the business, taking equal chances with other investors. There is more room for profit in reorganizing plants that could not make money at 50 cents a kilowatt hour, and producing current at a minimum cost, than in getting the customers to guarantee fixed charges with no assurance that the kilowatt hour charge is going to be any less, or that he is to profit by a method of charging that would induce every capitalist in the country to build an electric light plant.

To make such a plan as Mr. Farnsworth's equitable and fair

to the customers, frequent statements showing the proportion of fixed charge for each one would have to be made and a fluctuation in the number of customers would entail a corresponding change of rate. Numerous accounts with each one would have to be kept to determine whether he was profitable or not. On the kilowatt hour basis, the station manager should certainly know what a kilowatt hour costs delivered, and there is not much room for doubt as to the desirability of retaining each customer.

All business is dull at times. The lighting business is no exception and the most rigid economy must be practiced, without lowering the standard, to pay expenses; but the expense of producing one unit belongs wholly to the producer, and the results will be directly proportional to his appreciation of that fact and his ability and experience.

SOCIETY AND CLUB NOTES.

NORTHWESTERN ELECTRICAL ASSOCIATION CONVENTION.

The fourth semi-annual convention of this association will be held at Marinette, Wis., commencing at 9 a. m., on Wednesday, July 15 next. Papers on "Insurance," "Incandescent Lamps," "Rights of Electrical Companies," "Lightning Arresters," "Alternating Current Motors," "Storage Batteries," "The New York Convention and Exposition," and other subjects, will be presented and discussed. The Entertainment Committee's programme includes picnics, bathing and boating parties, log-rolling frolics, bay excursions, trolley parties, banquet, etc. Hotel rates have been arranged at $2 and $2.50 per day. Indications point to a large attendance, and rooms should be secured in advance. Address H. C. Higgins, Marinette, Wis. The Western Passenger Association has granted a one and one-third fare on the certificate plan from all points in its territory to Marinette and return, one hundred certificates being necessary to secure this rate.

Special through cars for members and their friends will be attached to the Chicago and Northwestern fast train leaving Chicago at 3 p. m. on Tuesday, July 14; Waukegan, 3:50; Kenosha, 4:08; Racine, 4:22; Milwaukee, 5; Oshkosh, 7:15; Neenah, 7:37; Appleton, 7:47; Kaukauna, 8:02; DePere, 8:29; Green Bay, 8:50; Oconto, 9:43, and arriving at Marinette at 10:20 p. m.

Intending attendants are requested to communicate with Mr. Thos. R. Mercein, secretary, at Milwaukee, Wis.

THE CANADIAN ELECTRICAL ASSOCIATION.

THE sixth annual convention of the Canadian Electrical Association will be held in Toronto, Canada, June 17 to 19, 1896. The headquarters of the convention will be in the council chamber of the Board of Trade.

The following papers will be presented:

"Ocean Cables" (Historical), by Chas. P. Dwight, Toronto; "Acetylene Gas" (with demonstrations), by Geo. Black, Hamilton; "Meters," by James Milne, Toronto; "Consideration and Discussion of the Government Electric Light Inspection Act;" "Some Central Station Economics," by P. G. Gossler, Montreal; "Power Transmission by Polyphase E. M. F.'s," by Geo. White Fraser, Toronto; "Operating Engines without a Natural Supply of Condensing Water," by E. J. Phillip, Toronto; "The Outlook for the Electric Railway," by F. C. Armstrong, Toronto.

The social features include a lecture by Mr. James Milne, showing demonstrations of Röntgen rays, and several excursions to nearby points of interest.

REPORTS OF COMPANIES.

CHICAGO EDISON CO.'S ANNUAL MEETING.

THE annual meeting of the stockholders of the Chicago Edison Company was held June 8. President Insull submitted the yearly report. He prefaced the statement by noting that the company had from April to October, 1895, increased net earnings available for dividends 8 per cent. over the net earnings of the same period the previous year. From October, 1895, to April, 1896, the increase was 25 per cent. over the same time of the previous year, making the average increase for the year a little over 22 per cent., rendering net earnings available for dividends about 8¼ per cent. for the twelve months.

For the last two months (April and May) earnings show a generous improvement—in fact, about 9 per cent. has been earned. Mr. Insull then explained the contemplated bond issue. There will mature between now and next January $2,500,000 six per cent. bonds. There is also a floating debt amounting to $300,000. It was the intention of the directors to remove these obligations by issuing $3,500,000 bonds, using the balance (about $700,000) for extension. The president said the remainder of the proposed issue, $2,500,000, would probably not be made for some time—not this or next year—but it was deemed advisable to make the amount sufficiently large to meet all exigencies for years to come. If bonds were placed for the sum actually required ($3,500,000) later, when more money became essential, it would be necessary to obtain it on second mortgage bonds, since the present issue is a first mortgage. The stockholders thereupon sanctioned the issue. By exchanging the different 6 per cent. obligations for the new 5 per cent. bonds the company saves $25,000 per annum in interest.

The following directors were elected: Edward L. Brewster, R. C. Clowry, J. W. Doane, F. S. Gorton, Samuel Insull, R. T. Lincoln, Joseph Leiter, J. J. Mitchell, E. M. Phelps, Byron L. Smith, A. F. Seeberger, A. A. Sprague, Lambert Tree.

WESTINGHOUSE CO.'S STOCK INCREASED.

A special meeting of the stockholders of the Westinghouse Electric and Manufacturing Company was held on June 5, at which it was voted to increase the capital stock from $10,000,000 to $15,000,000. About 140,000 shares were represented at the meeting, which voted unanimously for the increase.

Announcement was also made by the directors of the discontinuance of about 300 patent suits under the agreement entered into with the General Electric Company.

THE NEW YORK EDISON CO.'S EARNINGS FOR MAY.

The Edison Electric Illuminating Company, of New York, report the following earnings for May:

	1896.	1895.	Increase.
Gross	$169,166.57	$155,858.51	$13,308.06
Net	77,751.92	75,146.35	2,605.57
Gross, 5 months	$946,836.62	$868,310.79	$78,525.83
Net, 5 months	477,120.60	417,728.60	59,392.00

LEGAL NOTES.

GENERAL ELECTRIC CO.'S SUITS ON THE UNDERRUNNING TROLLEY PATENT.

Suit has been brought in the United States Circuit Court by the General Electric Company against the Nassau Electric Railroad Company, of Brooklyn, for infringement of the Vandepoele patent, No. 495,443, of April 11, 1893, covering the underrunning trolley. The order issued by Judge Lacombe enjoins the Nassau Company from adding to its present equipment pending the hearing of the question of injunction which has been set for June 26.

The suit brought by the General Electric Company against the New York, Elmsford and White Plains Railway Company was professedly to enjoin the use of four trolleys used by that road. The real object was to compel that railway to buy its entire electrical equipment of the General Electric Company, throwing out the present Walker equipment of motors, trolleys, etc. The Walker Manufacturing Company was sued with the New York, Elmsford and White Plains Company, but took the position that it had not been properly served, and was therefore not in court. The court declined to issue an injunction against the Walker Company, declined to issue any injunction against the four trolleys referred to, but enjoined the New York, Elmsford and White Plains Company from further infringement.

ST. LOUIS UNDERGROUND WIRE ORDINANCE DECLARED VOID.

The Supreme Court, sitting en banc, holds, in the case of the St. Louis Underground Service Company against the street commissioner of St. Louis, that all city ordinances granting corporations the right to lay conduits and subways for electric wires and other similar uses, are void. The city holds the streets in trust and cannot grant their use for private purposes. This opinion is of great importance in view of the proposed subway system now contemplated by St. Louis.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED, JUNE 9, 1896.

Batteries:

AUTOMATIC ELECTRICAL BATTERY CUT-OUT. H. W. Clelland and F. J. Madden, Wilkinsburg, Pa., 561,565. Filed Dec. 11, 1895.

A float rod and means for making contact thereby when liquid in jars reaches a certain depth.

ELECTRIC BATTERY ELEMENT. G. J. Ortner, Pueblo, Colo., 561,810. Filed Feb. 18, 1896.

A zinc element for a battery, comprising a hub portion having a tapered opening, and an amalgamated zinc supporting stem having a tapered portion at its lower end.

GALVANIC BATTERY. T. E. Fogalsang, Sacramento, Cal., 561,878. Filed July 29, 1895.

Consists of an acid electrolyte mixed with a solution of eucalyptus.

Storage Batteries:

ELECTRICAL ACCUMULATOR. Gaston de Schrynmakers de Normael, Brussels, Belgium, 561,872. Filed May 1, 1895.

Negative material therein, and the depolarizing peroxide arranged in direct contact with the negative material.

Conductors, Conduits, and Insulators:—

ELECTRICAL CONNECTION. T. Grutting, St. Paul, Minn., 561,951. Filed Aug. 19, 1892.

A base or receptacle having an annular groove with gates, a contact ring therein, and the connecting screw secured in the center, and provided with an annular rib or guard.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. C. P. Steinmetz, Lynn, Mass., 561,735. Filed Jan. 6, 1894.

The combination of an alternating current generator, of armature conductors arranged in sections angularly displaced in such manner that such sections tend individually to generate currents substantially 60 degrees apart in phase, with means for converting such displaced currents into a three-phase current system.

Dynamos and Motors:—

ARMATURE FOR DYNAMO ELECTRIC MACHINES. F. D. Ide, Eau Claire, Wis., 561,590. Filed April 14, 1896.

The combination of a core with armature coils disposed thereon, and U-shaped retaining links adapted to secure said coils in position.

DYNAMO ELECTRIC GENERATOR. B. G. Lamme, Pittsburg, Pa., 561,593. Filed Sept. 4, 1895.

Two commutators and two sets of armature coils arranged in pairs, the pairs of each set being at right angles to each other, and the two sets being connected in series through the commutators.

FORM FOR WINDING ARMATURE COILS. J. A. Webber, Lynn, Mass., 561,636. Filed Jan. 25, 1896.

Comprises a suitable base, means for confining the coil, and a series of terraces or grooves upon which one part of the coil is wound.

THERMO-ELECTRIC GENERATOR. H. B. Cox, Hartford, Conn., 561,657. Filed Feb. 13, 1895.

Comprises a supporting casing forming a water jacket, and the removable active element forming the inner wall of the water space and removable from the casing without disturbing the same.

ELECTRIC MOTOR. W. H. Cooley, Brockport, N. Y., 561,699. Filed March 12, 1895.

In combination with the armature and field in an alternating current machine, rectifying devices carried by such armature or field and co-operating with others carried by a third element, and means for establishing and maintaining a relative synchronous rotation between such third element and the armature or field carrying such rectifying devices.

ELECTRIC MOTOR. W. H. Cooley, Brockport, N. Y., 561,700. Filed March 12, 1895.

Two magnetically separate series of field magnets, mechanically united and each energized by alternating currents of different phase and two magnetically separate armatures located in operative relation to such magnets.

DYNAMO ELECTRIC MACHINERY. F. G. Mayer, Chicago, Ill., 561,803. Filed Oct. 18, 1895.

An outer casing and a core concentric therewith, an armature consisting of a core adapted to revolve between said outer casing and said concentric core and having a series of concentric metallic cylinders mounted thereon, said cylinders being insulated from each other and from said core.

ELECTRIC MOTOR AND MOTOR GENERATOR. W. H. Cooley, Brockport, N. Y., 561,867. Filed May 21, 1895.

Consists in the combination, with the elements of a rotatory transformer, of means for producing in one of such elements a rotatively progressing series of fields opposed to a third element to which it bears the relation of armature or field.

CONTINUOUS-CURRENT RECTILINEAR MOTOR. P. W. Leffler, Chicago, Ill., 561,899. Filed Oct. 8, 1895.

Means whereby a continuous current may be supplied to an electromagnetic element carried upon a vehicle to produce shifting magnetic poles adapted to react upon fixed poles situated along the line of travel of the vehicle, whereby the vehicle is propelled forward.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. S. Bergmann, New York, 561,560. Filed Feb. 27, 1895.

Relates to the feed mechanism.

Measurement:—

ELECTRIC METER. R. O. Hood, Danvers, Mass., 561,711. Filed Jan. 26, 1895.

The revolutions of an electric motor are registered to give an indication of the consumption of electricity.

ELECTRICAL MEASURING INSTRUMENT. H. A. Rowland, Baltimore, Md., 561,918. Filed Oct. 2, 1895.

The combination with a dynamometer, of a shunt box connected to the terminals of the dynamometer, and a pivoted arm making frictional contact with the base of the instrument and carrying a reading scale.

ELECTRICAL MEASURING INSTRUMENT. H. A. Rowland, Baltimore, Md., 561,919. Filed Oct. 2, 1895.

A wall instrument furnished with a telescope and scale or lamp and scale hinged to it and capable of being folded against the wall when not in use.

ELECTRIC SELF-WINDING CLOCK. R. A. Mitchell, Brooklyn, N. Y., 561,943. Filed Jan. 16, 1895.

Employs a single line wire.

Miscellaneous:—

ELECTRICAL APPARATUS FOR CONTROLLING MOTION OF CRANES, ETC. J. A. Essberger and A. W. Geyer, Berlin, Germany, 561,777. Filed Sept. 29, 1894.

Means whereby a single lever is employed.

ELECTRIC ELEVATOR. H. R. Smith, Chicago, Ill., 561,828. Filed March 16, 1896.

A hoisting motor, comprising a solenoid having a stationary core, and a movable coil, said coil connected to the car hoisting cable.

ELECTRIC CHIME. J. H. Gerry and F. M. Schmidt, Brooklyn, N. Y., 561,881. Filed March 18, 1895.

Railways and Appliances:—

RAIL BOND. L. Cook, Worcester, Mass., 561,698. Filed April 11, 1896.

Consists of an inner soft metal split sleeve, having a central hole to receive the wire and an outer split hard metal sleeve having a cylindrical outer surface with a tapered end.

ELECTRIC RAILWAY. W. M. Schlesinger, Philadelphia, Pa., 561,821. Filed Aug. 4, 1895.

A conduit system employing traveling connections and means for lighting the cars with independent current.

ELECTRIC RAILWAY. C. E. Stanley, Gallipolis, O., 561,830. Filed Sept. 27, 1895.

The conductor is laid in a narrow groove in the web of one of the rails and connection is made through the wheel.

ARC INTERRUPTER FOR STREET CAR CONTROLLERS. G. Valley, Cleveland, O., 561,838. Filed Feb. 10, 1896.

Comprises an electromagnet internal to the drum and having projections from its pole pieces extending through the drum in proximity to the contact pieces thereof.

REVERSING AND CUT-OUT SWITCH USED IN ELECTRIC STREET CARS, ETC. G. Valley, Cleveland, O., 561,839 Filed Feb. 26, 1896.

Provides a switch by which the reversing of the motors as well as the cutting-out of either motor, may be effected by a single switch, and the usual separate reversing switch and separate cut-outs may be dispensed with.

ELECTRIC RAILWAY. P. W. Leffler, Chicago, Ill., 561,898. Filed Aug 12, 1895.

Details of construction.

Regulations:

AUTOMATIC MOTOR STOP. W. M. Wood and J. C. Miller, Elmira, N. Y., 561,846. Filed Oct. 21, 1895.

Comprises a governor, trip mechanism in position to be struck when the governor is actuated by undue speed in the motor, and an electric circuit closer retained by the trip mechanism, and a stop mechanism controlled by the electric circuit.

AUTOMATIC MOTOR STOP. W. M. Wood and J. C. Miller, Elmira, N. Y., 561,847. Filed Oct. 21, 1895.

A rod acted upon by a weight thrown out by centrifugal force, and one end of said rod being adapted to strike the terminals of an electric circuit.

Switches, Cut-Outs etc:—

ELECTRIC SWITCH. M. Guett, Hartford, Conn., 561,581. Filed Nov. 29, 1895.

A pivoted arm connected by a spring to a hand controlled pivoted lever.

ELECTRIC SWITCH. J. L. Hornig, St. Louis, Mo., 561,588. Filed Aug. 26, 1895.

Comprises a spring actuated disc of insulating material, a conductor plate arranged in said disc in such a manner that its ends appear on the periphery, two contacts which co-operate with said conductor plate and suitable mechanism for tripping said disc.

Telegraphs:—

TELEGRAPH RELAY. E. Butler, New York, 561,653. Filed June 15, 1893.

Consists of a pair of electromagnet coils, provided with an armature opposed to both cores and a stationary solenoid surrounding the shaft of said armature.

Telephones:—

REGISTER FOR TELEPHONES. E. L. Morey, Portland, Ore., 561,601. Filed Aug. 13, 1895.

Comprises a fork for engaging with the receiver and means for actuating indicating mechanism.

TOLL COUNTER FOR TELEPHONE LINES. G. P. Seligmann-Lui, Paris, France, 561,619. Filed Aug. 18, 1894.

Comprises apparatus at the central station for normally preventing the passage of telephonic currents over said line, a circuit controlling device at the terminal station for operating said apparatus at the central station to thereby permit the passage of telephonic currents and a recording instrument at the terminal station, operated by said circuit controlling device.

CIVIL SERVICE EXAMINATION FOR ELECTRICAL EXPERT TO THE N. Y. STATE RAILROAD COMMISSION.

A competitive civil service examination has been ordered on June 26, at Albany, for the position of electrical expert under the State Railroad Commission. This position was created by the last Legislature, in order to secure a competent person to look after the construction of electric railroads. Candidates must be electrical engineers, thoroughly conversant with the construction and operation of electrical railroads and power stations, and competent to inspect and make reports on them in all departments.

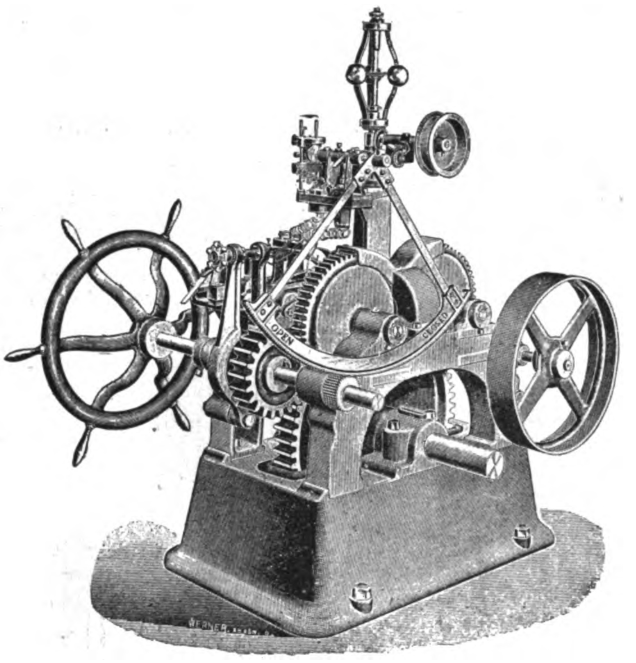
Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

REPLOGLE RELAY WATER-WHEEL GOVERNOR.

WE illustrate herewith the new "Relay" water-wheel governor built by the Replogle Governor Works, of Akron, Ohio, which has recently been submitted to a most successful test upon electric street railway work, which is perhaps the most severe service to which it could be put.

In this test it was intended to show what can be done in the extreme cases, and it was the aim to have the test made under



THE REPLOGLE WATER WHEEL GOVERNOR.

the very worst conditions. The time chosen was during a heavy snowstorm, with fully three inches of new snow on the track, and the success in obtaining bad conditions is fully shown by the fact that the circuit breakers opened ten times during a thirty minutes' test. This, of course, makes instantaneous changes of from full load to no load. It is shown that in only one case did the speed rise to slightly exceed 5 per cent. from normal.

The electric railway in question is that of the Citizens' Street Railway Company, Fishkill-on-Hudson, N. Y., connecting with Matteawan and Fishkill villages. There are seven miles of road. The maximum grade on this road is 8½ per cent. There are two portions nearly one-half mile long each, that average about 5 per cent. grade. There are some short curves and some of them are found on the heavy grades. The main line is giving a ten-minute service, and the suburban line an hourly service. At the time of the test four double motor cars were in operation, using from 30 to 50 horse-power each.

The power for this road is furnished from a pair of forty-eight-inch Rodney-Hunt water-wheels, under about fifteen feet head of water, and is conveyed by belts to a countershaft, which in turn drives by belt a General Electric "M. P. 100" generator. During the test readings were taken from a Shaeffer & Budenberg tachometer, a Weston voltmeter, and a General Electric Company ammeter. The readings began at 12:38 p. m., and were taken every ten seconds for thirty minutes. The normal speed was 105 revolutions per minute on the wheel shaft, and the average voltage was 550. The readings showed that there were 80 amperes of current, 540 volts pressure, and 103 revolutions on water-wheel shaft, at the end of the first minute. At the end of the second minute there was no current, 546 volts and a speed of 104 revolutions on water-wheel shaft, and twenty seconds later there were 110 amperes used, and the voltage had dropped to 516. The reading ten seconds later showed no current, 564 volts and 107 revolutions. Over one-half of the load dropped off in ten seconds, and yet the speed was only two revolutions above normal. This is less than 2 per cent. increase of speed on a 55 per cent. decrease of load.

At twenty-six minutes and forty seconds the readings were 200 amperes, 529 volts, and speed 101. During the following ten seconds the circuit breaker went out, and at the end of these ten seconds the readings showed 140 amperes, 560 volts and 105 revolutions, normal speed.

The above test shows clearly that water-power government has advanced to such a stage that it is safe and reliable, even under the most severe conditions, and it will therefore, we believe, be of considerable interest to street railway and electric power operators.

WILLYOUNG IMPROVED INDUCTION COILS AND VARIABLE CONDENSERS.

MESSRS. E. G. WILLYOUNG & CO., of Philadelphia, have recently placed on the market an improved line of induction coils which are intended to compare in quality with the best types of foreign make, but at very much lower prices. Fig. 1 illustrates the new Willyoung coil, from which it will be seen that the general plan of construction, especially as regards the "hammer head" vibrator, is similar to the English Apps coils, the most famous of which was made for Mr. Spottiswood and gave a spark in excess of forty inches.

The iron core in each coil is of best grade Norway iron wire, especially annealed, and each component wire is covered with a thin coat of shellac. The core lies inside of the primary coil and is inclosed in a hard rubber tube of sufficient length to render impossible any sparking of the secondary coil to the core or the primary coil. The secondary coil is wound in a large number of small sections each insulated from its neighbors, and the coil as a whole saturated with special insulation by an original method, in such a manner as to thoroughly exclude air, thus preventing any heating of the solid dielectric by bombardment, and consequent ultimate softening and breakdown of the insulation.

The electrical constants of the Willyoung coils have been determined with such care and accuracy that high efficiency is obtained, the maximum guaranteed spark being secured by minimum amount of wire in secondary coil and with least possible weight of the iron core. For example, in coils of six, eight, and ten-inch spark rating, not more than one pound of No. 34 B. & S. wire is used per inch of spark length, while the discharge in each case is exceptionally solid and heavy.

A new feature of great importance incorporated by Messrs. Willyoung & Co. in their induction coils is a variable condenser as substitute for one of single value as placed in the base of coils of ordinary design. The function of a condenser, as is well known, is to return through the primary coil the energy of self-induction produced in it at break in order to hasten

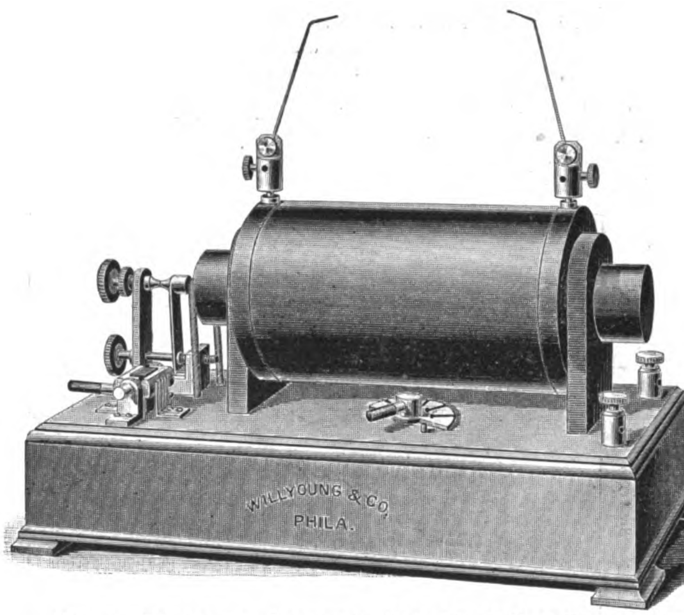


FIG. 1.—WILLYOUNG INDUCTION COIL FOR X-RAY EXPERIMENTS.

the demagnetization of the iron core and thus produce a sudden rise of E. M. F. in the secondary coil. As this self-induction energy depends upon the value of the primary current in use it will be evident that a condenser of but one capacity is only suited for a particular exciting current and a particular primary spark length, without variation in either case. Even

the change in electrostatic capacity produced by varying the vacuum tube (such as in X-ray work) is sufficient to disturb the proper balance between self-induction and capacity. This not only reduces spark length in the secondary coil, but causes actual heating and combustion of the primary sparking points, with the result that repairs are often necessary.

Messrs. Willyoung & Co. are also making a line of variable condensers for general experimental work, such as the study of resonance phenomena, alternating current investigations, etc. Fig. 2 represents a ten-microfarad variable condenser with ten sections of 1-10 microfarad each and nine sections of one microfarad each.

The method of construction will meet a demand for condensers, the capacity of which can be varied much more quickly and by much finer subdivisions than is possible in the

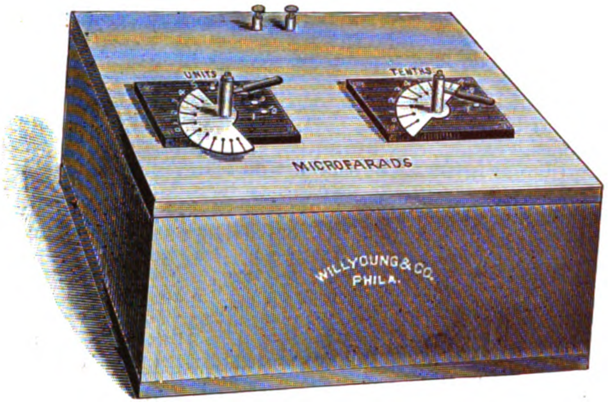

FIG. 2.—WILLYOUNG VARIABLE CONDENSER.

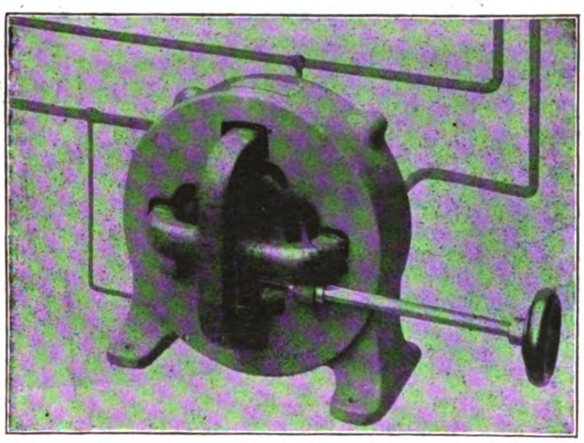
former "plug-in and plug-out" forms. The regulating switches, as in a controlling rheostat, instantly change the condenser capacity with perfect smoothness of operation and effect.

For material of construction, tinfoil and a specially selected brand of unsized paper are cut to proper dimensions and stacked together dry. These pieces are then subjected to a peculiar insulating process by which every part is permeated with a solid dielectric. Both air and moisture are thoroughly and permanently removed. The condensers are capable of "standing up" continuously and without injurious heat effect on 500 volt alternating circuits, while direct currents of much greater potential can be safely employed.

All the apparatus manufactured by Messrs. Willyoung & Co. is sold through their sales agent, Mr. James G. Biddle, 944 Drexel Building, Philadelphia, who will be glad to send descriptive circular, No. 170, to interested parties.

G. E. FEEDER POTENTIAL REGULATOR.

A SIMPLE and practical device for controlling the voltage on alternating current circuits is the new feeder potential regulator, type M. R., constructed by the General Electric Company, in which, by the mere turning of the iron core by



G. E. FEEDER POTENTIAL REGULATOR.

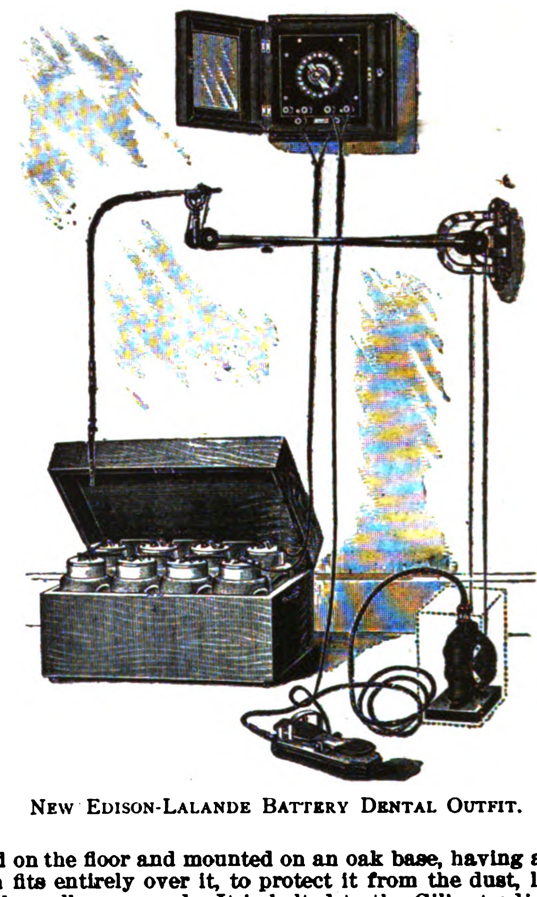
a small hand wheel, the effective voltage is raised or lowered, no movement of contacts or changes of connection being necessary. The principle involved is that of varying or reversing the mutual induction of the coils by change in position of the iron core, one coil being connected in shunt to the circuit, the other in series.

The utilization of this principle permits of continuous variation in the voltage as the core is turned without any of the abrupt, intermittent steps so noticeable with other devices for feeder regulation. This regulator acts as a transformer, not as a reactive coil; its effect in raising or lowering voltages is practically independent of the current in the circuit to which it is connected.

In construction the device is extremely simple, and consisting, as it does, of laminations of simple form and large machine wound stationary coils, it is practically indestructible. The uses of this regulator are numerous. It may be employed as a regulator for controlling the voltages on alternating current feeders; as a dimmer for theater lighting; as a controller for series street circuits and as a pressure adjuster on different branches of unbalanced polyphase or three wire circuits. It may also be employed as a transformer of adjustable ratio wherever it is desired to obtain alternating currents of variable pressure. It can, of course, be wound for any voltage.

NEW EDISON DENTAL BATTERY OUTFIT.

WE illustrate below a new dental battery outfit just brought out by the Edison Manufacturing Company, a brief description of which may prove interesting to our readers. The battery consists of eight cells of the well-known Edison-Lalande battery, type "W," which is largely used for battery dental outfits, on account of its long life, freedom from waste and absolute constancy of current. The reversible motor is



NEW EDISON-LALANDE BATTERY DENTAL OUTFIT.

placed on the floor and mounted on an oak base, having a cover which fits entirely over it, to protect it from the dust, leaving only the pulley exposed. It is belted to the Gilbert adjustable arm by a round cord belt similar to that used on the foot engine.

The reversing foot-switch is fitted with forward and backward movement, and also instantaneous stop attachment, when the motor is running in either direction. The rheostat is equipped with two sets of binding posts, one of them being for the motor connection, and the other for attaching an electric plugger, mouth lamp, hot-air syringe, or electro-cautery, as may be required, it being so constructed that it will regulate the current perfectly for all these various devices.

The Gilbert wall bracket has an adjustable movement which enables it to be raised or lowered through an angle of 30 degrees, thereby avoiding the necessity of raising or lowering the chair. It has also an extension movement of about twelve

inches which can further be used as a belt tightener. The upright socket at the end of this wall bracket is of the standard size to enable any S. S. White engine head to fit into it without alteration. The engine head can therefore be removed at will from the foot engine, and attached to the electric engine without a moment's delay. This bracket is elegantly finished throughout in polished nickel, and is of handsome design.

ERICKSON OUTLET INSULATOR FOR IRON CONDUITS.

THE general adoption of iron and steel armored conduits for interior wiring of fireproof buildings has led to many improvements in the perfecting of specialties in connection therewith. Prominent among these is the Erickson outlet insulator,

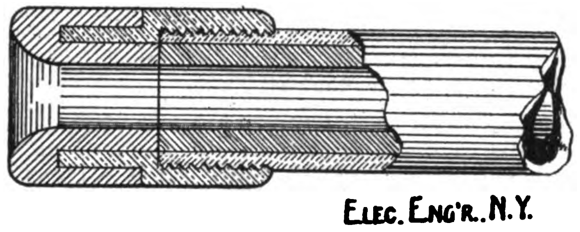


FIG. 1.—THE ERICKSON OUTLET INSULATOR FOR IRON CONDUITS.

handled by the Lord Electric Company, of 181 Tremont street, Boston, Mass.

The outlet insulator, shown in section in Fig. 1, consists essentially of a metal nozzle, tapped at one end to receive the conduit. The other end is encased in a molded insulating shell or armor which forms a finishing terminal for the emergence of the wires from the conduits.

In Fig. 2 an approved method of outlet construction is shown. It will be seen that only the insulating portion projects beyond the plaster line, in which case there is perfect immunity from grounding of the wires or canopy on the conduit armor.

The many possibilities of grounds and short circuits due to

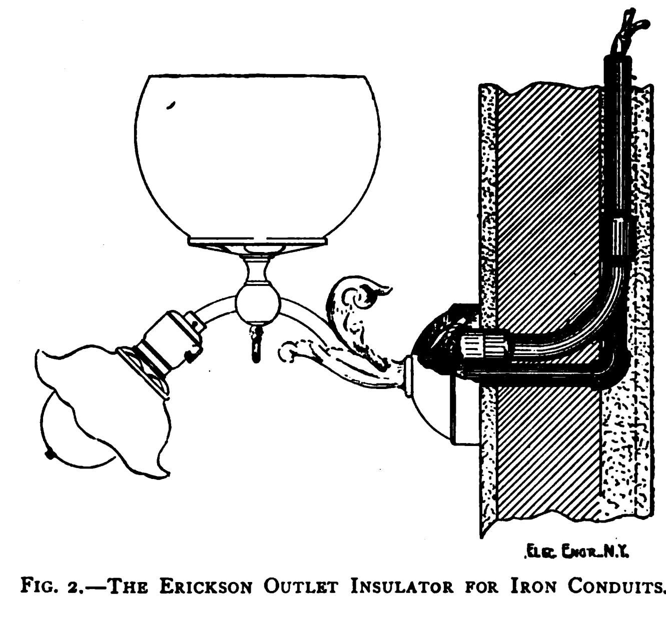

FIG. 2.—THE ERICKSON OUTLET INSULATOR FOR IRON CONDUITS.

the abrasion of the insulation of the wires by burrs at the ends of the conduits make this device an invaluable adjunct to conduit work. Engineers and contractors will readily appreciate the advantage of this appliance in installations under their supervision, where only first-class work is tolerated.

H. W. JOHNS MANUFACTURING CO.

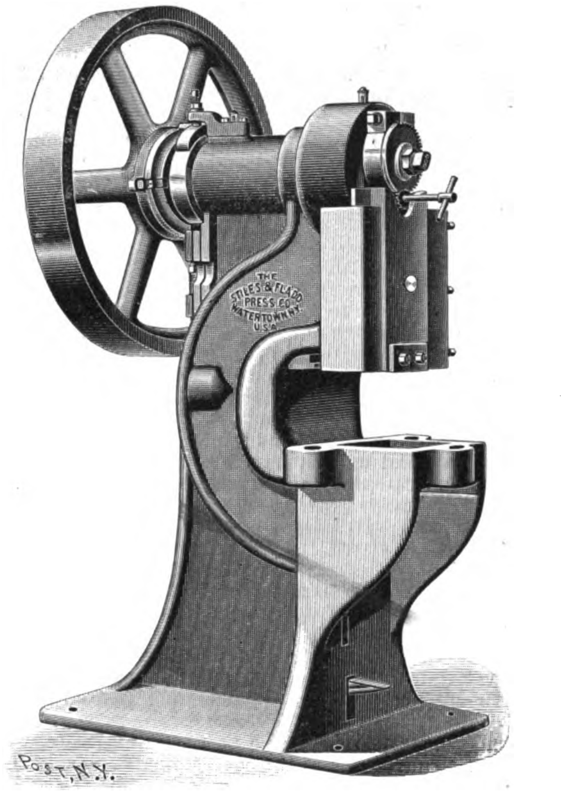
We are in receipt of the June catalogue of electrical materials issued by the H. W. Johns Manufacturing Company, in which they call particular attention to their new electric street car heater. The heater is durable in construction and economical in operation. The wires are not liable to oxidation, as they are protected from the atmosphere by a covering of asbestos which also forms a complete electrical insulation for them.

The wire after being wound with an asbestos thread is woven into cloth with an asbestos warp. A piece of this cloth containing a required amount of wire is fastened with fireproof insulating cement to a sheet of asbestos millboard, which forms its support. The whole is then covered in a case of perforated steel plate which is japanned with an insulating compound.

These heaters admit a free circulation of air through and under the perforated plate, the latter being arranged so that the back of the heater is half an inch in front of the panels below the seat. The heaters are controlled by a knife switch which can be adjusted to give three degrees of heat.

STILES & FLADD PRESSES.

The accompanying illustration shows a press of the improved type manufactured by the Stiles & Fladd Press Company, of Watertown, N. Y. In the construction and design of these punching presses every strain has been carefully considered, and the metal is so disposed as to best resist these strains and at the same time to provide for a limit of safety. Only a special mixture of iron is used in the castings of these presses, and this mixture is constantly tested so as to keep it up to the established standard. All the parts where wear occurs are care-



STILES & FLADD POWER PRESS.

fully scraped to fit exactly, thus providing perfect bearing surfaces.

The special feature to which attention is directed in this press is the clutch, which is a recent improvement upon the original Stiles clutch. This makes it possible to run the press in either direction equally well, and as the clutch acts practically instantaneously it leaves it within the power of the operator to make a whole or only a part revolution of the press which is a valuablue feature in preventing accidents both to tools and operators.

The presses are made in eleven different sizes, the six smaller sizes being fly presses and the five larger ones geared. They can all be readily adapted to electric driving.

NAVY ELECTRICAL SUPPLIES.

The Navy Department, through the Bureau of Supplies and Accounts, is inviting proposals until June 20 for furnishing the New York Navy Yard with one moderate speed dynamo, and other electrical apparatus and supplies for the New York Navy Yard.

ERIE CITY IRON WORKS.

The widespread development in electrical work has given rise to a marked tendency to specialization in the manufacture of steam plants. Prominent among the firms which now concentrate themselves mainly on the turning out of powerful

steam outfits for central station and other electrical purposes, is the Erie City Iron Works, Erie, Pa., and that their experience in this branch of work is appreciated in the trade is shown by the many large and important equipments they are credited with having made. Their specialties are high speed Corliss automatic, high speed single valve automatic, and medium speed single valve automatic engines, as well as Caldwell water tube boilers, and all styles of fire tube boilers. These are made of every desired dimension and power.

I-T-E CIRCUIT BREAKERS.

The Cutter Electrical and Manufacturing Company, 1112 Sansom street, Philadelphia, are sending their friends a handsomely illustrated catalogue descriptive of the I-T-E automatic magnetic circuit breakers for railway, light and power switchboards, motor cars, motors, house service and storage batteries. These are made for both direct and alternating current circuits. The electromagnet of the circuit breaker is designed to develop more energy than is merely needed to trip the retaining catch, this additional energy being employed to aid in opening the main switch. This makes a very quick and positive opening of the main switch when it approaches a condition of short circuit. The time of opening the circuit becomes smaller and smaller as the conditions approach more nearly a short circuit. The opening of the circuit breaker is positive in its action, and the adjustment is regulated by the use of weights and fixed distances, springs being entirely avoided as unreliable. They have ample carrying capacity and excellent provision is furnished for the line connections.

THE DODGE COAL STORAGE SYSTEM ON THE ERIE RAILROAD.

The Erie Railroad Company, after careful investigation and the consideration of a number of plans, have contracted with the Dodge Coal Storage Company, of Philadelphia, Pa., for a 150,000 ton storage plant at East Buffalo, N. Y. The coal will be stocked in nine divisions or piles, each of about 17,000 tons capacity. The plant will be constructed under the patents of the well-known Dodge system, with the latest improvements, including a complete haulage system for handling the cars. The efficiency of the Dodge system is demonstrated by the fact that every railroad using it has contracted for a second plant after more or less extended experience with the first.

ELECTRIC CAR LIGHTING FROM THE CAR AXLE.

THE National Electric Car Lighting Company, 34 Broad street, New York, have so far interested the Pennsylvania Railroad Company in their new method of car lighting as to now have a practical test made by the latter company on their cars, which leave New York for Philadelphia at 4 p. m., also on the well-known "Owl" train from Philadelphia at 12 midnight. Briefly described, the mechanism and power employed by this company to produce 14 to 16 candle-power electric lights in railroad trains is located and produced entirely on the truck of the car. The power is derived from the revolution of the car axles. Storage batteries, which are charged for five hours, but can run for twelve, are also placed on the truck.

Thus far, 4,000 miles have been covered by cars with this system of electric car lighting, and we are informed by Mr. Max E. Schmidt, of the National Electric Car Lighting Company, that the lighting system is coming up to the entire expectations of both parties concerned.

NEW YORK NOTES.

MR. H. ALEX. HIBBARD, dealer in electrical supplies, at 621 Broadway, has associated with him Mr. Otis Sheldon, and the business will be conducted hereafter under the firm name of Hibbard & Sheldon.

W. D. FORBES & CO., 304 Hudson street, Hoboken, N. J., are running their factory night and day, turning out large orders for machinery and specialties, such as high-speed engines for dynamo driving, milling machines, and other machine tools.

MR. NORMAN HUBBARD, 93 to 97 Pearl street, Brooklyn, N. Y., has good orders for his vacuum pumps, which he manufactures for incandescent lamp exhaustion, and is busy on a contract which has been awarded him for a part of the iron work on the new extension of the Brooklyn Bridge.

THE CHESLEY ELECTRIC COMPANY, 601-605 Newark street, Hoboken, N. J., are facilitating their work by putting in new boilers and engines. They are quite busy on general repair work and report satisfactory sales in second-hand electric machinery, which is their specialty. This firm has a New York office in the Havemeyer Building.

DALE, FARRELL & CO., of 413 East 25th street, are busy at work with a force of fifty-eight men, making up their "Volto" battery, bicycle lamp, magneto bells, car fenders, bicycles, etc., Lack of material for certain parts prevents them from delivering the large orders received for some of their goods. Mr. Dale reports as soon as these delayed adjuncts can be procured the factory will probably be worked to its fullest capacity with a force of from 200 to 300 men.

STUCKY & HECK, 35 New Jersey Railroad avenue, Newark, N. J., have recently received an order for thirty railway armatures, and with their splendidly equipped factory and a force of about forty hands are kept busy turning these out, as well as doing a large amount of repair work, their principal business. This firm works only on orders and has special facilities for turning out goods at short notice. Transformer work, commutators, new armatures for lighting machines and the like are their specialties.

JACOB BROMBACHER & SONS, 31 and 33 Fulton street, Brooklyn, N. Y., have for the past six months put on the market their improved gas engine to be used in conjunction with the Excelsior dynamo, which is giving excellent satisfaction. It runs 100 sixteen candle-power incandescent lamps at full wattage, and at an average cost of not more than 25 cents per hour. The voltmeter does not vary over two volts. This firm exhibit the workings of the entire plant, including meters, from 3 to 6 p. m. daily.

THE SUTTON MICROPHONE TRANSMITTER, illustrated in our issue of last week, has been assigned to the Phoenix Interior Telephone Company, of 157 Greenwich street. This is the granular carbon transmitter with which they have been so successful during the past few months and upon which letters patent have just been issued. These transmitters are guaranteed not to pack; in fact, the company will repack free of charge all transmitters which at the end of a year's service deteriorate or are any different from the day they were put up.

MR. L. W. KINGSLEY, secretary of the Mica Insulator Company, 218 Water street, New York, sailed June 3, on the steamship St. Louis, for a trip abroad, where he will spend considerable time in sight-seeing, as well as looking after the affairs of the company in Europe. The company's business is largely increasing in foreign countries, which is due to the high grade of insulation "micanite" they are furnishing the manufacturers of electrical machinery of the European countries, from their newly equipped factory, which is located at Stoke Newington, London. Upward of 100 hands are given employment. The company's London office is at 12 Camomile street.

WESTERN NOTES.

TACOMA, WASH.—The Central Electric Manufacturing Company, of Tacoma, has been organized, with a capital stock of $50,000. The incorporators are E. E. Salisbury, A. E. Dean and others.

THE NUTTING ELECTRIC COMPANY, of Chicago, are in bad shape, and in behalf of the Morgan & Wright Company the Chicago Title and Trust Company has filed its acceptance as receiver for the concern.

BOWERS BROTHERS, Lake street, Chicago, have just received a handsome medal and diploma awarded by the World's Columbian Exposition. The award is made for the pureness, transparency, and superior quality of the mica, which they exhibited at the World's Fair.

THE MASON ELECTRIC EQUIPMENT COMPANY, Chicago, who are agents in that territory for the Fiberite Company, Mechanicville, N. Y., and the Lafayette Engineering and Electric Works, Lafayette, Ind., have removed their offices from No. 307 Dearborn street to No. 1202 the new Fisher building, Dearborn and Van Buren streets, Chicago.

THE C & C ELECTRIC COMPANY have opened a branch at 311 Dearborn street, Chicago, where they have secured a fine show room and office, and it is their intention to keep a considerable stock of their well-known dynamos and motors always on hand. Mr. J. Holt Gates will look after their interests at the Chicago end, and hopes to secure a good share of the Western trade.

THE ELECTRIC APPLIANCE COMPANY are meeting with considerable success in the use of Packard Mogul lamps for lighting parks and summer gardens. One of Chicago's largest pleasure resorts of this kind, Fisher's Garden, near Lincoln Park, has been lighted entirely with Packard Mogul lamps for two seasons with such success that the Electric Appliance Company are making special efforts to extend the use of the Mogul lamps for this class of work.

Department News Items will be found in advertising pages.

THE
Electrical Engineer.

Vol. XXI. JUNE 24, 1896. No. 425.

ELECTRIC TRANSPORTATION.

THE JOHNSON-LUNDELL RAILWAY SYSTEM.

OF the various methods of electric street car propulsion which have been exploited, the overhead trolley, the underground trolley, the storage battery and the surface contact, the latter has received the least attention of any, although in some of its aspects it presents advantages which none of the other methods can claim. The general plan of picking up the current from points on the surface of the road which are alive only during the time the car passes over them, has been studied by many inventors during the past ten or fifteen years, but up to the present time but little that has proved practical has been achieved.

A good working example of the surface contact system invented by Messrs. E. H. Johnson and Robert Lundell, has been in operation on West Thirty-fourth street, New York, for about four months and embodies some novel and important points in its construction. The road, illustrated in Fig. 1, extends from Tenth avenue west to the Hudson River, a distance of about one-third of a mile, is double track, or exactly 3,540 feet of single track. There are 148 manholes or switch boxes alongside of the tracks, each manhole containing two switch magnets.

In order to follow the operation of the system the reader is referred to the diagram, Fig. 2, which shows the connections of circuits and working parts. A storage battery, B, consisting of 200 cells, of small capacity, is divided into halves and placed under both ends of the car beneath the floor. This battery is used on starting the car only, except when it may be

FIG. 1.—VIEW OF JOHNSON-LUNDELL CAR AND TRACK, NEW YORK.

called into use by some emergency, such as the crossing of steam railways, etc. Its main function, however, is to start the switch magnets when the car is standing still and the switch magnets are all open.

Suppose the car to be situated as in Fig. 2, and that the motorman starts it by closing the switch Sw. The current will then flow from the positive pole of the battery through wire w^{11} to switch Sw, through resistances and conductor w^{10},

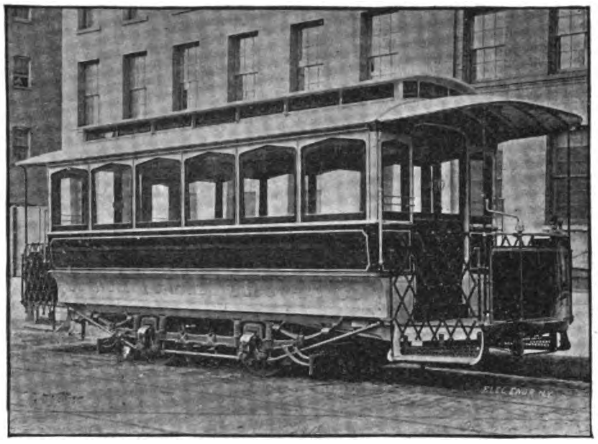


FIG. 3.—JOHNSON-LUNDELL ELECTRIC CAR.

through the motor M and wire w^{12} to contact-shoe S^2 and thence to sectional trolley-conductor Sc^4; thence by wire w^4 through a coil around the switch-magnet M^2, and also through a coil around switch-magnet M^3, energizing these two magnets, and finally to track-rails R and R′, car-wheels, and negative pole of the battery.

This battery current is sufficient to start the car under way, but its main function is to move the switch levers, p^2 and p^3, which close the connections between the branch feeders, Fw^2, Fw^3, and the sectional trolley conductors, Sc^3 and Sc^5. In this position of the switch magnets, which are closed by the battery current, the line current passes up over the line, w^3, to the contact shoe S′ and through the wire, w^9 to the switch Sw, at which the current is divided into two parallel circuits. One of these circuits passes through the line w^{11} to the battery, which it charges, as the line circuit is of a higher potential than the battery circuit. From the battery the charging current passes through the wire w^{13} to the car axle, and then to the track which forms the return circuit.

The other parallel circuit from the switch Sw carries the line current through the wire w^{10} to the motor M, then through wire w^{12} to contact shoe S_2. From this contact shoe the current is conducted by Sc^4 through wire w^4 to the coils of the magnets M^2 and M^3 in the same directions as before, and from M^3 it passes to the track return, R R′, completing the circuit.

It will thus be seen that the coils of the magnets M^2 and M^3 are in series with the motor M, and that in consequence the switch-levers p^2 and p^3 will remain closed as long as the propelling current flows through conductor w^4.

If the car be moving from right to left, it will be evident at a glance that the sectional conductors Sc^5 and Cc^7 are made alive in advance of the contact-shoe S′; but it remains to be seen if this holds true when running in the opposite direction. Suppose the car starts from the position shown and moves to the right instead of to the left. All connections will then remain undisturbed as long as the contact-shoe S^2 is still upon the sectional conductor Sc^4; but when the shoe S^2 closes contact with sectional conductor Sc^3 and finally breaks contact at Sc^4 the propelling current will simply be shifted from wire w^4 to wire w^2. This, however, energizes magnet M′ instead of magnet M^3, and magnet M^2 remains undisturbed, leaving the branch feeder Fw^2 in connection with Sc^3. As the shoe S′ now approaches sectional conductor Sc′, the lever p′ will have closed connection between the branch feeder Fw′ and the sectional

conductor Sc', thus illustrating that the system of interconnections between switch-magnets is adapted to work both ways.

It will be apparent from an inspection of the diagram, Fig. 2, that the maximum time allowed for each magnet to close is equal to the time the car takes to travel the distance between the sectional conductors Sc^2 and Sc'. It will also be noted that the high-potential sectional conductors Sc', Sc^2, Sc^3, and Sc' are in direct connection with the contacts l', l^2, l^3, and l' in the switch-boxes without any of the coils around the magnets being included in circuit, so that in case the insulation o. one of these sectional conductors should become impaired, the leakage-current cannot hold the magnet closed and therefore cannot keep the conductor alive after the car has passed.

On the experimental road in Thirty-fourth street the line current has a potential of 500 volts and the car, Fig. 3, contains 200 cells of accumulators, which allows the latter to be charged at their maximum rate of 2½ volts per cell.

The location of the surface contacts is shown in Figs. 4 and 5, which are reproductions of photographs taken while the roadbed was under construction. The former illustration shows these castiron contacts standing upon a block of insulating material and fastened on top of the ties by lag screws, which are insulated from the contact column. Fig. 5 shows the same view, taken after the contacts were surrounded by a covering of rock asphalt except upon the top surface, where contact with the skates S' S^2 is made. They are placed in the roadbed with their upper contact-surfaces slightly higher than the pavement. To minimize leakage in wet weather they are made as short as possible, and to prevent any sectional conductor from being alive in front of or after the car they are placed at such distances apart that the platforms of the car will safely cover both the conductor which is doing service and the one which is made ready for service.

The battery, as stated above, is of an electromotive force approximating that of the line, so that it will always be fully charged and ready to do service when called upon. It may also be of such capacity as to be able to propel the car for short distances across turnouts, crossings, switches, etc., where the electric equipment of the roadbed would present natural difficulties. The battery will thus propel the car independently of the station current by closing the switch Sw and also another switch, not shown, which is placed on the center of the car platform and which closes a connection between the wires w^{12} and w^{13}. This switch may also be arranged to break the connection between the switch Sw and the contact shoe S'.

At Eleventh avenue the road crosses the tracks of the New York Central Railroad and at this point the electrical equipment is interrupted and the car either crosses simply by momentum or by means of the storage batteries. On the 3½ per cent. grade between Tenth and Eleventh avenues the electrical contact equipment is also omitted on the down grade side of the tracks. All the current necessary at this place is that which may be required to start the car, and this is supplied by the battery. In any case, after starting, the current would have to be turned off and the brakes applied, so where the grade is sufficient it is not necessary to equip the track with the contact system, as the battery is sufficient to meet all the demands for starting.

Fig. 6 shows two separate views of the switch magnets represented by M in the diagram, Fig. 2, and also the sectional conductor or contact piece. The coil in the center is the double winding by means of which the inter-connections of the switch magnets explained above are accomplished. The two rows of spring contacts on either side of the switch are connected by means of the carbon block which lies beneath and between them. The carbon block, as it appears in the lower figure of the illustration, is raised by the magnet to which it is attached against the springs when the current passes around the outside magnet frame. The switch acts instantly and positively and is held in position with as much force as a man can conveniently overcome with one hand. When the current is cut off the magnet the carbon bridge drops down instantly upon its seat, in the position shown in the upper view of the switch

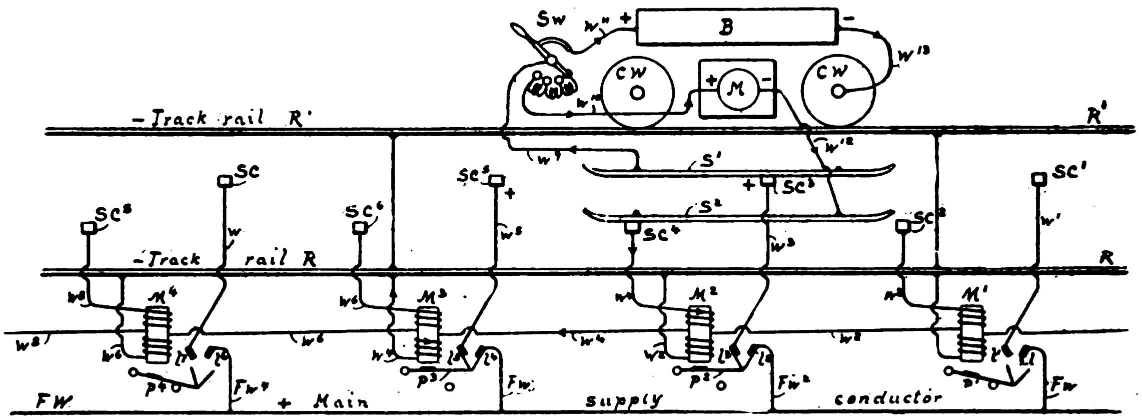

FIG. 2.—DIAGRAM OF CIRCUITS OF JOHNSON-LUNDELL SURFACE CONTACT STREET RAILWAY SYSTEM.

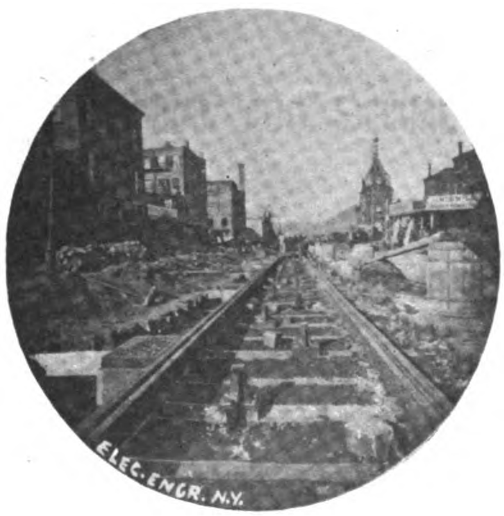

FIG. 4.—VIEW OF TRACK, SHOWING CONTACT PILLARS.

FIG. 5.—VIEW OF TRACK, SHOWING CONTACT PILLARS ENCLOSED IN ASPHALT.

magnet, without any signs of arcing. In placing these switches along the track they are put in manholes which are several inches deeper than the height of the switches. These manholes contain four pillars, upon which the switches stand, which raise them up near the top of the manhole boxes. They are then covered with a box in the form of a diving bell, so that no water or drainage can reach its upper part where the switch is located. The moisture cannot affect the movable part of the switch, as it is extremely loose fitting and is covered with a sheathing of brass to avoid any difficulty from corrosion.

When no car is running, and consequently no contact points are alive, there is absolutely no leakage possible on the system in any kind of weather, owing to the high insulation of the main conductor and switch magnets. There is also no leakage in dry weather when the cars are running. It is readily seen that when any leakage does occur it can only be at the point directly under a car where the contacts are alive.

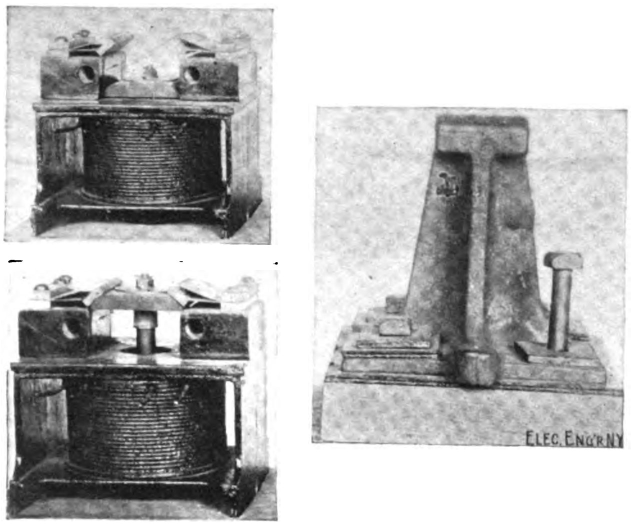

FIG. 6.—JOHNSON-LUNDELL SWITCH MAGNET AND CONTACT PILLAR.

During a rain storm, or immediately after, the leakage from a positive contact point is about ¼ ampere and from the whole contact bar about one ampere. The greatest leakage appears to be due to snow and slush during the winter, but no accurate data could be secured owing to the difficulty of taking readings while the car was running on a crowded street. On the day after a heavy snow storm when the track rails and contact points were entirely submerged in water and snow the leakage from the positive contact bar appeared to be only from 3 to 5 amperes.

A NEW TROLLEY ROUTE FROM WASHINGTON, D. C.

The interurban trolley line between Washington and Mount Vernon was recently opened for traffic as far as Arlington. The line is run somewhat on the plan of the ordinary suburban steam road, the trains consisting of three long cars equipped with airbrakes, compressed-air whistle, signal lanterns, green flags at the end, and all the paraphernalia of a regular steam road.

The cars will not stop anywhere and everywhere; passengers are required to buy their tickets at the stations, and in case they pay on board they are charged an extra fare, and given a rebate check of the conventional pattern. The route selected winds its way through rather obscure city streets, where the underground trolley is used, until it reaches the Long Bridge. Here the overhead trolley comes into play. The electric trains are switched directly on to the bridge tracks of the Pennsylvania Railroad, over which they run for a considerable distance. A railroad of the same kind as the Mount Vernon Road is now in process of construction between Washington and Baltimore, and this in turn is said to be but a part of a plan for eventually connecting the four great cities, New York, Philadelphia, Baltimore and Washington.

THE DUBLIN TRAMWAY 3-PHASE TRANSMISSION.

We illustrate herewith the sub-station switchboard connections of the Dublin tramway system, which our readers will remember was described at length in The Electrical Engineer of February 5, 1896. This station is of interest from the fact it is among the first to make use of a three-phase transmission for street railway work. The three-phase current, however, is not utilized directly to drive the cars, but is led to two transformer sub-stations, at Blackrock and at Dalkey, the former being 6,000, and the latter 12,600 yards from the generating station. At these points the three-phase current drives synchronous motors which in turn drive direct connected, 500 volt generators which feed into the trolley line. The diagram of connections shown is that of the Blackrock sub-station, and it differs very little in its general arrangements from that in Dalkey except as to the size of the units employed. This plant is composed of two direct coupled units, each consisting of a synchronous motor coupled direct to a 60 kilowatt direct current generator. The motor is run with a 2,300 volt three-phase current and the generator produces current at from 500 to 550 volts.

It will be seen that the three-phase mains are first connected to three-pole 50 ampere switches and from thence the current passes to the three-phase bus-bars. From the bus-bars connections are made to the various instruments and to the switches to the motors. It is necessary that the motors which

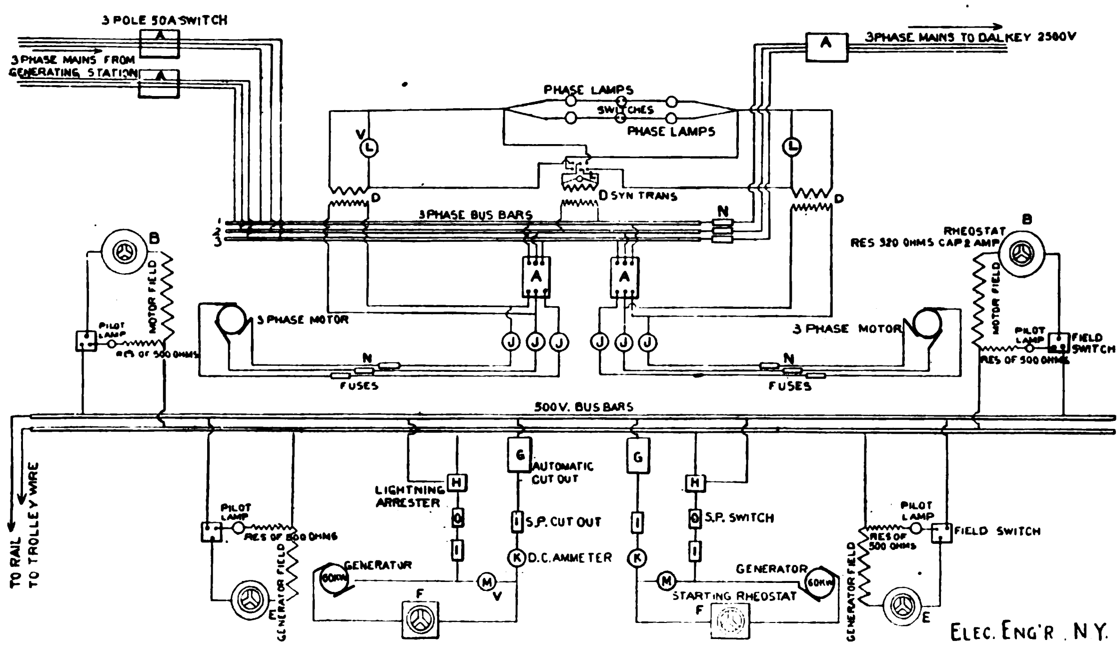

DIAGRAM OF CONNECTIONS OF DUBLIN-DALKEY THREE-PHASE RAILWAY SYSTEM.

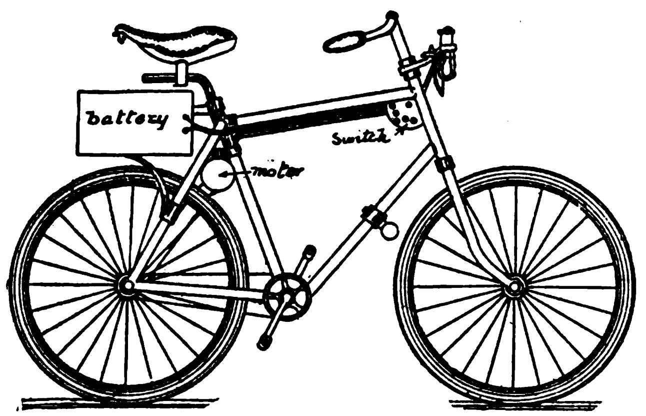
drive the railway generators are not thrown on to the three-phase mains before they have arrived at synchronism. For the purpose of speeding them up, therefore, arrangements are made for diverting current from the trolley wire to the generator, thus causing it to run as a motor for a short time, and speeding up the real motor till it is in synchronism with the three-phase system. In addition there are on the switchboard switches for controlling the entry of the three-phase current, and the machines switching gear for the 500 volt circuits.

AN ELECTRIC BICYCLE.

THE latest innovation in the manufacture of bicycles is an electric motor attachment, the invention of Mr. James O'Brien, of New York City. The accompanying illustration shows the attachment, which supplies motive power for the bicycle and current for the electric headlight. The wheel is of the ordinary pattern and weighs twenty-seven pounds without the electrical attachment. With the latter the total weight is brought up to sixty lbs. The elecrical equipment consists of a battery, motor and switch. The battery is a dry chloride cell and its weight is about fifteen lbs.

From the illustration it will be seen that the electric attach-



AN ELECTRIC BICYCLE.

ments occupy comparatively little space. They can be easily detached, and the machine can be used in the ordinary way. Should the battery or any part fail, it is not necessary to remove these parts. If at any time the rider wishes to use the pedals instead of the electric power, a small switch will cut off the current.

The switch is placed in the illustration below the bar, but the inventor's latest improvement places it under the handle, so that it can be reached without trouble by the rider. A woven silk band is used to connect the motor with the hub of the rear wheel.

ELECTRIC RAILWAY EXTENSION IN CHICAGO.

Two hundred and twenty-five miles of electric road have been projected to haul Chicagoans to summer resorts in the torrid season and bring Wisconsin ice to Chicago. The deeds for the right of way from Evanston to Wilmot, Wis., are in the vaults of the Chicago and Inland Lakes Railway.

Besides touching eighty-one lakes and coming near a score of others, it is planned that branches of this newest venture in Chicago railroad building will touch Madison, Milwaukee and Lake Geneva. The road will traverse three counties in Illinois and seven in Wisconsin, and will at no point be less than two miles and at most points ten miles from competing roads. The officers of the company are: Alfred E. Case, president; S. Marcus Rothschild, vice-president; G. D. Green, secretary; F. Boden, treasurer, and A. J. Toolen, general manager.

CYCLING BY TROLLEY POWER.

Three cyclers riding abreast of a street car made a scene on Genesee street last evening shortly before 8 o'clock. The car was pacing the wheelmen at a speedy clip, and, partly to make the rate of progress uniform and more to produce the aforementioned scene, one wheelman laid his left hand on the car, and each of the other two boys put his left hand on his neighbor's right shoulder. The dynamo at the power house did the rest.—Buffalo "Courier."

POWER TRANSMISSION.

FORT WAYNE SINGLE-PHASE ALTERNATING MOTORS.

BY THOMAS A. NATHANS.

AMONG the interesting pieces of apparatus at the recent Electrical Exhibition were the single-phase alternating current power motors exhibited by the Fort Wayne Electric Corporation. These motors are strictly single-phase machines,

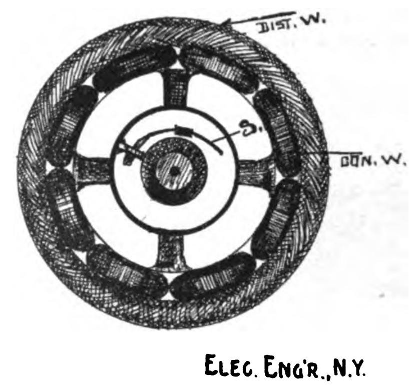


FIG. 1.—ARMATURE WINDINGS OF FORT WAYNE ALTERNATING MOTOR.

starting under full load without the aid of external apparatus, such as condensers, phase-splitting devices, etc. Running as synchronous motors and capable of being used as rotary transformers, they give to the single-phase alternating system every

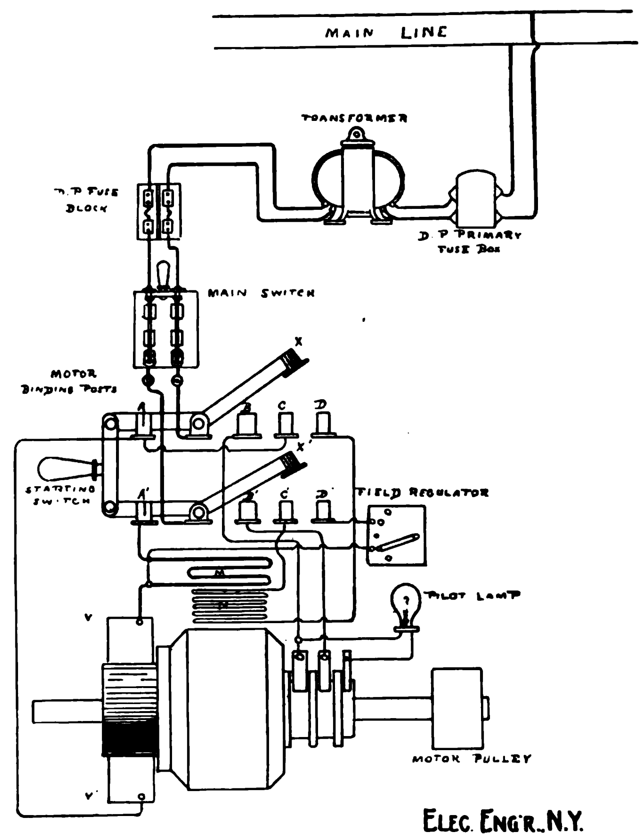

FIG. 2.—DIAGRAM OF CONNECTIONS, FORT WAYNE ALTERNATING MOTOR.

advantage of the low tension direct system with the additional ones of flexibility, and adaptability to long distance transmission.

The machines are strikingly simple, compact and durable. The armature is of the ring type, and carries two windings, one

a distributed winding, wound in the teeth on the periphery and connected to a commutator, which is placed on one end of the shaft; the other winding is a concentrated one, having as many coils as there are field poles, and connected to two collectors at the other end of the shaft. The relative position of these windings is shown in Fig. 1. The multipolar field is well laminated and resembles that of a large alternating current generator; it is also wound with two windings, one, a few turns of heavy wire, and the other a deep winding of fine wire. A double throw lever switch and a pilot lamp, both situated on top of the machine, complete its simple appearance.

By following the connections in diagram, Fig. 2, its small number of parts and practical construction will be clearly seen. Instead of the introduction of a phase shifting, transforming device, or choke coils, the secondary of an ordinary lighting transformer is connected to the binding post of the double throw switch after passing through the fuse box and main switch.

When the machine is not in use the starting switch is left so

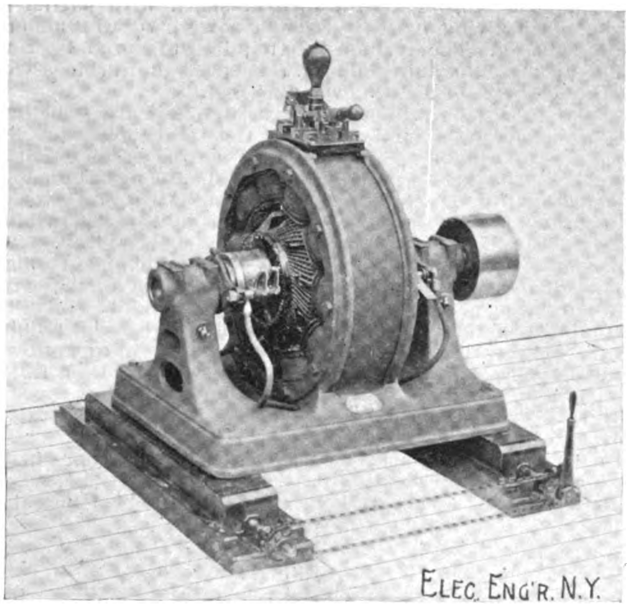

Fig. 3.—The Fort Wayne Synchronous Alternating Motor.

that neither of the lever arms engages with the connecting clips, AA′, BB′, CC′, DD′.

In starting, the handle of the starting switch is depressed, thus connecting the clips A and A′ to the circuit; the current is thus carried to the commutator end, then passes through the distributed winding of the armature, through the heavy winding of the field, M, and back to the source of supply. In other words, the machine is a simple series motor at the start, and with proper winding on the field it is well known that it will start up with a powerful torque. No rheostat is used in starting, as the self-induction of the field coils prevents an inrush of current, which would otherwise damage the machine. The motor starts under full load and rapidly speeds up.

Referring to the diagram, a small third collector ring is placed beyond the two regular ones, and beneath this auxiliary collector is placed a centrifugal spring, shown at S, Fig. 1, which is so adjusted by a sliding weight that it will make contact with the inside of the collector when the speed of the armature is a little higher than is needed for synchronism.

One of the terminals of the concentrated winding is connected to the inside collector, and the other is branched and is connected to the second collector and the standard that holds the centrifugal spring under the third collector. Hence, when the spring makes contact with the auxiliary collector, the pilot lamp on top, which is now connected between the first and third collectors, lights up at a dull red, due to the alternating e. m. f. induced in the concentrated winding from the distributed winding through which an alternating current is flowing. The lighting of the lamp is a signal to throw the switch. The switch is then raised, breaking the connection at the clips A and A′, and making two connections on the other side. First B and B′ are connected with the switch blades, and second the small bars X and X′, which are insulated from the blades, connect C with D and C′ with D′; the first connection feeds the alternating current from the transformer to the collectors, and the second closes a circuit from the commutator end, which was just filling the office of an alternating motor, but now that of a continuous current generator, through the fine winding of the field. The current starts, say, from brush Y′, going from C to D, through the fine winding, through C′ and D′ through a small rheostat, and back to brush Y. The motor now is connected up as a synchronous machine; its speed decreases a little until it falls into step with the generator. As the speed drops, the spring under the third collector breaks the circuit through the lamp and it goes out.

The rheostat is placed in the base of the machine, its handle being accessible through an oval opening on the commutator end. The object of this rheostat is to regulate the field excitation and it is set at the factory.

In starting with no load the time taken for the motor to reach synchronous speed is from five to fifteen seconds, depending upon the winding, and, when loaded, from fifteen to thirty seconds, depending upon the load. The current used at these times is from 25 to 50 per cent. in excess of what the machine requires when running in synchronism.

The motor can be adjusted for any starting torque by changing the heavy winding, and in case only a small torque is required at the start, as in running countershafting where the machines are thrown on independently, the required starting current is greatly reduced.

In spite of its simplicity, the machine may be used in a variety of ways. As a rotary transformer it can be used as a shunt motor, the speed of which can be varied by a rheostat, and alternating currents of any frequency can be taken from the collectors; or it may be run by an alternating current while a direct current is taken from the commutator. If the machine be driven from its pulley it may be used as a self-exciting alternator, and it may also be driven as a series motor by a direct current.

THE UTILIZATION OF WATER-POWER, ESPECIALLY WITH A SMALL FALL, WITH SOME EXAMPLES OF PLANT FOR THE GENERATION OF ELECTRICAL ENERGY.[1]—I.

BY ALPH. STEIGER.

THE cheap production of electrical energy is generally recognized to be one of the chief aims of modern engineering science. Nature has provided us in water-power with one of the best possible agents for realizing this object; and I trust that, in bringing the subject of the utilization of this free gift of nature before the members of the Institution of Electrical Engineers, I shall be able to convince them that the water-

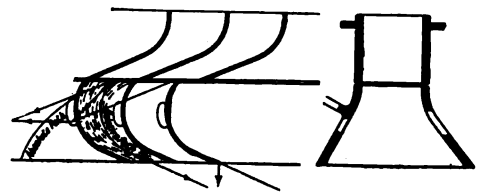

Fig. 1.—Vanes of "Action" Turbines.

powers of this country, if judiciously utilized, are capable of rendering them great service.

In my own country—Switzerland—the electrical engineer is co-operating cordially with the water-power engineer, and electrical installations are rapidly increasing in number. The successful electrical transmission of power to points far distant

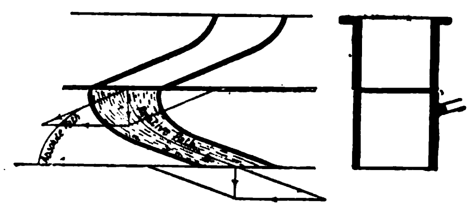

Fig. 2.—Vanes of "Reaction" Turbine.

from its source has been the chief factor in this development. The idea prevails that considerable fall is required to obtain water-power, but it is my desire to show and to prove in the following remarks that excellent results are obtainable also with a very low fall—a fall of even less than three feet. Small falls are more frequently met with in this country than high falls

1 Paper read before the London Institution of Electrical Engineers.

and will therefore have more particular attention in this paper than the high falls found in mountainous districts. The description of a few turbine plants under low falls, some of which are applied to the generation of electrical energy, will be of special interest.

During a long experience in constructing turbines and designing complete plants I have found that the most difficult were

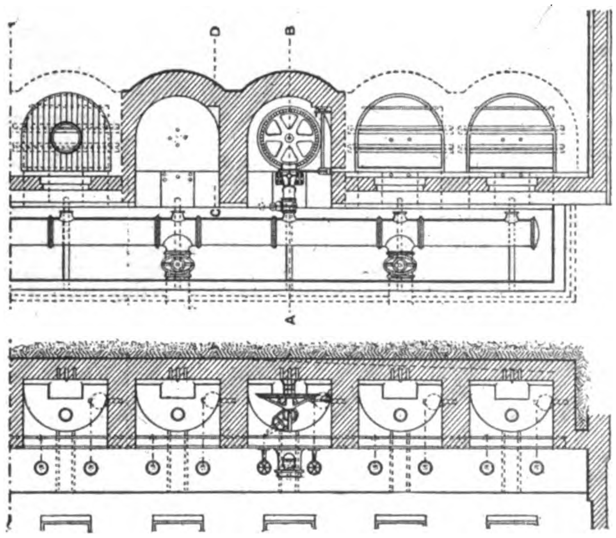

FIG. 3A.—TURBINES AT THE FALLS OF FOYERS, SCOTLAND.

always those connected with the utilization of a low fall. These difficulties consist chiefly in the variation within very wide limits of both the quantity of water and the fall, while a constant power, and in most cases a constant speed, is of great importance.

Generally speaking, the real agent in water power is gravity, and the water is simply the medium to transmit the action of gravity on to the motor which converts it into mechanical work. The action of gravity can take either the form of dead weight, or of pressure, or of velocity, sometimes called kinetic energy. A very high efficiency is obtained from motors in which the water acts by dead weight or by pressure, but the slow speed of the water wheels and the complicated mechanism of the pressure engines render them unsuitable for the purpose of generating electricity; moreover, motors worked by weight or by pressure are only advantageous when working under a high fall. The kinetic energy is the only form in which the gravity can be applied advantageously to the performance of mechanical work under a small fall. The motors using it in this form are the common undershot wheel, the Poncelet water-wheel, and the turbines. It will be sufficient for the purpose of this paper to give the efficiency of the various types of water motors for any fall without going into a detailed description of those which are unsuitable for driving dynamos. The efficiency of the motors, with the fall for which they are adapted, is as follows:

Fall. Feet.	Efficiency of water wheel.		Efficiency of turbine.
		Per cent.	Per cent.
1 to 5	Ordinary undershot	25 to 30	70 to 75
	Poncelet	65 to 70	
	Segebien	65 to 75	
5 to 8	Low breast	30 to 50	75 to 80
8 to 15	High breast	60 to 75	75 to 80
15 to 50	Overshot wheel	55 to 75	75 to 80
Above 50	Pressure engine	75 to 85	75 to 80

These figures show the interesting fact, that the smaller the fall is, the greater is the gain in power over the old-fashioned water wheels. Although the smallest fall which would reasonably be utilized by a turbine is at least 2 feet 6 inches, I will show by some examples that, by a turbine suitably constructed and carefully adapted, useful power is still obtained under a fall of only one foot, or a little over. The great variety of fall, water supply, local conditions, and special requirements, of necessity demands a variety of types of turbines.

Turbines are classified, according to the manner in which the water acts in them, into—(a) "impulse," or "action," turbines, and (b) "reaction" turbines; and according to their construction, into—(a) parallel flow turbines, (b) radial flow turbines, (c) mixed flow turbines.

There is an essential difference between the "impulse" turbine and the "reaction" turbine, as indicated by the form of vanes illustrated in the diagrams, Figs. 1 and 2.

The "impulse" turbine, as usually constructed, must run clear of the tail water, its buckets being only partially filled with water. It requires a constant fall, with constant level of the water in the head and tail race, but its efficiency is not affected by the greatest variation of the water supply. On account of this quality, it can be built as partial injection turbine, to utilize high falls with a very small water supply. If constructed as "partial injection turbine," its diameter can be chosen so as to give just the desired number of revolutions. This is extremely convenient for driving dynamos, which can thus be connected direct with the shaft of the turbine, doing away with intermediate gearing or belt drives. An instance of this kind is the turbine plant now being erected by Messrs. Escher, Wyss & Co., of Zurich, at the Falls of Foyers, for the British Aluminum Company (Limited). This plant consists of five "impulse" turbines with vertical shaft, with partial injection, each giving 700 British horse-power, working under a fall of 350 feet. The dynamos are required to run at 140 revolutions per minute, and to obtain this speed the turbines were given a diameter of a little over nine feet.

Partial injection turbines under a high fall are sometimes fixed on a horizontal shaft, and can thus be coupled direct to the armature spindle of a dynamo by means of an isolating coupling. This mode has been adopted, amongst numerous other plants, for the electric lighting installation of Davos, in Switzerland, which consists of three horizontal patent turbines of 200 British horse-power each, working under a fall of 330 feet, and running at 400 revolutions per minute. The turbines have a diameter of forty inches. As a contrast to these turbines of large power and small diameter, and to show the adaptability of the partial injection turbine to special requirements, the 140 horse-power turbines of the waterworks in Chauxdefonds may be mentioned. These work under a fall of only 170 feet, but as they are driving pumps at the low speed of sixty revolutions they had to be made of a diameter of fifteen feet.

Great as the advantages of the "impulse" turbines are under the conditions above mentioned, their use under very low falls is limited, firstly, owing to the reason already given that they

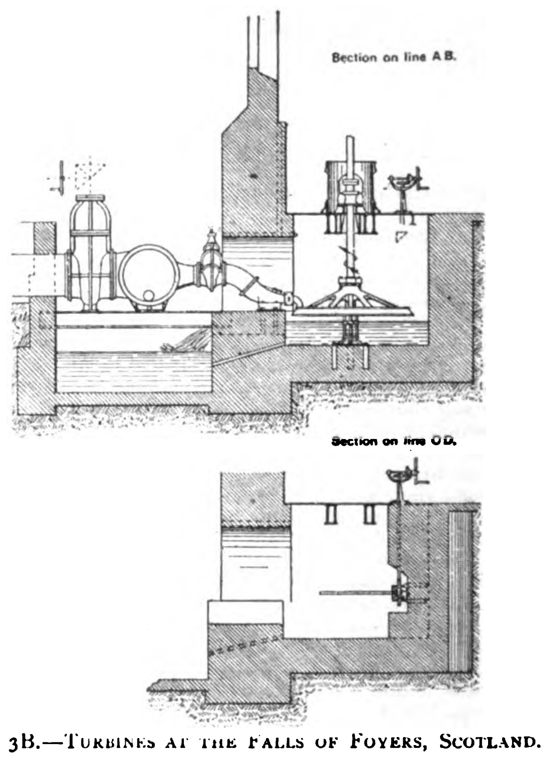

FIG. 3B.—TURBINES AT THE FALLS OF FOYERS, SCOTLAND.

must run clear of the tail water—a condition which can seldom be realized in a flat country like this; and, secondly, because they run at a slower speed than a "reaction" turbine under the same fall. Although "impulse" turbines are now built to run in the tail water without considerable loss of efficiency, the reduction of power in proportion to the reduced fall, and the quantity of water accordingly reduced, together with the reduced speed, excludes them in the majority of low and vary-

ing falls. The ideal turbines for low and varying falls are the "reaction" turbines. They are generally placed on a level with the tail water, or, if local conditions require them to be placed above tail water, connected with it by a suction tube. They run at a higher speed for the same fall, or the same diameter, than an "impulse" turbine, and their efficiency is not affected by the immersion in the tail water. The principal objection raised against "reaction" turbines in general is that their efficiency is greatly reduced when working at part gate. This is indeed the case with many of the reaction turbines known in this country, which give a very poor efficiency at part gate, especially at less than half gate. The continuity of flow of the water through the buckets is essential to a good efficiency. Only in a few reaction turbines is this condition fulfilled to such an extent that within very wide limits of the water supply the efficiency is not perceptibly reduced.

The utilization of a small and varying fall, with a varying quantity of water, is a very difficult problem for the water-

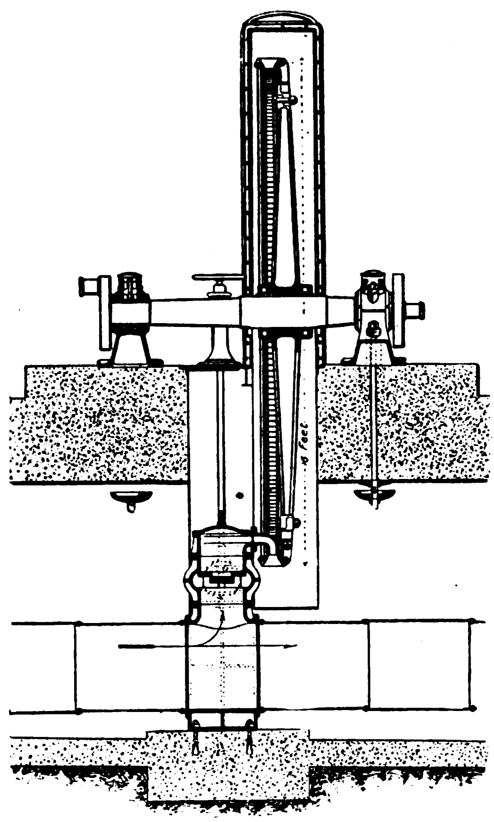

FIG. 4.—TURBINES OF THE CHAUX DE FONDS WATERWORKS, SWITZERLAND.

power engineer. The turbine for a given power under a low fall is larger and runs slower than one of the same power under a higher fall; it is, therefore, heavier and more costly, and requires heavier gearing, entailing a greater loss of power through friction. A high speed is desirable, especially for driving dynamos; but attempts to increase the speed of the turbine by reducing its diameter may easily result in an inferior efficiency. The efficiency should be as high as possible in consideration of the greater cost of a water-power plant with a low fall; but the proportion within which such a fall and the quantity of water varies is mostly so great that it is almost impossible to obtain the highest efficiency when the water supplied is diminished, i. e., when a high efficiency is most wanted. The maintenance of a constant power with a constant speed under variation of fall and quantity of water in large proportion can, if at all, only be attained by sacrificing some efficiency. The hydraulic losses must be reduced to a minimum by the most careful construction of the turbine in its essential parts, and it is needless to say that no standard size or type of turbine will fulfill all these conditions by simply consuming all the available water.

Even the arrangement of the turbine chamber is of influence on the results, and requires special attention. On a careful judgment of the local conditions depend the economy and the success of a plant. Unsatisfactory results in water-power plants are caused just as much, or oftener, by bad judgment of the local conditions as by the inferiority of the turbine.. In by far the most cases of low falls incidental to flat countries, an abundance of water corresponds with a reduction of the fall. The power of a turbine calculated for the normal fall would be reduced, for the time, when an abundance of water reduces it; and, as a consequence, water would be wasted, while the power obtained is insufficient. These cases are, unfortunately, of frequent occurrence. On the other hand, if the turbine is constructed to give off the required power under the reduced fall, it must be partially closed for the diminished water supply with the normal fall, whereby the efficiency would be reduced just when it should be highest, if economy is at all the chief object of a turbine plant. The manner in which a high efficiency can be maintained for a diminished water supply is to subdivide the turbine into several compartments, each of which represents a complete turbine. This arrangement has been adopted by Fourneyron for his well-known outward flow turbine, and in the modern Jonval turbine. The Fourneyron turbine is provided with a cylindrical gate, which is moved vertically, whereby each compartment is opened or closed. This type has been adopted for the large power plant on the Niagara Falls, but on the European continent it is seldom used. Their efficiency is very good, but owing to the narrowness of the buckets, they are easily choked.

The Jonval turbine is a parallel flow turbine, and is, for large variations of the fall and quantity of water, subdivided into two or more concentric compartments. A subdivision in this manner renders it possible to maintain not only the power, but also the speed, under a varying fall within very wide limits.

NIAGARA POWER FOR BUFFALO.

The Niagara Falls Power Company has ordered this month from the Westinghouse Company, of Pittsburg, seven dynamos to be used exclusively for the Buffalo transmisson. These machines will have a capacity of 5,000 horse-power each. Contracts were also given to E. D. Smith & Co., of Chicago, to build a power-house extension and wheel-pit for the dynamos. The officers announce that before summer closes power will be furnished to Buffalo.

POWER TRANSMISSION TO THE CITY OF MEXICO.

Manuel Fernandez Leal, Sec. Dep. Fomento, in behalf of the executive, is reported to have entered into a contract with W. Breckman, representing Siemens & Halske, of Chicago, Ill., for the transmission of water-power to the City of Mexico from the falls in the municipality of Tenancingo. The concessionnaires agree to utilize the hydraulic force produced by the falls of San Simon Atlocomulco and Achayatla for the purpose of generating and transmitting electrical energy to Mexico, the Federal district and neighboring States.

POWER TRANSMISSION AT CARACAS, VENEZUELA

Ricardo Zuloaga, of Caracas, Venezuela, has been at Niagara Falls with Mr. W. B. Wreaks, of the Westinghouse Electric and Manufacturing Company, to view the power installation there. Mr. Buloaga is a member of the Compania Anonima La Electricidad, of Caracas. This company has a project to develop power from two falls in the El Guaire River, the power to be transmitted to Caracas and used there. One of the falls under consideration has a height of about 120 feet and is expected to give 1,000 horse-power, while the other has a fall of 225 feet and will allow of the development of 2,000 horse-power.

POWER FROM LACHINE RAPIDS.

The Lachine Rapids of the St. Lawrence are at last to be utilized. For some time work has been prosecuted on a large wing dam that runs out for more than a thousand feet into the St. Lawrence river. A fall of water is secured by means of a dam sufficient to develop at the low water season about 15,000 horse-power. This water power is to be transformed into electricity.

Upon the dam a power house will be built that will run its entire length and show an unbroken interior of 1,000 feet in length. The basement of this will be occupied by Stilwell & Bierce water-wheels. The main floor will contain the dynamos, of which there will be twelve, each of 1,000 horse-power, or 12,000 horse-power in all.

They will generate current for transmission to Montreal, for use there in lighting the city, operating the street railroads and for any and all other lighting and power purposes.

ROENTGEN RAYS.

ROENTGEN-RAY EXPERIMENTS.[1]

BY DR. OLIVER J. LODGE.

IN the course of his experiments on Röntgen rays, Professor Oliver J. Lodge used a vacuum tube, which was made with three terminals, two aluminum cups facing each other, and one platinum disc at 45 degrees half way between them, with its terminal coming out at right angles to the other two, as shown in the illustration. The following results were obtained:

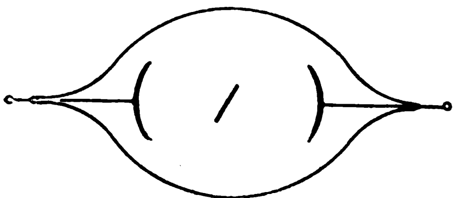
1. The cups being cathode and anode respectively, the insulated platinum disc acted as a moderately weak source, chiefly, of course, on the side facing the cathode. (The other side acts probably, only by reason of the partial transparency of platinum.)

2. The platinum being now connected to the cathode, its ray emitting power practically ceased.

3. The platinum being connected to the anode, it acted as a much more powerful source.

4. Connecting it to the anode through a Wimshurst machine in action, when the machine charged the disc positively it acted as a strong ray source; when the machine was reversed so as to charge the disc negatively it acted as only a very feeble source.

5. Shunting out the machine by short-circuiting its terminals, so as thereby to connect the disc direct to the anode, sometimes



LODGE'S X-RAY EXPERIMENTS.

improved, sometimes enfeebled, the action. With a low vacuum, such that the induction coil can readily discharge through the tube, the action is best without the Wimshurst; but with a high vacuum, such that the coil has a difficulty in discharging, the intervention of the continuous-action machine greatly improves matters.

6. If the machine is interposed between disc and cathode it does good only when it maintains a positive charge on the platinum disc.

7. Without the machine the coil usually acts best when connected so that one cup is cathode and the platinum disc sole anode, so that the charge is concentrated and not shared with any larger surface (though under extra high vacuum conditions a larger anode may become preferable).

8. The addition of the machine, between the disc and the other cup, may readily be made to strengthen the action still further.

9. It is desirable to force up and maintain the positive potential of the platinum disc in every way, e. g., by avoiding any brush discharge or other leak, and by putting the machine in series with the coil when the vacuum gets over high. The usual hasty hook mode of connection for low vacuum tubes is unsuitable for high vacuum tubes.

10. When the coil is connected to the two cups, and is in action, the insulated platinum disc in the middle becomes charged, so that a wire attached to it can emit minute sparks. The sign of this charge is, in my experience, always positive, no matter how the connection or current be reversed. Doubtless the cause of this is some brush discharge of negative electricity from other terminals; but whatever the cause, the effect is that the disc acquires the positive charge which appears necessary, and is certainly advantageous, to its action as an X-ray source, even when insulated, though, as previously said, it acts better if connected to or made the anode, or otherwise electrified strongly.

It has been asserted in France that although the X-rays are not ordinarily affected by a magnet, they will become so if passed through an electrified plate, thus acting like particles which could be first electrified and then magnetically deflected. Dr. Lodge tried a number of experiments in verification of this statement, but could find no evidence of its truth. No deflection or twisting of the X-rays could be observed, even after passing them through a highly electrified plate.

[1]Abstract from London "Electrican".

A THEORY OF X-RAYS.[1]

BY ALBERT A. MICHELSON.

THE principal facts, which any satisfactory theory of the X-rays is called upon to explain, may be summarized as follows:

(1) The production of the rays by electric impulse, at the cathode,[2] in a highly exhausted inclosure. (2) Propagation in straight lines and absence of interference, reflection, refraction and polarization. (3) The importance of density of the medium as the determining factor in the transmission of the rays. (4) The production of fluorescence and actinic effects, and the action on electrified conductors. Two theories have been proposed to account for these remarkable phenomena: (1) the theory of longitudinal waves; (2) the theory of projected particles. In reference to the first theory it may be said that unless it is proved that an oscillatory discharge is essential to the production of the X-rays, there can be no reason for supposing that these rays are of a periodic nature—that they are wave-motion, as commonly understood. The absence of interference, reflection and refraction is also a very formidable difficulty. Attempts have been made to account for the absence of these invariable accompaniments of every known form of wave-motion, but, as I think, with very indifferent success.

The most serious difficulty in the second theory is the attempt to explain the passage of the electrified particles of the residual gas (or of the electrode) through the walls of the vacuum tube. The query at once arises, if glass is permeable to those particles in virtue of their relatively great velocity, why is it not permeable (in lesser degree) to the same particles moving with smaller velocities? That it is not, is evident from the fact that vacuum tubes retain their high degree of exhaustion unimpaired for years.

In view of these difficulties, I would propose a third theory, which may be called the "ether-vortex" theory. Let it be supposed that the X-rays are vortices of an inter-molecular medium (provisionally, the ether[3]). These vortices are produced at the surface of the cathode, by the negative charge, which forces them out among the molecules of the cathode.

Let us now apply the tests above mentioned. According to this theory, an oscillatory discharge, while it may be just as effective as a series of separate impulses, is not essential to the formation of the vortices. The vortices being forced outward from the surface of the cathode by the negative charge, the effect of the positive charge at the anode would be to drive them in. Hence their appearance at the cathode alone.

One of the greatest puzzles connected with the behavior of the X-rays is the fact that while they can pass almost unimpeded through air at atmospheric pressure (let alone water, glass, wood, flesh, bone, and metals) when once outside the inclosure in which they are produced, they cannot even reach the walls of the inclosure, except there be a very high vacuum within. This problem receives a very natural solution if it be considered that, in order that ether-vortices may result from the electrical impulse, this impulse must be communicated to them; and must not be dissipated in the interchange of molecular charges which accompanies, or rather produces, the discharge at moderate or high pressures.

As exhaustion proceeds there are fewer molecules present to effect this discharge with sufficient rapidity, and as this limit is approached there will be a division of the energy of the electric impulse between the electrified molecules and the ether-vortices, and in the end all the energy of the discharge will be confined to the latter.

The reason for the non-appearance of the rays under ordinary conditions is not that the rays cannot reach the walls of the inclosure or pass through them, but that they cannot form at all. The propagation of vortices in straight lines, the absence of interference phenomena, of reflection, refraction and polarization, follow from the properties of vortices, and from the absence of anything corresponding to a wave front. The passage of an ether-vortex through a mass of matter may be compared with a passage of a smoke-ring through a wire gauze

[1] From the "American Journal of Science."

[2] Even should further experiment prove that the X-rays proper originate at the first obstruction encountered by the discharge, the fact remains that the discharge originates at the kathode.

[3] A possible objection occurs to the formation of ether-vortices in a medium which is usually considered free from viscosity; but the fact that vibrating molecules can and do communicate their motions to the surrounding ether shows that the communication of vortex motion may also be possible.

Though not a necessary part of the theory, it may be considered that the expulsion of the ether-vortices is due to an accumulation of ether in the kathode, and this would lend support to the theory that this accumulation is not merely a result of the negative charge, but that this excess of ether is what constitutes the negative charge.

screen or a series of such; and as the motion of the rings is more impeded the greater the diameter and the number of wires per unit volume, so, the greater the number and the size of the molecules—that is, the greater the density—the more effective will the medium be in dissipating the energy of the ether-vortices.

The production of fluorescence, actinic effects, and the dissipation of electric charges by light (which is an ether motion) would make it at least probable that similar (though perhaps not identical) effects would be produced by the motions of ether vortices.

Professor J. J. Thomson has measured the velocity of cathode rays and obtained a result so very far less than the velocity of light as to preclude entirely the idea of there being any connection between the two. If these results can be made to apply to the X-rays, the analogy with the properties of smoke-rings would lead us to expect such a result. The cathode rays have been shown by Lenard to have a considerable range in their properties, depending on the mode of their origin.[4] It seems likely that their velocities are to a considerable extent dependent on the potential and the suddenness of the electrical impulse; and if this were shown to be true of the X-rays, it would be to that extent a confirmation of the theory.

The foregoing evidence may be considered scarcely sufficient to entitle the proposition here advocated to the dignity of a theory, but it may at least merit consideration as a working hypothesis which may serve as a guide in future experiment.

THE SHAPE OF CROOKES TUBES AND DEGREE OF VACUUM FOR MAXIMUM PRODUCTION OF X-RAYS.[1]

EXPERIMENTS have been made by M. J. Chappuis, of Paris, to determine the actinic intensity of X-rays from Crookes tubes of different degrees of vacuum, the maximum being in the neighborhood of 1,1,000 of a millimetre for the tubes of pear shape as commonly employed. It was found that this maximum was not obtained with the same degree of vacuum in tubes whose forms were notably different.

Thus, with a cylindrical tube, such as that shown in Fig. 1, being 83 centimetres in length and having an interior diameter of 15 millimetres, and furnished at one end with a cathode plate, the following results were obtained:

P.	t.
0.025 mm.	30 sec.
0.012 "	25 "
0.010 "	14 "
0.0096 "	40 "
0.0058 "	75 "

The degree of vacuum pressure, P, was measured with a MacLeod gauge, and the time, t, which the electroscope took to discharge itself completely after being charged to a certain potential, was measured in seconds.

For the same degree of vacuum a pear-shaped tube showed

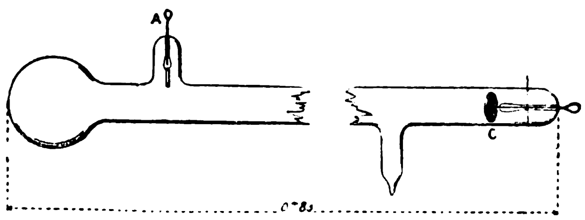


FIG. 1.

no sensible action on the electroscope. Its maximum was shown to be about 0.0011 mm., its action on the electroscope being then very intense. The discharge took place in a fraction of a second.

This particular form of tube whose length between the electrodes is 80 mm. and whose interior diameter is 15 mm., secures, for vacua relatively feeble, a fall of potential of the same order as that secured with the tubes in which the vacua are much higher.

If we adopt the hypothesis of molecular bombardment, the molecules of the residual gas would find themselves projected by the cathode with a velocity sufficient to be able to produce the emission of X-rays, and the form of the tube, in this case, would permit a larger number of molecules to participate efficiently in this action.

In attempting to utilize these results, the following tube, shown in Fig. 2, has been designed. It is made of a cylinder carrying at its right hand end a flat electrode, a circular electrode in the middle and at its left hand extremity a flat electrode, whose diameter is much larger than the principal tube. The object of this was to mask the entire diametrical section of this part of the apparatus. A swelling of 6 cm. in length formed the end of the tube behind the electrode, A. This design permits the use of A or B as the anode, C always being the cathode.

Experiments which have been made under these conditions lead to the conclusion that, to obtain the greatest production of

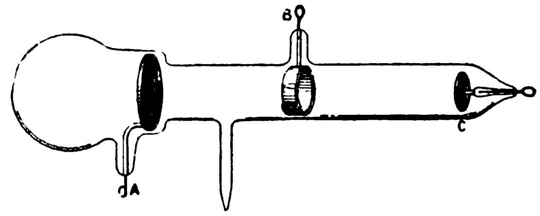

FIG. 2.

X-rays, the electrode C should constitute the cathode and the electrode A the anode. In this case no luminescence is produced in the swelling behind A.

Besides being superior for photographic work, this tube possesses other advantages over the ordinary pattern. Its life is much longer, and it permits of the reversal of the current without fear of alteration. The electrodes are all made of aluminum.

[4] The distinction between the X-rays and the cathode rays appears to be somewhat artificial, and it seems probable that the X-rays are only cathode rays sifted by the various media they have traversed.

PHOSPHORESCENCE AND X-RAYS IN THE GEISSLER AND CROOKES TUBES.

BY F. CAMPANILE AND E. STROMEI.

WE have communicated to the Acc. di Sc. fis. e mat. di Napoli (February 25th, 1896), that a spark introduced into the circuit of a Ruhmkorff coil and of a Crookes tube modifies the action of X-rays.

We call positive air spark the spark introduced between the positive pole and the tube, and negative air spark the spark introduced between the negative pole and the tube.

With rigorous experiments we have found that a positive air spark increases the effect of X-rays, and a negative air spark diminishes it. By means of various arrangements, we have also obtained the Crookes phosphorescence and the X-rays from the Geissler tube. The following arrangement (bipolar inductive) gives the best results:

On the outside of a Geissler tube are glued two pieces of tinfoil, which are connected to the poles of an induction coil. These are also in communication with a graduated sparkstand. When the coil acts, at every spark passing between the balls of the sparkstand, a discharge passes through the tube and illuminates it. Simultaneously on the wall opposite to the positive tinfoil appears the Crookes phosphorescence, which is accompanied by the X-rays. The Geissler tube in this side is transformed, monentarily, into a Crookes tube, whilst it maintains in the other regions the properties of the low vacuum tubes. In this arrangement the phosphorescence and the effect of the X-rays depend upon the length of the air-spark. There is a determined length, which produces the greatest action.

When it is unnecessary to employ Crookes tubes to obtain X-rays, the Röntgen phenomena may be produced by using low vacuum tubes without electrodes. Our arrangements are besides used to concentrate the cathodic rays, and consequently the phosphorescence and the X-rays, in a restricted side of a Crookes tube. The concentration was also obtained by employing a magnetic field.—London "Electrical Review."

STATUE OF BENJAMIN FRANKLIN UNVEILED IN CHICAGO.

A handsome bronze statue of Benjamin Franklin has been presented to the printers of Chicago by Joseph Medill, publisher of the Chicago "Tribune," and erected in Lincoln Park. About 3,000 persons were present at the presentation ceremony, the uncovering being done by Rene Bach, of Philadelphia, the great-great-grandson of Franklin.

The statue is the work of R. H. Park, the Chicago sculptor. The bronze figure is nine feet high and rests on a granite pedestal twelve feet high. It was presented by Mr. Medill in person, who made a brief address.

RAPID TRANSIT IN NEW YORK.

THE cause of rapid transit in New York City does not appear to be making perceptible progress, in spite of the urgent and growing necessity for improvement in street railway facilities. The plans of the Rapid Transit Commission, including the part underground and part viaduct road from the Battery to Harlem, and operated by electricity, was generally considered an established undertaking until last month, when the Supreme Court of this State vetoed the proposition on purely economic grounds. Although $50,000,000 was the estimated cost of this undertaking it is not improbable that before such a road could be completed this amount might be considerably exceeded, and as this sum is greater than can be readily procured from private capital for an investment of this nature. New York City's only present alternative is to secure as great extensions and improvements of existing systems as possible.

Both the Manhattan Elevated and the Metropolitan and other surface car companies express themselves through the daily press as not only willing but eager to improve the facilities of their lines, but at the same time very little is done in this direction by any of them. For the last ten years these companies have been waiting for a perfect system of motive power and ever and anon they announce that they have found it; but nothing so far has resulted from these announcements, and while these companies are waiting for something to turn up, the public are standing packed solid in trains from the Battery to Harlem on the elevated roads, or taking an hour and a half to ride up on the horse or cable cars.

The elevated roads in New York are ideal roads for the employment of electric propulsion, and if this were to be adopted by them, in addition to the west side and crosstown extensions which have been proposed, it would do considerable towards relieving the excessive pressure of travel on these roads mornings and evenings. The constant growth of the city towards the north, however, makes it improbable that any possible development of the elevated roads along their present lines will be able to fulfill the demands of travel for more than a limited time. Owning their private roadbeds, as the elevated roads do, where no danger to the public could occur from contact with electric wires, the use of a voltage of double or more that of the surface roads could be made with perfect safety, thereby securing a very large economy in the first cost of copper conductors. Moreover the subject of electric propulsion is not in an experimental state, and several similar roads in this country are successfully operated by electricity, so the officers of the Manhattan system could easily assure themselves of the better service and greater economy of electricity if they desired to investigate the subject. Their policy, however, seems to be to wait until the change is imperatively demanded.

The surface roads of New York cannot be said to be making much better progress in the improvement of their facilities than the elevated roads have done, although a number of new methods of propulsion have been tried on various lines. The cable on Broadway, after a trial of some three years, is reported to be found wanting in several respects, and it seems pretty certain that but little more extension of this system will be made. The storage battery has been given a very limited trial on other lines, but without definite results. Three or four styles of conduit roads have been installed in different sections of the city and some objections have been raised against the Lenox avenue system, which is the most extensive open-conduit system tested in this city. The verdict on the other conduit lines remains to be found.

In the meanwhile a step backward is to be taken this summer, we understand, on the Madison avenue line, which is about to try compressed air. The superiority of electric propulsion to compressed air, both as to efficiency and economy, is so thoroughly understood among engineers that it scarcely seems probable that the Metropolitan company seriously considers compressed air as a commercial possibility. The sooner both

the public and the railway companies realise that electricity is far in advance of all other methods of propulsion and intelligent effort to adopt it is made, the sooner New York will be provided with those transit facilities, in which she is now outstripped by most of her smallest suburbs.

THE ECONOMY OF WATER POWER.

THE paper read before the Institution of Electrical Engineers by Mr. A. Steiger, on the Utilization of Water Power, and which is published elsewhere in this issue, serves to draw attention to the fact that the popular impression regarding the economy of water power is in very few cases actually realized in practice, or, at least the economy is not what it would appear to be considering the energy is supplied free of charge. It is almost impossible to make any general comparison between the cost of steam power supplied from coal and water power, although this is easily done in the case of any particular plant, but it is well known to engineers that, where coal is reasonably cheap, and the water power available needs considerable development, the former power is usually the more economical. Where natural conditions, on the other hand, are favorable, water power may offer great economy, but it is not by any means safe to assume this as a general rule.

The highest allowable cost of developing water power from the dam to the point of consumption is placed by good authorities at about $140 per horse-power, where the power is to be utilized on the basis of ten hours per day. One circumstance which greatly diminishes the economy of water power in a great many cases is the necessity frequently found of adding an auxiliary steam plant to the hydraulic plant in case of the failure of the latter during a dry season, and this auxiliary plant, however little it may be used, is always the source of more or less expense to keep it in repair, and in condition to be put in service at any time.

Dr. C. E. Emery places the average annual charges against a hydraulic plant at 17 per cent. and at an original cost of $140 per horse-power, this would bring the cost of a horse-power per year up to $23.80, which is within the limit of attainment with the most economical types of steam engine and with coal at a moderate price. If the power is to be transmitted to a distance the cost of an electrical transmission plant must be included in the estimate of developing the hydraulic plant, so that while water power in some cases may prove very economical, it is not safe to assume it to be so without a very careful examination of the local conditions.

WESTERN UNION AND AMERICAN BELL.

THE formation of a company with a capital of $16,000,000 to operate telephone lines in the States of New York, Massachusetts, Rhode Island, Connecticut and New Jersey, in which officers of the American Bell and Western Union companies are represented, serves to call attention to the approaching expiration of the agreement between these two companies and their probable future relations. The agreement of 1879, which was published in full in The Electrical Engineer of August 28, 1895, expires on August 26, 1896, and with it the restrictions which have heretofore been a bar to the Bell company's entering the telegraphic field, and, on the other hand, prevented the Western Union from doing a telephone business. As a matter of fact, it is an open secret that the Bell company, through its licensee, the "Long Distance" company has for some time past done a telegraph business, consisting in the leasing of private wires to bankers and brokers. So serious had this become that an open rupture with the Western Union was barely averted and it is asserted that the latter company was only pacified by the payment of a handsome indemnity for its lost business. That a closer rapprochement between the two companies is on the tapis is probably true, but it is doubtful whether the company organized last week at Albany is intended as a step in that direction. We look upon it more in the light of a consolidation of the telephone interests centering in New York, including the Metropolitan company, and those companies which have close business connections with it through extra territorial lines. That the Western Union officers should be represented in the list of organizers is not strange, in view of the fact that that company owns 40 per cent. of the stock of the Metropolitan company, and the Bell company's representation is also easily explained on similar grounds of stock participation in the same company.

ELECTRIC METERS.

AT the recent meeting of the Western Gas Association, considerable discussion was heard on the subject of the method of charging customers for electric lighting, and as the electric light plants which are run as auxiliaries to gas plants are generally of rather small capacities, it seems still to be an open question with most of these stations whether to charge for current on a flat rate or upon a meter basis. The advocates of flat rates, who seemed to be in the majority among the gas men, based their arguments very largely upon their unsatisfactory experiences with different kinds of electric meters, and the discussion revealed the fact that these instruments are held in rather low estimation by gas men, as well as by the public generally.

The difficulties between the lighting companies and the consumers when the charge for current is made on the basis of a flat rate are numerous and, as a rule, unavoidable, yet it is difficult to convince the stockholders of a company to abandon flat rates and install meters when they regard these instruments only as an additional expense which secures no more profit to the company that is obtained under the flat rate. It is safe to say, however, that it will soon be impossible for lighting stations to supply current on any other than a meter basis, as the flat rate is not only undesirable on account of the carelessness, or even dishonesty, on the part of customers, but because of the very great difference in the quality of the lamps now on the market in regard to the watts consumed per candle-power. As between two lamps of different efficiencies, the customer who burns the one of lowest efficiency uses more current than one burning high efficiency lamps without obtaining any better light, and as there is no standard of efficiency, one customer may be paying on a flat rate for the same amount of light as another and yet using a lamp that may cost the station 50 per cent. more to feed.

Another point brought out during the discussion was the impossibility of knowing the amount of leakage on the system between the station and the customer without the use of meters; or, in other words, how much current has been sold during the month and how much remains unaccounted for.

The electric central station business was never settled upon a sound basis until the meter system was adopted, and it will eventually be found by the gas men that meters are just as much of a necessity in the electrical branch of their business as they are in the supply of gas.

THE WALKER CO. INDEPENDENT.

SINCE the recent consolidation of the interests between the General Electric Company and the Westinghouse Company rumors have been rife of attempts at, and even of consummation of, working arrangements between the former and other large electric companies. The most persistent of these refers to the absorption of the Walker Company by the combination, as noted in another column. This action, though attempted, has not been consummated, and we are definitely informed that it will not be, and that, on the contrary, the Walker Company will make a strong and active competitor to the trust. This determination on the part of the Walker Company to stand on its own bottom is only another indication of the oft-expressed belief that no one concern can, or ever will, control the electrical industry of the United States. Besides the Walker Company, there are in the field other strong concerns, both large and small, who may be depended upon to carry on active competition, and to give that stimulus to the trade without which improvement and progress would come to a standstill.

PROGRESS BY LEAPS.

A BRIEF glance at what electricity has done points to the fact that no other of the arts and sciences has had such an effect on the progress of mankind. As Mr. George Iles in the "Popular Science Monthly" for June states, the subjugation of electricity means for thought and work not merely an addition, but a multiplier. In tracing the numerous interconnections of electrical science and art with other sciences and arts an increase in progress is shown similar to a series of permutations, where each new discovery, like a factor, multiplies all that has gone before. In less than a hundred years the current first liberated from Volta's crown of cups has interwoven itself with every art and science, and comparing this rapid conquest with the slow progress of other sciences for ages past, illustrates the vast expansion of human progress with each new discovery in and adaptation of electricity.

MISCELLANEOUS.

INCREASING THE STRIKING DISTANCE AT A GIVEN E. M. F.

BY ELIHU THOMSON.

I NOTICE on pages 613, 614 and 615 of your issue of June 19 a description of a phenomenon under the head "Method of Increasing the Striking Distance at a Given E. M. F.," described by Mr. Skinner, and credited to him as a discovery by Mr. A. J. Wurts. While the experiments detailed and the extensions of them are decidedly interesting, I wish to state that the basic phenomenon or method of increasing the striking distance described is by no means new. I have known and practiced the method on occasion for at least thirty years, and I have no doubt that others have been familiar with the effect.

I originally used it when about 13 years old, to increase the spark of a Leyden jar. This I did by taking a straight limb discharging rod and slipping a test tube over the end, having first removed the ball from the limb of the discharger. The round end of the test tube was presented to the ball connected with the interior coating of the jar and the uncovered limb to the external coating, while the test tube lay on the upper limb of the discharger, said upper limb being covered for a considerable portion of its length by the test tube. In this case a discharge which would have jumped, say, one-half an inch in air was easily caused to pass over three inches, the length of the test tube.

I have frequently exhibited the phenomenon in lectures from time to time, sometimes pasting a strip of tinfoil on the interior of a glass tube from one end to the other and allowing the spark to jump to the closed end, in which case it would follow the tinfoil in passing over the exterior. A spark of a few inches would in this way be extended to make a visible stream of fire of a foot or more.

I may further remark, as showing clearly that the experiment is very old, that the old frictional plate machines used before the days of the Holtz machine and its modifications, were often provided with a silvered glass ball on the prime conductor, the silvering being done inside the ball. These balls were sometimes six or eight inches in diameter. Their purpose was to increase the capacity or extent of outside surface, so to speak, of the prime conductor, and thereby to thicken the spark obtained in discharging the same. Experimenters were accustomed to take sparks sometimes from the ball itself, in which case it was frequently noted that the spark would travel many inches over the glass surface from the neck of the ball to the point of the application of the knuckle or other discharging body, its ability to so pass over the outer glass surface being, of course, due to the inner coating of silver.

Another way of extending the spark which I used, based on the method described, was to smoke a piece of glass and then cause the discharge to pass over the surface. In this case the spark was greatly lengthened and it passed, of course, over the soot particles, at the same time making a clear space or tracing which tracing could be examined afterward with a magnifying glass and the explosive action of the spark distinctly seen.

In making these statements, I do not, of course, intend to discourage the work of experiment in this direction and the application of the results of the same to useful ends, but merely to correct what is evidently a misconception of the history of the science.

ELECTROLYTIC MANUFACTURE OF WHITE LEAD.

R. P. Williams (J. Am. Chem. Soc. 17, 835-842) describes the patent process of A. B. Brown for the electrolytic production of white lead. It consists in decomposing, by an electric current, a solution of sodium nitrate, containing about 1 lb. to the gallon, in wood cells provided with porous diaphragms; the nitric acid radical attacks the positive electrode, which is of metallic lead, and the lead nitrate solution thus formed is precipitated later by the sodium hydrate produced at the other electrode. The precipitated lead hydroxide is digested with bicarbonate of soda solution, whereby lead carbonate in a very fine state of division is obtained. The sodium nitrate is thereby regenerated. The sodium bicarbonate used is formed by passing carbon dioxide into the caustic soda solution. It is claimed that the process can be made a commercial success, the white lead being equal or superior to that made by the old "Dutch process." The plant required is small for a considerable output, and there is no loss of time, the reactions taking place rapidly. There is a great saving in labor and materials as compared with the Dutch process. The product of the electrolytic process is in a very fine state of division, and is claimed to be of a spongy character, non-crystalline, and having a greater covering power than Dutch process lead. Tests of durability show this lead to be fully equal to Dutch lead.

THE PRACTICAL TESTING OF IRON AND STEEL FOR MAGNETIC QUALITY.[1]

BY W. K. HOWE.

THE investigation of the magnetic properties of iron and steel is a very interesting pursuit and of undisputed value in the scientific world. But I have been led to the belief that a question has arisen in the minds of some as to the extent of its value in practice. Does the gain pay for the necessary expense and time for properly carrying on such tests, or is it merely an expensive luxury?

In reply to these questions, and without attempting to claim too much, I will say that testing, although not essential, undoubtedly leads to economy. It is not essential principally because it is possible to manufacture dynamo electric machinery and sell it at a profit without specific knowledge of the magnetic quality of the material used, providing you have a general knowledge of like material, such, for example, as is given by Hopkinson, Kapp and others.

Although it is possible thus to build electrical machinery, the probabilities are that it will not be well proportioned. To be sure, if a dynamo does not come out to figures, you can add to or take off wire from the fields, as the case may be, or else the speed may be increased or diminished or something else resorted to, but even after your machine has been brought, by this expensive "cut and try" method, to the proper working condition, you are not, even then, sure where the fault lies.

It may be you have used a wrong leakage coefficient, or perhaps the iron is not what you expected. The yoke may be too heavy and the magnet cores too small, or there may be more armature iron than necessary, and how are you going to find out where the trouble is? One way would be to vary the different parts one at a time and watch the effect of each change, but this would involve a great expense for machine work, etc. Another, and by far the most satisfactory way, would be to determine, as nearly as possible, the leakage coefficients beforehand and then with the previously obtained knowledge of the magnetic quality of the iron to be used, design the machine, predetermining the exact windings and proportions.

Upon testing the machine, if it does not come out to figures and if you are assured that the mechanical dimensions, winding, etc., are according to specifications, you know it is due to wrong leakage coefficients which can now be accurately determined.

Therefore, I name, as one benefit to be derived from careful testing, the power it gives one to largely predetermine the proportions of a dynamo, thus avoiding a great deal of the expensive changing which is often necessary with the "cut and try" method.

Another advantage is when there are several points of uncertainty in a dynamo, for example, the leakage coefficients, it is quite helpful in unraveling the mystery to have at least one thing definite to fall back upon. The value of testing in connection with transformer work is perhaps even greater than in building dynamos, for if a transformer is built of poor iron no change in windings or in the amount of iron will make it good. In connection with foundry work a testing instrument is of great value, especially when used in connection with chemical analysis, for it enables the foundryman to tell what mixtures and treatment will give the best results. Its advantage in purchasing metal and keeping a check on it as it is delivered is self-evident. In short, I can think of no better comparison than to liken the man with facilities for testing to one who walks with his eyes open, and the one without to the man that proceeds with them shut.

Hoping the benefits thus named are sufficient to convince any who may be sceptical that there are decided advantages to be derived from testing, let us turn to the question of the selection of samples.

No matter how eleborate the instrument or how accurately the magnetic quality may be determined, if the sample thus tested is not like the metal whose quality you are trying to determine, of what value is the best? One would suppose, on first thought, that the selection of a representative test bar would be an easy matter, but the reverse is often true. In fact, it requires no little care and experience, since there are so many conditions which affect the permeability. Some of them are as follows: The rate of cooling should be regulated, for if a test bar should be cast by itself, it would be sure to cool faster and consequently have a lower permeability than if it were allowed to cool slowly. In a case of this kind it would

[1] Read before the Chicago Electrical Association.

be well to cast the bar in close proximity to the casting itself so that the heat from the large mass will keep the sample warm. If a bar is to be cut from a casting it should be remembered that the metal at the bottom is usually the best; that in the middle the poorest, and that on the top somewhere between the bottom and center, so that the sample in this case should be taken from somewhere near the top, referring to the way it was cast.

To determine this pòint more accurately it would be well to

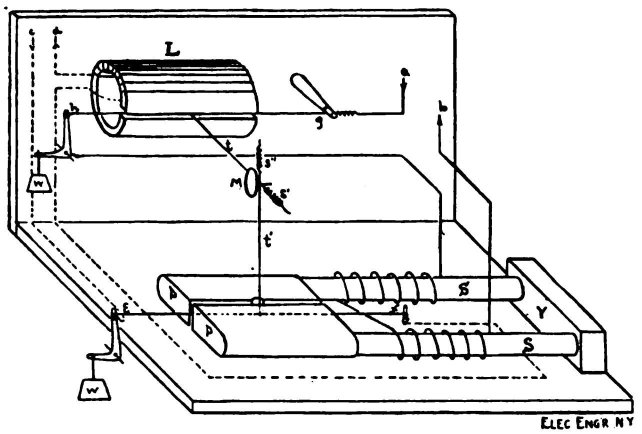

FIG. 1.—EWING'S MAGNETIC CURVE TRACER.

have, say, three bars, cut from different parts of the casting, testing each, and repeating the process a few times with different castings until sure of the locality that will give a sample of average value.

If it is desired to test a heat from a cupola it will not do to take a sample at random from any part of it, because the quality varies at different stages, and while I can give no definite information as to where the best metal is taken off, I can suggest a simple way to find out, and that is, to do the same as was suggested in connection with the large casting, namely, take off samples at different stages, being sure to cast them all in the same position and have them cool equally.

Sheet iron and sheet steel samples should be composed of a number of pieces of the proper shape taken from various parts of the lot, and not all from the same sheet, since the quality of one is not necessarily representative of all.

Of the samples sent in from outside concerns one can have but a limited knowledge of the way in which they were prepared; therefore, it is not safe to consider such tests as final, but using them as a guide a small dynamo frame should be cast to see if its permeability compares with the sample.

Since annealing has a very beneficial effect in increasing permeability, it is well, in comparing a number of samples, about the preparation of which you have no knowledge, to reduce them, as it were, to a common level by annealing them all under exactly the same conditions. If any have been previously annealed they will not improve much, but if they have not been their permeability will increase considerably.

Having selected a representative sample, the next thing that confronts the investigator is the method to be used in testing it. Since commercial tests to be of the greatest possible value must be made accurately and often, and since the bulk of the work need only be comparisons, absolute determinations being but seldom necessary, an instrument for the purpose should possess the following points:

1. It must give reliable results at all times and not depend for its action upon parts which are liable to get out of adjustment, unless such deviations can be detected and readily readjusted, or upon parts which are particularly susceptible to local magnetic influences or vibrations.

3. The form of the sample should be as simple as possible, allowing it to be quickly and cheaply made.

3. It should permit of rapid comparative tests and of calibration for absolute measurements.

4. It should be direct reading if possible, requiring no laborious corrections or calculations to get the result.

5. It should, if possible, be capable of testing both solid bars and sheet, either for hysteresis or permeability, even though other and more important qualities have to be sacrificed; for this it is better to have a special instrument for each purpose.

A number of instruments are in use at the present time, which fulfill many, if not all, of the conditions just named, but before describing those of the greatest value in practice I wish, for the sake of illustration and comparison, to mention a method which, although highly scientific and perhaps the only practical method of making original determinations, is not good for testing such as is carried on in connection with the building of dynamo electric machinery.

It is the old and well-known ballistic method, descriptions of which may be found in Ewing's work on magnetism, in Thompson's dynamo electric machinery, and a number of other works on magnetism and electricity. It depends for its operation upon the transient current induced in a secondary coil, wound around the sample, when the primary current is suddenly increased, decreased, or reversed. This induced current is proportional to the whole change of induction resulting from such change.

The instrument used to record the impulses of the transient current is called a ballistic galvanometer and is simply an ordinary galvanometer, having a weight attached to the needle to give it a large moment of inertia, compared with the directive force acting upon it. This permits practically the whole quantity of the transient current to pass before the needle has stirred, sensibly, from its position of rest. Perhaps the greatest advantage of this method is that it is possible to have the metal composing the sample in the form of a continuous ring, no doubtful corrections having to be made for foreign substances in magnetic circuit with the sample, such as air gaps or other pieces of iron, as will be noticed in subsequent instruments to be described. Another advantage arising from the ring form of sample is that the induction is uniform at all points and the magnetic circuit of positive length. The disadvantages of this method are due mainly to the galvanometer, since it is very sensitive to vibration, and it takes a long time to make a proper test.

Returning now to the instruments of a more practical character, I have illustrated in Fig. 1, the form of instrument designed by Professor J. A. Ewing and called a magnetic curve tracer.

The principle used is that whenever a wire carrying a current is placed in a megnetic field it will tend to move in a direction at right angles to the lines of force either one way or the other, depending upon the relative direction of the current and the lines of force. The force acting upon the wire is proportional to the product of the flux and current.

The instrument is constructed as follows: The specimens, S S, of which there must be two, are joined at one end by the yoke, Y, the other ends terminating in pole pieces, P P. In the instrument as actually constructed, the pole pieces have clamps that serve to hold the specimen.

Between the poles P P is a narrow slit, in which is stretched a wire, e f, that is kept under tension by a weight, W, acting through the medium of the bell crank lever, e. Above, to the left and parallel with the pole pieces, is a long C-shaped magnet, L, which also has a slit which runs parallel to the one between the poles. In this slit is stretched another wire, g h, which is kept tight in the same manner as the one between the poles, P P. Any lateral movement of these wires is comunicated, by the threads t and t' to a tiny mirror, M, which is free to deflect in any direction. The wires, g h and e f, are kept under slight tension by the springs, s' and s", respectively, and, when there are no other forces acting, these springs should bring the mirror to zero position. A tiny spot of light is thrown upon this morror and thus any movement of the wires, how-

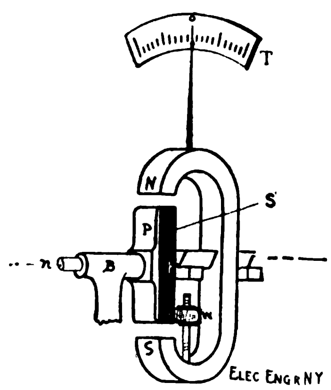

FIG. 2.—EWING'S MAGNETIC TESTER.

ever slight, is easily detected and measured by the movement of the spot of light upon a screen set up for the purpose.

In the circuit a and b is included the wire g h, the magnetizing coil around the specimens and also a rheostat (not shown) for varying the current. The circuit c d (dotted for sake of clearness) includes the wire e f and the C-shaped electro magnet, L. The current in this circuit is kept at some constant value.

Since the current flowing in g h is the same as that producing

the magnetomotive force, H, and since this wire is in a magnetic field of constant strength, its movement will be proportional to H, and since the flux across the slit between the pole pieces is directly proportional to the density, B, in the specimens, the movement of the wire e f carrying a constant current, will be proportional to B.

If the wire e f is cut out of service for a moment the wire g h will cause the spot of light to trace a horizontal straight line

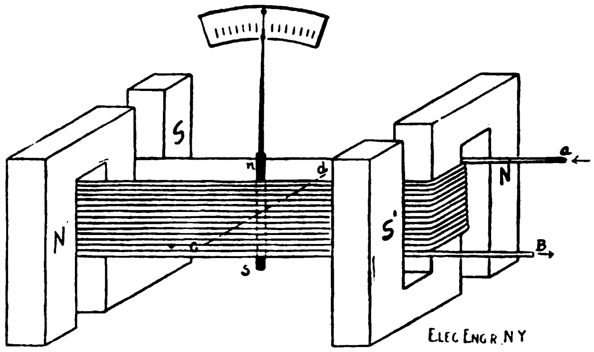

Fig. 3.—Eickemeyer's Differential Magnetometer.

on the screen which we will call the H axis. Likewise if the wire g h is made inoperative for a short time e f will trace a verticle straight line which will be the B axis.

The resultant deflection of the mirror, due to the action of the wires, will place the spot of light in such a position that its horizontal distance from the B axis will represent H, and its vertical distance from the H axis will represent B, so that by carrying the magnetizing force from zero up to full value, the curve of permeability will be traced and by carrying it through a complete cycle the hysteresis loop will result.

With this instrument samples may be rapidly compared, and if the permeability of one has been previously determined, the absolute value of any of them can be found by proportion. Slight variations in the adjustment of the instrument from time to time will make no difference, since they will affect the curves of the standard sample in the same proportion as those of the samples under test. One of the advantages peculiar to this form of instrument is that the moment of inertia of the moving parts is so light that rapid cyclic variations of the magnetizing force may be carried through and the corresponding hysteresis cycle observed since the spot of light in moving so rapidly traces a continuous curve. In calculating the mag-

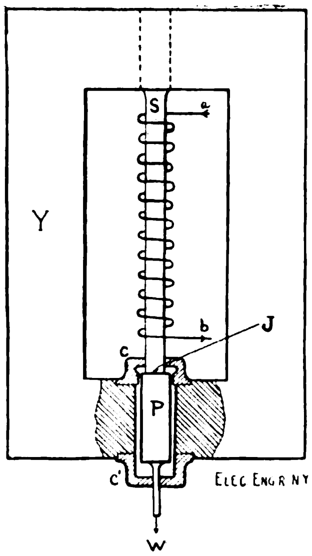

Fig. 4.

netomotive force required to drive the flux through the samples alone a correction must be made, for the force used up in driving it through the yoke, pole pieces and air gap. In regular testing the spot of light is made to travel over a sheet of paper put up in place of the screen and its successive positions marked with a lead pencil.

In Fig. 2 is shown another instrument designed by Ewing for measuring hysteresis. It consists of a permanent magnet, N S, pivoted on a knife edge. Between its poles is rotated the specimen S'. The work lost in reversing the magnetism in the specimen rotates the magnet sidewise against the force of gravity. Since the deflection is proportional to the work thus lost it affords a ready means for comparing the hysteresis of different samples. The deflection is indicated by the pointer on top of the magnet which plays over a scale, T, and the instrument is made more or less sensitive by moving the weight, W, up or down.

The samples are very easy to prepare, consisting of a few simple rectangular strips 3 inches long by ⅝ inch wide, which are filed to the exact length in a gauge furnished with the instrument. Since sheet metal comes in various thicknesses, it is best to use a definite weight of material for the sample.

The air gaps between the sample and magnet are quite long and consequently offer an enormously greater reluctance to the passage of the lines of force than the sample, so that if different samples should offer different reluctances, these differnces would be such a small percentage of the total reluctance that the indication will be practically tne same for all samples, a condition that is of prime importance in making comparisons with this instrument. Of course the induction produced by a permanent magnet is relatively small, but this makes very little difference, since it is a pretty well established fact that the hysteresis varies in all samples in about the same proportion. Standard samples of known quality are sent with each instrument, so that one can tell by comparison tne actual loss in his sample.

The same is rotated oy hand through the medium of a large

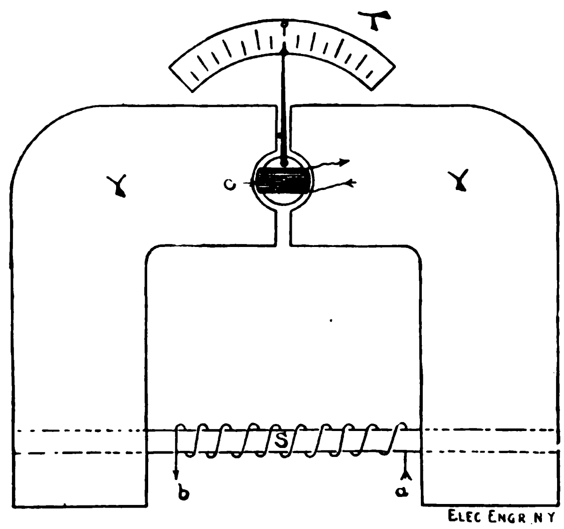

Fig. 5.

friction wheel, which bears against a small one on the shaft n that carries the sample. The speed of rotation is a matter of no particular importance, provided it is not so slow that the readings are unsteady. This is true because the work required to carry the magnetism through a complete cycle is the same, as far as hysteresis is concerned, no matter how rapidly it is done, and although it requires more power to turn the sample rapidly, its drag on the magnet is no greater unless it be that the fanning action of the sample and the eddy currents have an effect. If they do it will be shown by a gradual increase of the readings as the speed is increased. The preparation of samples is so inexpensive and the operation so rapid and simple that it makes it an admirable instrument for practical work.

In Fig. 3 is shown the Eickemeyer differential magnetometer. It is a zero instrument, the principle involved being that of the differential galvanometer, in which the same current is made to flow in opposite directions through equal coils ,which are in series and situated symmetrically with respect to a polarized needle. The coils having equal and opposite effects upon the needle, it remains in zero position unless one of the coils is shunted by a resistance. In this event the other must be equally shunted to bring the needle to zero again.

This method of comparing two resistances is employed in the differential magnetometer, as follows: Two heavy S-shaped pieces of Norway iron are placed parallel with each other, as shown in the figure, so that their front and back faces are in the same plane, respectively.

Around the central portions of these pieces is wound a magnetizing coil, A B, which magnetizes the soft iron needle, N S, and causes it to point to zero on the scale. This magnetizing coil also causes lines of force to flow from N to S on the

back and from N to S on the front of the instrument, but they have no effect on the needle since the flux is equal and opposite. However, if the air path, N S, is shunted by laying a piece of iron against the back of the pole pieces some of the lines which previously passed through the air will now flow through the iron and their different effect removed from the needle and it will deflect to the right, due to the excess of free lines flowing from N to S.

In order to restore the needle to zero a piece of iron of equal reluctance must be laid against the front pole pieces. Now suppose that the piece of iron laid against the back of the pole pieces was a sample of unknown value and that the piece on the front is iron of known permeability, it is quite evident that the permeability can be found by the ratio between the cross sections of the two. If the sections are equal the permeability is the same. If the standard bar is of greater section the same is better, and vice versa.

The standard bar, instead of being solid, is divided into a number of strips for facility in altering its section. If no combination of these strips can be found that will give a zero reading, the current in the magnetizing coil can be changed a little to make it come right. Closely surrounding the needle is a small coil, not shown, which, when excited in an opposite direction to that of the magnetizing coil, reduces its directive force, making the instrument more or less sensitive.

In Fig. 4 is shown an instrument originally designed by S. P. Thompson and recently modified by Kapp. The underlying principle is the law of attraction, namely, that the force required to pull apart two pieces of iron which are magnetized varies, as the square of the induction and the area of contact.

The construction of the instrument is as follows: The specimen, S, is firmly held in the top part of a massive soft iron yoke, Y; the lower end terminating at J is faced off truly and is held central by the brass collar, C. Below the specimen is a small soft iron plunger, P, which is guided at its upper and lower ends. Its upper end is faced true and is held against the lower end of the specimen by magnetic attraction. At its lower end is fastened a scale pan, W, for receiving weights.

Its operation is as follows: A certain measured current is sent through the magnetizing coil, a b, and then weights are added until the plunger is pulled off. From the area of contact at J and the total weight of plunger, scale pan and weights, the induction is calculated by the following simple formula:

Let $B =$ the induction per square centimetre;
Let $A =$ the cross-section of the specimen in square centimetres;
Let $W =$ the weight in pounds.

$$\text{Then } B = 3{,}345\sqrt{\frac{W}{A}}.$$

To find H, let M be the total ampere turns in the coil, a b. Let N be the ampere turns required to drive the flux through the plunger, air gap and yokes, found by calculation from the known dimensions of the instrument or by experiment, in a way to be explained later, and let L be the length of the sample in centimeters from the yoke down to the contact J.

$$\text{Then } H = \frac{M-N}{L} \times \frac{10}{4\pi}.$$

These calculations may be greatly simplified in practice by plotting a curve of B and the corresponding pounds pull, using some standard section for the sample. From this curve the value of B can be taken directly when the tearing off weight is known. Furthermore, a curve may be plotted with W as ordinates and N as abscissae from which the number of ampere turns for the yoke, air gap and plunger corresponding to any weight may be taken directly and thus H found more easily. If it is desired to obtain the magnetizing force for the frame more accurately than is possible by calculation, a sample of known permeability can be tested and its curve plotted to the same scale and on the same sheet with the known B H curve of the sample. The horizontal distance between the two curves at any value of B will give a value from which the magnetizing force expended in the frame may be absolutely determined.

In Fig. 5 is shown an instrument for making either permeability or hysteresis tests, suggested by Mr. L. T. Robinson. It is constructed as follows: The specimen S is held, by suitable clamps in the two massive pole pieces, Y Y, which embrace a cylindrical armature of soft iron, around which is wound a fine wire coil, C, in a longitudinal direction. The magnetic flux across the gap between the pole pieces is proportional to the induction in the sample produced by the magnetizing coil, a b. The rotative force brought to bear upon the cylindrical armature, when there is a constant current flowing in the coil, C, is proportional to B. This force acts against a coiled spring so that for any given induction the pointer will stand at a definite place on the scale. The instrument may be calibrated by using a sample bar of known permeability, as in some of the other instruments which I have described. One of the advantages of this form of instrument, as in Ewing's curve tracer, is that B may be read directly. H, however, has to be calculated by subtracting the ampere turns for the frame and air gap from the total, as described in connection with Fig. 4.

Several other ingenious and practical methods for testing iron and steel have appeared in the electrical papers from time to time, among which is one described by Mr. Frank Holden, and used at the works of the General Electric Company. It is used for measuring hysteresis and eddy current losses and consists of a revolving electro magnet, between the poles of which is pivoted the specimen to be tested, consisting of a number of rings built up similar to the core of a ring armature. The work lost in reversing the magnetism in the specimen tends to rotate the armature against the action of a coiled spring and a pointer, which moves over a graduated scale, registers the amount of work lost. A stationary coil held between the armature and pole pieces, but not touching either, gives a voltage proportional to the flux passing through the armature. This instrument is much like Ewing's magnetic tester, Fig. 2, except that the induction can be varied and measured and also the magnets revolved instead of the specimen. It is of value not only in testing for hysteresis, but enables one to decide upon the proper thickness and insulation of the sheets used in armatures and transformers.

Having mentioned, in connection with the instruments just described, the need of a standard sample of known permeability, I suggest the following way of obtaining one: Have two samples prepared, of exactly the same material, one in the form of a ring and the other to fit your instrument. A test of the ring by the ballistic method will give the B-H curves of both samples. Assuming that there will be those who desire further information regarding the instruments, I have described, and wishing to acknowledge my indebtedness to certain articles which have appeared from time to time, I take pleasure in referring to them.

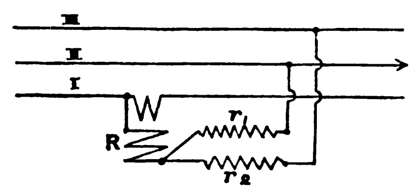
Professor Ewing's magnetic curve tracer (Fig. 1) is described by himself in The Electrical Engineer, June 21, 1893, and also in a current number of the London "Electrician." The magnetic tester (Fig. 2) is described in the London "Electrician" and "Electrical Engineer" in April and May, 1895.

The differential magnetometer (Fig. 3) is well described by Mr. Steinmetz in The Electrical Engineer, March 25, 1891. The instrument shown in Fig. 4, and also a method for measuring hysteresis, is described in the London "Electrical Engineer," February 23, and March 2, 1894, by Kapp. Mr. L. T. Robinson describes the form shown in Fig. 5 in "Electrical World," February 24, 1894. Mr. Frank Holden gives a description of his instrument for measuring hysteresis, etc., in the "Electrical World," June 15, 1895. Other articles of interest on the subject of iron testing will be found in The Electrical Engineer, April 9, 1890, and July 13, 1892, and in the "Electrical World," June 8, 1895. In the fourth edition of Thompson's Dynamo Electric Machinery and in Ewing's book on magnetism will be found descriptions of other methods which I have not mentioned.

MEASUREMENT OF THE POWER OF TRIPHASE CURRENTS.

DR. BEHN-ESCHENBURG describes a very simple method of measuring the power transmitted by the three conductors of a triphased system, in the "Electrotechnische Zeitschrift."

It is generally known that when we are at some distance from the neutral point, or when this point is not accessible or does not exist (triangular winding), and when the current is not



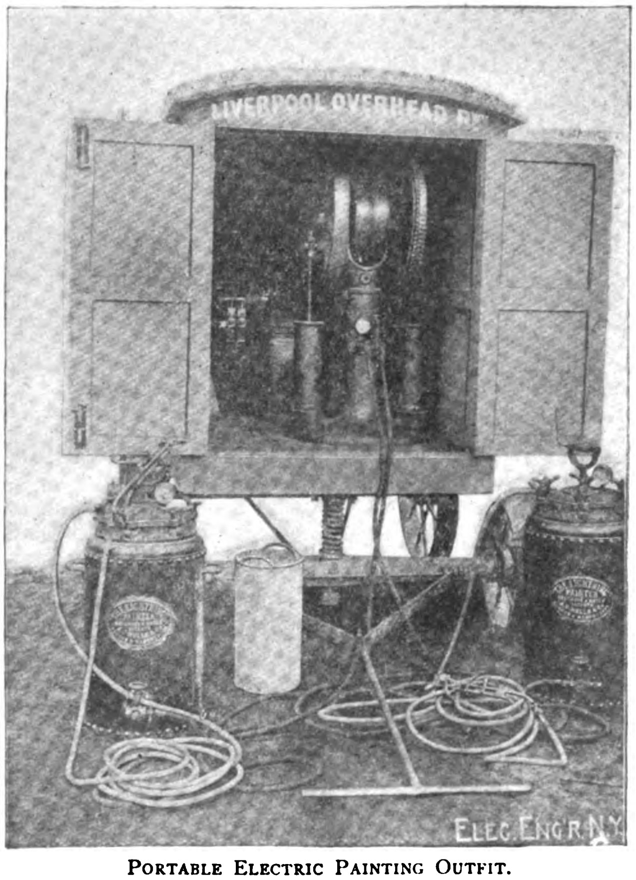
MEASURING POWER OF TRIPHASE CURRENTS.

equal in the three branches, the measurement of the power by the aid of an ordinary wattmeter may present some difficulties especially if there is no compensating wire. There is, however, a means of arriving quickly at the result by using an ordinary Siemens or Ganz wattmeter, or even, which is still more practical, a Siemens electro-dynamometer branched like a wattmeter. It is, however, necessary that the resistance, R,

of the coil of the apparatus in parallel should be small in comparison with the non-inductive one which is to be placed in series with it. We use two equal auxiliary resistances, r_1 and r_2, placed in parallel on the movable coil and connected to two different principal conductors, the other extremity of the coil being branched on the third principal conductor, as shown in the accompanying figure. The current circulating in this third conductor passes through the fixed coil of the wattmeter. The effects of this combination are as follows: The current passing through the movable coil is equal to the sum of the currents passing through the resistances, r_1 and r_2, which are in proportion and correspond in phase to the difference of potential between their respective conductors. The indication of the wattmeter, therefore, gives directly the measurement of the total power of the triphased currents, although the charge of the branches is unequal. In this method, we substitute the total effect for the separate effects of the two coils in parallel, which might be determined successively by two different measurements according to the old method, by using first one of the branches and then the other.

PORTABLE ELECTRIC PAINTING PLANT FOR THE LIVERPOOL OVERHEAD RAILWAY.

ONE of the minor but by no means small advantages of an electric system of traction is the existence along the line of power which can be used for driving portable repairing and painting machinery. In any trolley system, or where there is a continuous supply of power by surface conductor rails, as in the City and South London Railway, and the Liverpool Overhead Railway, or again in conduit systems, it is not at all difficult to run an electrically-driven repairing tool by means of power derived by tapping the main power conductor at any convenient point. Thus repairs may be performed more quickly



PORTABLE ELECTRIC PAINTING OUTFIT.

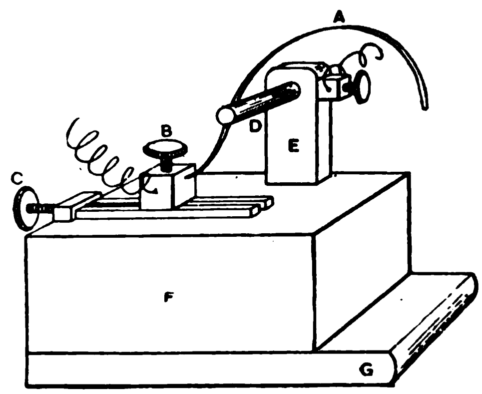
and cheaply than by hand, and heavier repairs than could be done without the aid of motor power can be performed in situ.

The latest example of this use of electric power is to be found in a portable painting plant, which has been built by Messrs. A. C. Wells & Co., of London and Manchester, for the Liverpool Overhead Railway. The accompanying illustration has been prepared from a photograph of this plant. Within the car which has been specially built for this painting machine is an electric motor, coupled to the force pump of a Wallwork & Wells spraying painter, together with the paint reservoirs, hose and auxiliary details. This car can be run on the tramway which lies immediately beneath the overhead track of the electric railway, and by means of flexible cables power can be obtained from the surface conductor on the electric line above. By this means the whole of the entensive girder work on which the electric railway is carried can be covered by the paint spray. Hitherto some forty hands have been required for painting these girders, and there is little doubt that great economy of time and labor will be effected by the new arrangement. The spraying method, we should mention, is not only used for painting extensive surfaces with a uniform color, but also by the aid of stencil plates, it is adopted for painting letters and ornamental work.—London "Electrician."

AN ELECTRICAL TREVELYAN ROCKER.[1]

BY T. A. VAUGHTON.

THE following account of what appears to be a new electrical phenomenon which I have been investigating will probably be of interest to the readers of "The Electrician." In making these investigations, I have used an apparatus, of which the accompanying illustration shows the general form, which I have manufactured in the following manner: A piece of watch-spring, A, curved into the shape shown, is fixed into the terminal, B. This terminal moves along a slide and carries the spring with it, and by means of the screw, C, the pressure of the spring against the metallic rod, D, is regulated. This rod is supported by a wooden support, E, and the whole is fixed onto the top of a wooden sounding box, F, which has a projecting piece, G, by means of which it may be clamped down to the bench when in use. On regulating the pressure with which the spring presses against the rod, and the position on the spring of the point of contact, a point will be found on which the spring, when pulled on one



AN ELECTRICAL TREVELYAN ROCKER.

side and released suddenly, will vibrate freely in a transverse direction. If, while the spring is thus vibrating, an electric current of a definite strength be passed through the bar and down the spring, the vibrations will be maintained and a musical note will be given out, the pitch of which depends on the length of the free end of the spring. The temperature of the spring and rod gradually rises until a point is reached at which the vibrations cease.

If the apparatus is immersed in water or alcohol just deep enough to cover the point of contact between the spring and rod, the vibrations take place as before, but the sound emitted is weaker. By placing a small split bullet in various positions on the free end of the spring the rate of vibration may be varied and the amplitude increased, and by fixing a small concave mirror on to the spring and reflecting a spot of light from it onto a screen the vibrations may be magnified and observed.

The steel spring may be replaced by one of platinum or German silver, but in these cases the vibrations are more feeble. Rods of almost any hard metal may be used, but steel gives the best results, and is followed by iron, German silver, platinum, brass, gas carbon, aluminum and nine-carat gold, in the order named. I have not been able to obtain any sustained vibration with rods of copper, silver, tin and lead, although even with these metals the dying away of the vibration appears to be considerably retarded by the passing of the current. No visible sparking takes place, and there seems to be no interruption of the current.

These phenomena appear to be the effects of the heat gen-

[1] London "Electrician."

erated at the point of contact, although the fact of their taking place under water would at first sight seem to negative this assumption. The apparatus appears to be a sort of electrical Trevelyan rocker.

I have not been able to obtain any results with springs of good conducting metals, such as gold, silver and copper, with any current I have used.

ELECTRIC HEATING.[1]

BY EDWARD PUCHTA.

THE possibility of heating air by electricity for warming purposes has always existed, but its limited application is for the most part due to the cost of generating the electricity, as compared to some of the other more direct methods of heating. I say more direct, because in the case of an ordinary low pressure steam heating system, or a hot water heating system, we have what may possibly be termed one conversion of energy, viz., the generating of heat by the burning of fuel, which is then given up directly to the water in either case, and then distributed throughout the system in the form of low pressure steam or hot water; whereas in the case of an electric heating apparatus we have this conversion or change to high pressure steam usually, then by means of steam engine it is converted into mechanical energy, and lastly, by dynamo into electrical energy, whence it is distributed and again converted at any desired place into heat energy, by individual machines, as we may rightly term electric heaters. However, in our modern electrical plants electricity is generated on such a large scale, i. e., in such quantities, as to minimize cost of production, and this makes it possible for electricity to compete very favorably in some cases with steam or hot water, especially when its advantages over the other systems are properly presented and considered.

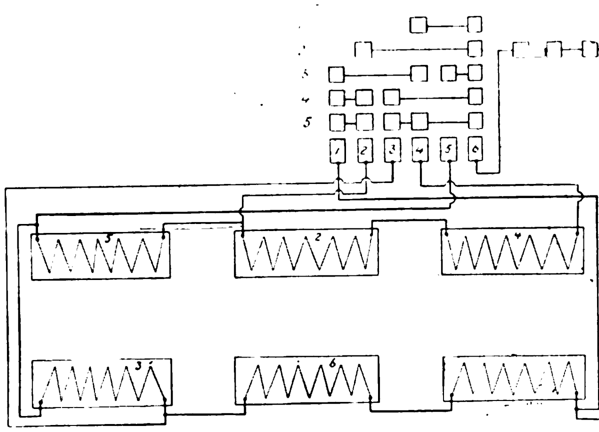


DIAGRAM OF CONNECTIONS OF ELECTRIC CAR HEATER.

Electric heaters designed for the artificial warming of air, are made in a great variety of forms, but consist essentially of a metallic conducting wire, generally of galvanized iron, or German silver, loosely coiled, so as to give an extended radiating surface, and supported in the air on insulators. This makes the heater what may be termed an air heater, the resisting conductor being so arranged as to permit the air to strike it directly and thus carry away the heat by convection currents. Such a heater serves its purposes best when it rapidly imparts its heat to the surrounding air and never itself acquires a dangerously high temperature. This latter fact is taken care of automatically in case iron wire is used in the heater, on account of its variable resistance for varying temperatures.

For example, a coil of iron wire, having a resistance at 0° C. of 100 ohms, has its resistance doubled when the temperature is raised to 180° C., and its resistance is increased to 500 ohms when its temperature is 525° C. The change of resistance in German silver, on the other hand, is but a mere fraction of this, for the same changes of temperature.

An article by Mr. J. F. McElroy cites the following case: Two electric heaters, one of German silver, the other of iron wire, both having the same resistance at 0°C. and both being covered with a non-conducting hood to prevent the escape of heat, will, as the temperature rises, act very differently.

For example, if the temperature rises to 300° C., only two-fifths as much current would pass through the iron wire heater as passes through the German silver one. This throttling action of the iron wire increases even more rapidly than the temperature, so that at 600° C., about one-fifth as much current passes through the iron wire heater as through the German silver. In each case the reduction of current means also a reduction in the amount of heat generated, the latter being directly proportional to current flow. A commercial heater, therefore, provided with an iron resisting conductor has this peculiarity, that, if for any reason the escape of heat from itself is prevented, either purposely or accidentally, the action of the consequent rise of temperature upon the heater itself is to throttle the amount of current passing through it, current flow being inversely proportional to resistance offered it, and hence the amount of heat generated, so as to prevent in the end a dangerously high temperature.

Heaters used on electric railroad circuits take their current from the mains at a constant pressure of generally 500 volts. In order to vary the current passing through the four or six heaters employed in each car a revolving or cylinder switch is used, by means of which the separate heater coils can be connected in series, or in parallel series, or some of them cut out altogether, thus permitting of a regulation of temperature and a supply of heat to meet any requirements.

The connections from the switch to the trolley wire and to the ground through the various heaters, for a car heated by six heaters, is shown in Fig. 1.

In position No. 1 all the coils or heaters are connected in series, so that the current passes through each in succession. This is the position of greatest resistance, and consequently of least current flow for a given pressure or voltage, and, therefore, of minimum rate of developing heat.

In position No. 2, two heaters are entirely cut out, which consequently diminishes resistance by one-third of itself, assuming that all heaters have the same resistance, and neglecting resistance of remaining conductors necessary for connections.

In the third position the six heaters are connected in two series of three each, giving a current strength in each set of three equal to twice the original current in the first position, making a total flow of current now of four times the original amount, and increasing heat producing power to four times the original.

The fourth position makes two series of two each, and entirely cuts out two remaining heaters, and the fifth position makes three series of two each.

In a heating coil it is intended that all the energy of the current passing through it must appear as heat, which is given directly to surrounding air by the cooling of the coils. Hence if we neglect the small portion of heat dissipated by conduction, an electric heater may be termed a nearly perfect machine for converting electric energy into heat energy.

The temperature produced in any given set of heaters in the case of car heating will depend largely upon the temperature of the external air, the speed of the car, direction and intensity of wind, construction of cars and care exercised by conductors in promptly closing doors when passengers enter and leave the cars. The number of people in a car also affects quite materially the amount of heat required. Experiments have been made in this direction, and it has been found that each person gives out about 190 B. T. U. of heat per hour, so that the heat given out by fifty persons will almost maintain the same temperature in the car that is required under average conditions.

We can readily determine the actual amount of heat produced in electric heaters when we know the current consumption, for if we multiply the number of amperes passing through the heater by the difference in potential at terminals of heater, and divide this number of watts by 1,050, we get very nearly the number of B. T. U. of heat generated per second in the heater.

The Metropolitan West Side Railroad Company, of Chicago, use electric heaters for warming their cars. There are twelve heaters for each car, connected up in three sets or series of four heaters each, with an independent switch for each set. The cars have an average capacity of 2,200 cubic feet, and about 200 square feet of glass surface. Each of the two sets of large heaters takes about 2,600 watts, and the set of small heaters about 1,800 watts, making a total of 7,000 watts per car when all circuits are on, and it is said that this will keep the car temperature between 56° and 60° F. when the outside temperature is from 0° F. to 10° F. below zero.

Some statistics show the cost of heating cars by electricity to be $2 per horse-power, per month, this being made possible by the fact that the generating plants have been erected with good boilers, efficient engines and large unit generators.

Outside of car heating, these heaters have been used in the heating of office buildings—that of the Cataract Construction Company at Niagara Falls being an example.

In England and France some large installations have also been made, that of the Vaudeville Theatre of London being probably the largest one. In designing the heating system for

[1] Read before the Chicago Electrical Association, May 15, 1896.—Abstract.

this latter building the engineers had to compete with a hot water heating system. It is now found that in ordinary cold weather only two or three hours of heating is necessary, whereas, in the case of a hot water system, for the same purpose, it would require two or three hours' time to heat up the water of the system alone.

In conclusion I might cite a few cases in which electric heat is used to advantage in other directions. Enough has been accomplished to show that electric cooking apparatus is practicable and economical in running cost, and very simple to operate.

An equipment in a brush factory for heating pitch to a temperature of 300° to be used to fasten bristles in the brushes has given entire satisfaction. Hot plates and glue pots are also heated by electricity, and an installation in a linen factory of 125 nine-lb. sad-irons heated to a surface temperature of 750° is another success.

Finally, to quote from an article by Mr. M. S. Hadaway, Jr., "It is not too much to claim that electric heating will materially influence the work of heating and ventilating engineers. Now that electric lighting installations are handled by heating and ventilating engineers, it is a short step to render the entire heating system homogeneous, looking to one source —the boiler—for all the energy needed for heating, ventilating and lighting."

STREET LIGHTING CONVENTION AT NEW HAVEN.

At the street lighting convention, held in New Haven, June 18 and 19, a number of papers were read of an electrical nature, among them the following: "Merit of the Insulated Pole," by E. E. Davis, Boston; "Electric Street Lighting," by M. J. Francisco. Much of the time of the convention was occupied by papers and discussions on the question of municipal ownership, among the latter being papers on "Municipal Ownership of Gas and Electric Plants;" affirmative, T. B. Persse, Hartford; negative, Allen R. Foote.

The following officers were elected for the ensuing year: President, B. L. Lambert, New Haven; vice-presidents, H. A. Knight, Worcester, Mass.; Oliver E. Green, Providence, R. I.; C. E. Thompson, Binghamton, N. Y.; secretary, Henry Hopkins, New Haven; treasurer, Joseph Births, Hartford; Executive Committee, D. Huntley, Jr., Allegheny, Pa.; Thomas E. Diveney, Fall River, Mass.; J. F. Fagan, Portland, Me.

The exhibits were shown in rooms 10 and 11, City Hall, and the convention was held in the aldermen's chamber. The companies to show exhibits were the Boston Electric Insulated Pole Company, Boston; E. P. Gleason Manufacturing Company, New York; S. W. Scranton, New Haven; H. Hungerford, Hartford, and a number of gas exhibits. Some street signs were also shown by S. W. Scranton.

EDUCATIONAL.

CORNELL UNIVERSITY ELECTRICAL COURSE.

We are in receipt of a catalogue announcing the courses of instruction in physics in the Cornell University. The equipment of the apparatus rooms of this department is a very large one, being valued at about $50,000, and contains a very complete outfit of electrical apparatus and instruments of precision.

Work in applied electricity is carried on in a separate building arranged for that purpose. On the lower floor of this building is the dynamo laboratory of the department, a room 35 x 100 feet. It contains two main lines of shafting extending the entire length of the room and each driven by an electric motor of 50 horse-power. More than forty dynamos and motors of various types and sizes are in constant use for experimental purposes and there are available also large batteries of accumulator cells (about 150 cells). Alternating currents of various potentials are obtained by means of specially constructed transformers, directly from the lines of the city company. The upper floor of this building contains laboratories for electric light photometry and for various studies in electro-technics.

PERSONAL.

MR. E. J. WESSELS, general manager of the Standard Air-Brake Company, leaves for Europe on June 30, to look after the interests of his company abroad. We dare say he will return with a good batch of new, as well as repeat, orders as the result of his trip.

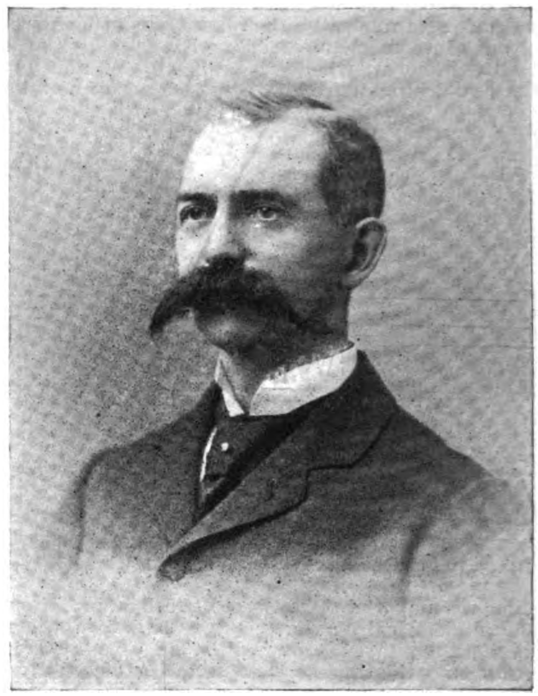
MR. ETHAN ALLEN DOTY, president of the Brooklyn Edison Company, is off on a pleasure tour through Europe, and is expected to return about September 1. Besides being president of this company, Mr. Doty is also a member of the well-known paper manufacturing firm of Doty & Scrimgeour. During Mr. Doty's absence Mr. Edward Packard, the vice-president of the Brooklyn Edison Company, is acting in his stead.

OBITUARY.

HARRISON J. SMITH.

It was but a few weeks ago that we gave a brief account of the valuable labors of the late Harrison J. Smith in connection with the recent Electrical Exposition in New York, and last week it was our sad duty to announce his untimely end in the prime of life.

Mr. Smith was born in Hector, Schuyler County, New York, in 1854, and received a common school education in Elmira. During his early life he worked as a carpenter in the Pullman car shops, and subsequently as a machinist on engine construction. He also fired a locomotive for a short time.



HARRISON J. SMITH.

In 1881, house carpenters were advertised for by the Edison Electric Illuminating Company of New York in connection with the construction of the historic Edison station in Pearl street, and Mr. Smith, with a few others, was engaged. He continued with the company as carpenter and machinist until 1883, and, after an interim of a month, entered the meter department and subsequently became its head. He left the company for about a year to engage in the wiring business, but returned in October 1885, as electrician of the Pearl street station under Mr. Chinnock, and subsequently became superintendent of the first district. Later on he was appointed general operating superintendent of the company, which position he occupied at the time of his death. The funeral services, according to the Masonic rites, were held at Scottish Rite Hall on June 18, and were attended by a host of the sorrowing friends of the departed, to whom he had endeared himself by his ever-cheerful and kindly disposition.

MICHAEL J. SULLIVAN.

We regret to announce the death, at Washington, D. C., on June 12, by appendicitis, of Mr. M. J. Sullivan. As the former representative of "The Electrical World" in New York and later in Chicago, Mr. Sullivan enjoyed a wide circle of acquaintanceship among the electrical fraternity, who will regret his untimely taking off. Mr. Sullivan leaves a widow, to whom we extend our sincere sympathy.

EXHIBITION NOTES—VII.

EXHIBIT OF THE BABCOCK & WILCOX COMPANY.

THE exhibit of the Babcock & Wilcox Company, makers of forged steel sectional high pressure boilers, was situated on the ground floor and covered a space of 500 square feet. They exhibited the various parts of their sectional water tube boilers, arranged in such a manner that the visitor was afforded every opportunity for the most critical examination of each individual part. The lighting of the exhibit was a feature that drew forth pleasing comment from many visitors.

A 36 inch steam and water drum was shown arranged on rolls, which enabled the attendant to so revolve the drum as to bring into view every portion of its construction in order that the visitor might more minutely examine the design and workmanship. The cylindrical portion of the drum is made of three sheets of open hearth steel. The longitudinal seams are butt-strapped inside and out. All holes are punched five sixteenths of an inch smaller than the diameter of the rivets to be used, through steel templates, and drilled out the full size after the sheets are rolled and assembled with the butt-straps in position. After drilling, the straps are removed, all burrs cleaned off and the plates re-assembled, metal to metal, with parallel turned bolts fitting the holes before riveting. Each course is then built independently to template.

The various courses and their heads are assembled by a hydraulic forging press at a pressure of 12 tons. All rivets are driven with a 60 ton pressure and held until cold. The drum-heads are fitted with manholes. These are forged at a single heat with the extra manhole rings and stiffening plate in position and have flat raised seats for stand pipe and feed connections. The edges of the head and manhole faces are

EXHIBIT OF THE BABCOCK & WILCOX CO.

machined off true. The manhole fittings are of forged steel. The plate is machined first and turned to a true oval to fit the head. The steam flanges are of forged steel recessed to make a male and female joint, fitted with stud bolts, tapered threads and inside keeper nuts. This standard steam and water drum is tested in the shops and again when erected on the purchaser's premises to 300 pounds hydrostatic pressure.

The cross-boxes into which are expanded the water circulating uptakes are forged from a single sheet of open hearth steel without seams or rivets.

The three sections shown, and used as a fence around the exhibit, were built up of 4 inch tubes expanded into forged steel headers. These tubes are made of the best knobbled and hammered charcoal iron blooms of standard weight and of such quality that a 1,500 pound hammer dropped five feet onto a tube shall crush the tube without showing cracks or flaws. These sections are subjected to a hydrostatic pressure of 400 pounds after assembling.

The header shown standing upon end is forged from a single sheet of open hearth steel, serpentine in form, disposing the tubes in a staggered position when assembled in the furnace. The method of expanding the tubes was shown, as also the cap clamps and handhole fittings.

The handholes are of sufficient size to permit the cleaning, removal and renewal of a tube, the handholes being placed opposite the tube ends. They have a raised seat milled off to a true surface and covered on the outside with a forged steel cap (also milled to a true surface) and held in position by a forged steel safety clamp, closing the handhole opening on the inside and secured by a bullhead bolt to secure correct alignment, and a forged cap nut. This method of closing handholes is a perfect one mechanically, insuring a tight joint, metal to metal, without packing of any kind.

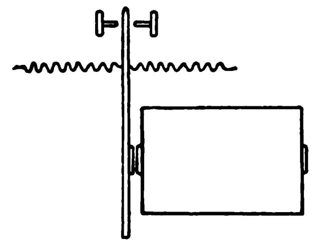
They also showed a line of high pressure brass steam boiler fittings designed for any pressure demanded. These fittings are the design of the company and are now in use on boilers working at 350 pounds pressure. Photographs of many of the large plants installed by the company were exhibited, and also photographs of their chain-grate automatic stoker. There was also shown a model of the company's standard high pressure sectional boiler. The historical side was represented by the original model of the inclined water tube boiler constructed by Mr. Stephen Wilcox, in 1856.

TELEPHONY AND TELEGRAPHY.

A SENSITIVE RELAY.

BY D. B. GRANBY.

I NOTE in your issue of May 20 a description of a sensitive relay, the device of Mr. MacDonald, of Australia. In principle, this device is identical with one I have used for many years in bad weather in St. Louis. Herewith is an illustration of it, as I use it. By using a retractile spring on each side of the armature of an ordinary relay, its sensitiveness



A SENSITIVE RELAY.

may be greatly increased. The arrangement is particularly valuable on repeater relays.

I am glad to say that the necessity for using this device has rarely arisen during the past two or three years, owing to the high standard of insulation maintained on the wires of the Postal Telegraph-Cable Company.

A RAPID DEEP SEA CABLE REPAIR.

A MID-ATLANTIC ocean repair on the Pouyer-Quertier cable was recently effected in a very expeditious manner by the Telegraph Construction and Maintenance Company. It was all the more creditable, as it was on the much dreaded Flemish Cap, a spot so well known by all Atlantic navigators, and, when possible, always avoided by them on account of its frequent fogs and incessant gales.

This company's vessel, the "Seine," raised the St. Pierre end on May 15, spliced on a piece, payed out and buoyed it the same morning. She then proceeded 40 miles to the eastward, and on May 17 raised the Brest end, spliced on, payed out, and arrived near the St. Pierre buoyed end the same night; but a dense fog coming on, the cable had to be cut and buoyed. The fog lasted four days, and on the weather clearing, the buoys were sighted, after some hours' searching for them. Early on the morning of May 22, the two ends were spliced together and the repair completed.

This is claimed to be the quickest deep water repair ever made in the Atlantic, and had not the fog intervened, it would have been a marvellous one. The rapidity of the repair may have been aided by the fact of the "Francois Arago," which failed in repairing the break last winter, having left a mark-buoy, and this mark buoy was sighted by, and served as a mark for, the "Seine." The buoy which the "François Arago" had put on the St. Pierre end at the same time was not found by the "Seine." The break occured in June, 1895, and another vessel went out last Autumn, but returned without having effected the repair, although she cut into the cable to the eastward of the Flemish Cap.

The "Seine" on her way out from London had effected considerable repairs, 235 miles from Brest, on the same cable. She left London April 25, called at Havre for cable, remaining there three days, and after effecting the two repairs above named, got back to London May 30—exactly five weeks.

BOYS ON BIKES.—The American District Telegraph Company, of New York, has mounted a squad of its boys on bicycles, in natty uniforms and tan leggins. They are all experts, and will greatly expedite the service.

THE NEW YORK TELEPHONE CO.

The New York Telephone Company was incorporated on June 19 by the Secretary of State, with a capital of $16,000,000, to construct, buy, or lease lines of electric telegraph and telephone to be operated in New York City, and thence to Albany and Boston and the intermediate cities, towns, and places in New York, Massachusetts, Rhode Island and Connecticut; also across or under the North and East rivers and New York harbor to Jersey City, Long Island City, Brooklyn, and Port Richmond, S. I.; also through New Jersey to Philadelphia, and to the intermediate cities and towns; also from Long Island City and Brooklyn to Montauk Point, L. I., and to the intermediate cities and towns; also from Port Richmond, S. I., to all places in Staten Island, and also to other cities, towns, and places in the States mentioned, and to connect with other lines leading to places outside of the territory.

The incorporators are: Charles F. Cutler, of Morristown, N. J.; John H. Cahill, Joseph P. Davis, Thomas T. Eckert, William T. Bouchelle, James Merrihew, and William H. Wolverton, of New York City; William H. Forbes, John E. Hudson, of Boston; George J. Gould, of Lakewood, N. J.; John Jameson and Charles A. Tinker, of Brooklyn, and John Van Horne, of Bayonne, N. J. The capital stock is divided into 160,000 shares, and each of the incorporators subscribes for ten shares. The company paid the State a tax of $20,000 for the privilege of incorporation.

The directors of the new company named in the articles of incorporation represent the following companies: Western Union Telegraph Company, George J. Gould, Thomas T. Eckert, Charles A. Tinker, James Merrihew, and John Van Horne; American Bell Telephone Company, John E. Hudson and W. H. Forbes; Metropolitan Telephone Company, Charles F. Cutler, John H. Cahill, Joseph P. Davis, William T. Bouchelle, William H. Wolverton, and John Jameson.

Much interest has been aroused and much speculation is rife on the scope and objects of this new company, many surmising that it is the opening wedge to a closer union between the Western Union and American Bell interests. The directors promise to issue an official statement on the subject within a few days. In the mean time, we are able to announce that the Metropolitan Telegraph and Telephone Company, of New York, has been transferred to the new company.

SOCIETY AND CLUB NOTES.

SIXTH ANNUAL CONVENTION OF THE CANADIAN ELECTRICAL ASSOCIATION.

THE Sixth Annual Convention of the Canadian Electrical Association opened in the rotunda of the Board of Trade Building at Toronto, Canada, at 2:30 p. m., on Wednesday, June 17. The attendance was one of the largest in the history of the association.

Mr. A. B. Smith, superintendent of the Great Northwestern Telegraph Company, the president of the association, occupied the chair. The convention having been called to order, the president delivered a short address which was greeted with applause. The secretary-treasurer, Mr. C. H. Mortimer, read the secretary-treasurer's report.

Mr. E. Carl Breithaupt read the report of the Committee on Statistics.

The president stated that a great many new members had come in and he was gratified to know that many of them were central station men.

The first paper on the list to have been read was a paper on "Ocean Cables," by Mr. C. P. Dwight, but, owing to the large amount of time necessary to prepare such a paper, Mr. Dwight had not been able, owing to press of business, to prepare the necessary data.

Mr. George Black, of Hamilton, read a very interesting paper on "Acetylene Gas," which he illustrated by a small apparatus which he had improvised for the occasion. A very interesting discussion followed the reading of this paper. The convention adjourned at 4:30 p. m.

In the evening an illustrated lecture was delivered by Mr. James Miln, entitled "Radiant Matter," showing the development of the Röntgen ray, which very much interested and delighted the audience which assembled.

Thursday, June 18.—Morning Session.—President Smith again called the convention to order.

The question was raised as to where the next place of meeting should be held and after some discussion it was decided to hold the next annual convention at Niagara Falls in June, 1897.

The report of the Committee on Statistics brought in by Mr. E. Carl Breithaupt, was then discussed. Mr. Breithaupt suggested that as it was difficult at all times to get information with regard to prices, etc., and as central station men were very backward about giving information, a bureau of information be established and that the secretary, Mr. C. H. Mortimer, be paid a reasonable remuneration for taking charge of the same. The scheme suggested by Mr. Breithaupt was heartily concurred in by many of the members present. Mr. Mortimer very kindly consented to take hold of the scheme and stated that he would be willing for the first year to do the work gratis and until it was seen whether it would be a success, and if it should prove to be such that then the association could vote him some remuneration. The report of the Committee on Statistics on motion was received and adopted.

Mr. James Miln then read a paper entitled "Meters," which he illustrated by diagrams thrown upon a screen by a stereopticon. At the close of the paper it was actively discussed and many questions propounded by the members were answered by Mr. Miln.

The convention then adjourned until 2 o'clock p. m.

Thursday.—Afternoon Session.—The president called the convention to order, after which the election of officers and members of committees was proceeded with.

The members of the Committee on Legislation are as follows: Messrs. J. J. Wright, K. J. Dunstan, B. Powell, L. B. Macfarlane, F. H. Badger. Committee on Statistics—Messrs. E. Carl Breithaupt, John Yule and O. Higman.

The officers elected were the following: President, Mr. John Yule, of Guelph; Mr. L. B. Macfarlane, first vice-president; Mr. E. Carl Breithaupt, of Berlin, second vice-president; Mr. C. H. Mortimer re-elected to the office of secretary-treasurer.

As was customary, five members retired from the Executive Committee and the following five were elected to take their places: Messrs. Ross MacKenzie, Niagara Falls; A. B. Smith, Toronto; John Carroll, Montreal; Charles Hunt, London, and F. C. Armstrong, Toronto.

Mr. O. Higman spoke at some length on the question of the Government Inspection Act and the following committee were appointed to confer with the government to see whether some satisfactory arrangements could be made, as the present system of inspection was considered iniquitous by the members of the association: Messrs. J. J. Wright, P. C. Gossler, A. A. Dion, James Miln and E. Carl Breithaupt.

Mr. F. C. Armstrong then read a very interesting paper on "The Outlook for the Electric Railway," upon which considerable discussion followed.

As it had been arranged to hold an excursion and dinner at Lorne Park in the evening the convention adjourned at 4:30 for the purpose of enabling the members and their friends to take the boat for Lorne Park.

A very pleasant time was had at the park, where a group photograph of the members was taken.

Friday, June 19.—Morning Session.—The first thing on the programme for the morning was a paper on "Central Station Economics," by Mr. P. C. Gossler, of the Royal Electric Company, of Montreal. At the close of the paper considerable discussion followed, and it was conceded by all that this was one of the most valuable papers given at the convention.

The next paper on the list was "Power Transmission by Polyphase E. M. F.'s." As the time of the convention was limited, Mr. White Fraser, the author of the paper, kindly consented to give a synopsis of the paper, not taking time to read it in full. At the close of the paper some discussion followed.

The next was a paper on "Operating Engines without a Natural Supply of Condensing Water, or the Continuous Use of Injection Water," by Mr. E. J. Philip. Owing to Mr. Philip's unavoidable absence, the paper was read by Mr. Wickens. As the time for discussion on this paper was limited, and as the paper was considered to be a valuable one, it was decided to ask Mr. Philip to amplify his paper and present it at a future meeting of the convention.

After passing votes of thanks to the retiring officers, to authors of papers and others who had tendered courtesies, the association adjourned to meet at Niagara Falls in June, 1897.

STANDARD ELECTRIC RULES.

The Conference on Standard Electrical Rules which met in New York, on March 18 and 19, will not hold a meeting in June as was contemplated at the first meeting, as the Committee on Rules have not yet completed their report, and the meeting is deferred until a later date, probably in the autumn, of which due announcement will be made whenever a time is decided upon.

ANNUAL MEETING OF THE FRANKLIN INSTITUTE ELECTRICAL SECTION.

The electrical section of the Franklin Institute held its annual dinner on the evening of June 15, 1896. Among the prominent guests were Mr. John C. Trautwine, chief of the Water Bureau; Arthur Falkenau, president of the Engineers' Club of Philadelphia; W. H. Johnson, Russell Hawkins and E. A. Custer.

The president of the section, Mr. Clayton W. Pike, acted as toastmaster, and in addition to those already mentioned responses were made by Carl Hering, ex-president of the section; T. Spencer and William C. L. Eglin, vice-presidents; F. Uhlenhaupt, Jr., Paul Foster Leach and Dr. A. E. Kennelly.

LETTERS TO THE EDITOR.

FERRARIS AND ARNO'S SYSTEM OF DISTRIBUTION.

In your issue of June 3 you describe a supposed to be "new" system of distribution, by means of alternating currents. With all due respect to Professors Ferraris and Arno, allow me to say that my paper, read before the American Institute of Electrical Engineers, in 1894, contains the subject in a far broader way. No restriction is made therein to the number of phases of the transformed currents, nor to the frequency, but it is pointed out that from the single-phase source any kind of translating device may be supplied with its special current by the interposition of a phase splitting transformer, which in this particular case was a self-starting synchronous motor or motor generator.

It was shown that from the single-phase alternating current dynamo continuous currents, as well as bi-phase and polyphased currents, might be produced and distributed to translating devices, requiring currents of such character. Possibly some claims are made on the transformer described, but no means for starting the short-circuited armature of the transformer is shown nor described (if I am not mistaken). It would seen as if the armature had to be started manually or by some auxiliary device. LUDWIG GUTMANN.

Peoria, Ill., June 15, 1896.

INCANDESCENT LAMP PHENOMENON EXPLAINED.

I noticed in The Electrical Engineer of May 27 a letter by "O. C. R.," which I will endeavor to explain.

While making some X-ray experiments I had a peculiar thing happen. I was collecting static electricity from the belt of my alternator and neglected to ground the frame of the machine, whereupon my lightning arresters began to discharge.

Now, "O. C. R." probably has some ground connection near his belt and no path provided for the static charge on the frame of his machine, which would cause the lamp, when grasped firmly in the hand (thus forming a ground) to discharge from the filament. TOM LUDLOW.

Florence, S. C.

REPORTS OF COMPANIES.

ANNUAL MEETING OF THE ELECTRIC STORAGE BATTERY CO.

The annual meeting of the Electric Storage Battery Company was held at Philadelphia, on June 4, the feature of which was the report of its president, W. W. Gibbs. The substance of this was as follows: The gross sales of the company for the year 1895 were $328,231.40, and the margin of profit was $124,733, making the profits $126,951.87. The general expense during this period was excessive, due to the starting and general establishment of business throughout the country, aggregating $126,969.47, leaving a net profit for the year, after payment of all expenses, interest, etc., $2,982.40. The total plates made for the year amounted to 1,112,864 lbs. The increase of business operates to reduce cost per pound and the division of operating expenses over a greatly increased output produces a very greatly increased proportion of profit to business done. The gross business for the five months of the present year aggregates $415,000. The business for the year will amount to over $1,000,000, and a gross profit of over $600,000.

ANNUAL MEETING OF WASHBURN & MOEN CO.

At the annual meeting of the Washburn & Moen Manufacturing Company, held May 26, the old board of directors was re-elected as follows: President, William E. Rice; Vice-President, Treasurer and General Manager, Philip W. Moen; Directors, the above officials and George T. Dewey, Stephen Salisbury and Rockwood Hoar. It was voted to increase the capital stock from $3,500,000 to $4,000,000. A quarterly dividend of 2 per cent. will be declared.

WALKER CONSOLIDATION RUMORS DENIED OFFICIALLY.

For the past few weeks there have appeared in the daily press, and some technical papers, rumors, and in some cases specific statements, that the Walker Company, of Cleveland, had been bought up by the General Electric and Westinghouse companies, and, in fact, were a part of the large consolidated companies. We are informed by the officials of the Walker Company that there is not a word of truth in these statements and are authorized to deny them most emphatically and unequivocally. They admit that overtures have been made to them with a view to some arrangement of this kind, but that they have not been accepted. The Walker Company wish it to be distinctly understood that they are entirely independent of the General Electric and Westinghouse companies, and are now in a position to compete with them in all kinds of electrical business. An officer of the Walker Company goes so far even, as to state that they were recently offered the factory in Cleveland, now occupied by the Brush Electric Company.

The Walker Company will soon be in the market with a complete line of alternating apparatus for power and lighting, both of the vertical and horizontal type, and will be ready to enter any field of electrical work. They also report that they are making rapid progress with their arc light machines, and that they will soon have on the market a complete line of arc light apparatus, all of which work is now being done at their New Haven factory, the inside of which presents the appearance of a veritable forest of small tools for lamp work.

THE CATARACT POWER AND CONDUIT CO., OF BUFFALO.

The Cataract Power and Conduit Company, of Buffalo, has been incorporated, with a capital stock of $2,000,000, to furnish Buffalo with electricity. It is, in fact, to act as the distributing agent of the Niagara Falls Power Company, the same interests involved in the one supporting the other. The Buffalo concern will relieve the parent company of the necessity of a strict supervision of the sale and distribution of electricity in that city. The business in Buffalo will be conducted under a different name and the operations directly overseen, instead of being superintended from New York City or the office at Niagara Falls. The directors of the Cataract Power and Conduit Company are Daniel O'Day, E. D. Adams, Francis L. Stetson, Edward L. Wickes, Wm. B. Rankine, D. O. Mills and John Jacob Astor, all of New York City; George Urban, Jr., and Charles R. Huntley, of Buffalo.

The work of laying the conduits will be begun shortly, according to the plans and specifications filed by the Cataract Construction Company with the Buffalo Board of Public Works two months since. The main conduits will be laid first and the smaller streets will be supplied if the demand increases. The first conduit will be laid in Court street. The parent company is now busy at laying its transmission lines to Buffalo. By the terms of the franchise the power must be there by June, 1897. The main distributing conduits in Buffalo will be completed when the electricity is delivered at the city line.

LEGAL NOTES.

THE RIGHT TO SET RAILWAY POLES IN FRONT OF PROPERTIES.

On June 15 a decision was rendered in the New Jersey Court of Errors and Appeals in regard to the right of corporations to set poles in front of private properties without the consent of the owners. The decision answers the question in the affirmative.

The case was that of Mrs. Washington A. Roebling against the Trenton Traction Company. A trolley pole was erected in front of her mansion on West State street, despite her opposition, and the Court of Errors affirms the decision of the Supreme Court that ordinances granting such rights to trolley companies are not unconstitutional. If Mrs. Roebling can show special damages, the court says she may find redress by suing to recover.

INVENTORS' RECORD.

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED, JUNE 16, 1896.

Alarms and Signals:—

ELECTRICAL PILOT OR SIGNAL. H. H. Franklin, Brooklyn, N. Y., 561,982. Filed March 18, 1896.
An alarm adapted for use on board a vessel for determining the depth of water.

FIRE ALARM SIGNAL BOX. J. J. Ruddick, Newton, Mass., 562,-034. Filed Oct. 8, 1894.
A non-interference box intended for use in a system where a number of boxes are arranged in series in a circuit.

AUTOMATIC BLOCK SYSTEM. J. Shoecraft, Harveyville, Kan., 562,253. Filed Aug. 8, 1895.
Comprises a motor, stopping wheel driven from the said motor and provided with a lug adapted to engage the armature lever, a wind wheel shaft driven from the said stop wheel and carrying a wind wheel connected to a pawl and ratchet with the wind wheel shaft.

RAILWAY SIGNAL. F. McBrien, Newark, N. J., 562,318. Filed April 1, 1896.
Permits the rails of the track to serve as the only conductors connecting the sections.

ELECTRIC BURGLAR ALARM. H. Rohrdantz, Buffalo, N. Y., 562,325. Filed Jan. 30, 1896.
A time mechanism for actuating the detonating devices in various parts of the house.

Primary Batteries:—

PRIMARY BATTERY. R. P. Osgood, Salem, Mass., 562,019. Filed Sept. 30, 1895.
Comprises a copper cup provided with openings closed by fibrous material; a positive pole suspended within said cup and a partition of felt between said poles.

Conductors, Conduits, and Insulators:—

INSULATOR. T. Blankinsop and J. W. Brown, Martin's Ferry, O., 562,166. Filed March 24, 1896.
A glass insulator for wires, having a wire engaging groove, a screw stem reinforced with an embedded metal plug and a rim or jacket depending over the stem from the base of the groove.

TESTING JOINT FOR ELECTRIC CONDUCTORS. B. L. Toquet, Westport, Conn., 562,261. Filed April 14, 1896.
Consists of a frame connecting conductor ends, with an interposed insulation and an adjustable piece to make or break the electrical connection across the insulation.

Distribution:—

ELECTRIC DISTRIBUTING SYSTEM. R. R. Bowker, Brooklyn, N. Y., 562,209. Filed Feb. 27, 1896.
Means whereby a portion of a network of street conductors may be cut off from a supply station, or whereby a network of street conductors receiving current from two stations may be electrically divided into two parts receiving current from said stations, respectively.

Dynamos and Motors:—

DYNAMO ELECTRIC MACHINE AND ELECTRIC MOTOR. J. G. Germann and F. B. Downing, Erie, Pa., 562,179. Filed March 26, 1896.
Relates to frames for electric motors and dynamos.

Lamps and Appurtenances:—

PENCIL FOR ARC LAMPS. I. L. Roberts, Brooklyn, N. Y., 562,-030. Filed Oct. 31, 1895.
A cylinder of carbon with a core of a material containing chromium.

ELECTRIC ARC LAMP. M. S. Okun, New York, 562,090. Filed April 8, 1892.
An air-tight globe provided with a valve for the emission of gases, and details of lamp mechanism.

SAFETY LAMP. William Waegel, Philadelphia, Pa., 562,208. Filed Oct. 22, 1895.
The case inclosing the incandescent lamp is filled with carbonic acid gas under pressure.

ELECTRIC ARC LAMP. O. S. Lyford, Jr., Chicago, Ill., 562,313. Filed April 6, 1896.
The combination with an inclosing chamber normally sealed from the external air, of a porous diaphragm for securing the equalization of the external and internal pressures.

Measurement:—

ELECTRICAL ENERGY INDICATOR. T. Duncan, Fort Wayne, Ind., 561,977. Filed Nov. 11, 1895.
Comprises a movable wound armature, a commutator, and elastic brushes for neutralizing any vibration imparted to them.

Miscellaneous:—

ELECTROGALVANIC BELT. A. Dow, Wooster, O., 561,975. Filed Feb. 17, 1896.
Details of construction.

THERMOSTAT. E. S. Brazelton, So. Pittsburg, Pa., and T. J. Zoeller, Nashville, Tenn., 562,353. Filed May 1, 1895.
Comprises a frame having an annular groove, a section of a hollow sphere of thin metal having its perimeter flanged, a spring whereby it may be firmly clamped in place in such frame, and co-operating contact pieces.

DIAPHRAGM FOR ELECTROLYTIC PURPOSES. Martin Kiliani, Neuhausen, Switzerland.
Permeable membrane placed between an outer and an inner series of supporting lathes or bars.

Railways and Appliances:—

TROLLEY. J. H. Holland and P. F. Glazier, Indianapolis, Ind., 561,991. Filed Aug. 23, 1895.
Comprises a self-lubricating bushing for trolley wheels and a swivel connection between the wheel and the pole.

RAIL BOND OR CONNECTION. H. P. Wellman, Catlettsburg, Ky., 562,055. Filed July 9, 1895.
A bond wire having iron or steel terminals and a copper bar or connection electrically welded thereto at its opposite ends.

CONTROLLER FOR ELECTRIC CARS. E. A. Sperry, Cleveland, O., 562,100. Filed March 20, 1896.
A reversing switch, operating connections between the cylinder and the movable contacts of said switch, and means for reversing the relative movement of said contacts when the car is to run in the opposite direction.

TROLLEY FOR ELECTRIC RAILWAYS. M. T. Graf, Buffalo, N. Y., 562,132. Filed Jan. 14, 1896.
So constructed as to be readily removable from the yoke of the trolley pole.

ELECTRIC RAIL BOND. W. H. Wiggin, Worcester, Mass., 562,-107. Filed Aug. 28, 1895.
Employs a flexible connection between the two bond ends attached to the rail flanges.

ELECTRIC RAILWAY SYSTEM, ETC. C. Coerper, Cologne, Germany, 562,216. Filed April 4. 1896.
The car receives current from secondary conductors through transformers interposed between primary and secondary conductors.

TROLLEY WIRE SWITCH. S. D. Cushman, Akron, O., 562,356. Filed Feb. 25, 1896.
Consists of line and switch wire terminals, and a rocking tongue to bring either switch terminals in alignment with the main terminal.

EMERGENCY ELECTRO BRAKE. Benjamin F. Card, Brooklyn, N. Y., 562,118. Filed Feb. 6, 1896.
Details of construction.

Regulation:

REGULATING ALTERNATING MOTORS. A. H. Armstrong, Schenectady, N. Y., 562,062. Filed Jan. 11, 1896.
An induction motor having a revolving and stationary part, with a ratio of transformation other than one to one, and a switch adapted to interchange the terminals of the revolving and stationary parts.

Switches, Cut-Outs etc.:—

AUTOMATIC ELECTRIC SWITCH. W. S. Barstow, Brooklyn, N. Y., and R. Lindslay, Cleveland, O., 561,958. Filed June 5, 1895.
Movable parts are controlled in their movements by a motor.

CONTROLLER FOR ELECTRIC MOTORS. E. A. Bryant, Washington, D. C., 562,116. Filed April 18, 1896.
In combination with a suitable resistance coil or device, a lever provided with a contact arranged to vary the resistance included in circuit, as the lever is rocked and a reversing switch carried by the lever and adapted to be actuated by a lateral movement of the foot of the operator without rocking the treadle.

ELECTRIC SWITCH. J. F. McElroy, Albany, N. Y., 562,142. Filed Dec. 29, 1894.
A cylinder carrying a connecting plug at one end thereof in permanent electrical connection, with a source of supply through the axle thereof, brushes arranged to receive electricity from said plug, and a secondary plug in the periphery thereof adapted to electrically connect corresponding brushes, one of which is electrically connected with one of the first-named brushes.

Telegraphs:—

TELEGRAPHY. E. F. Law, London, England, 561,004. Filed Jan. 8, 1895.
A synchronous multiplex system, with special regulating devices.

Telephones:—

TELEPHONE SWITCHBOARD. G. S. Maxwell, Richmond, Va., 562,009. Filed March 17, 1896.
Means for automatically completing the local circuit of any subscriber's line.

TELEPHONE SWITCHBOARD. G. S. Maxwell, Richmond, Va., 562,010. Filed March 17, 1896.
Means to prevent the annunciator or drop from being operated by the influence of a current which might be sent into the line at the spring jack when another circuit line is connected therewith.

TELEPHONE SWITCH. G. S. Maxwell, Richmond, Va., 562,013. Filed March 25, 1896.
Either the call wire or the wire of the magneto system may be used by the subscriber to call the central office.

TELEPHONE SWITCHBOARD. G. S. Maxwell, Richmond, Va., 562,012. Filed March 20, 1896.
A table carrying spring jacks, switches and connecting plugs, and a board carrying annunciators and a transmitter, the said board and table being hinged together.

TELEPHONE SWITCH. G. S. Maxwell, Richmond, Va., 562,013. Filed March 25, 1896.
A circuit changing device in combination with a receiver and induction coil connected in series with each other, and in multiple with a magneto generator, bell and condenser, whereby the condenser is brought in or out of the circuit according as the circuit changing device is moved in either direction.

SYSTEM OF TELEPHONIC EXCHANGE.—Salomon Berditschewsky, called Apostoloff, London, England, 562,064. Filed March 23, 1896.
An improved system of telephone exchange, whereby any two subscribers may communicate without the intervention of any attendant at the central station and without increasing the number of wires beyond the double circuit generally used.

NEWS AND NOTES.

ALTERNATING ARC LAMPS WANTED AT BARTON, VT.

The electric light plant which the village of Barton has built has now been in successful operation for the past three months without the slightest interruption. It is said to be the longest line of transmission in the Eastern States, the distance from dynamo to substation being 14½ miles, operated at about 6,000 volts. So far the streets of the town are lighted only with a few temporary arc and incandescent lights. The city is in the market for alternating arc lamps of any manufacture with which to light the streets. Communications relating to arc lamps, and giving all possible details, will be received and should be addressed to Mr. Ernest Gonzenbach, electrical engineer.

Trade Notes and Novelties

AND MECHANICAL DEPARTMENT.

GARTON LIGHTNING ARRESTERS.

WE illustrate herewith several of the improved 1896 types of Garton lightning arresters, manufactured by the Garton-Daniels Electric Company, of Keokuk, Iowa. These arresters number among their many good qualities positive action, reliability, efficiency and durability. Fig. 1 represents the street railway station type, which is handsomely mounted on a base of white Italian marble. This improved type takes less than one ampere at 500 volts on a short circuit and after severe tests has been adopted by several large electric railways in Chicago and St. Louis. The Garton M. C. station arrester made for 52 and 104 volt secondary, 110, 220 volt three-wire, 500 volt-power, 1000 and 2000 volt primary circuits, are similar in appearance to that shown in Fig. 1. These are also made for two- and three-phase alternating and arc circuits of any voltage. Fig. 2 represents the Garton pole arrester, and the street car arrester is similar to it. Fig. 3 shows the station arrester mounted on a marbleized slate base. Any kind of base is furnished to match the switchboard. Fig. 4 shows a "kicking coil" which is designed to be placed one on each side of the circuit between the apparatus to be protected and the arresters. The inductive resistance thus introduced causes the discharge to go to ground through the arrester.

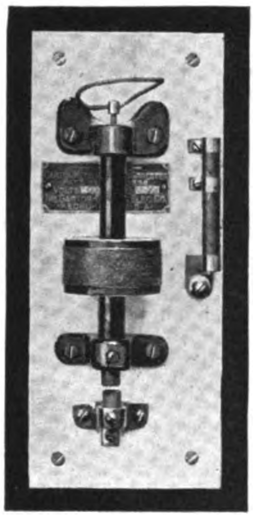


FIG. 1.

FIG. 2.

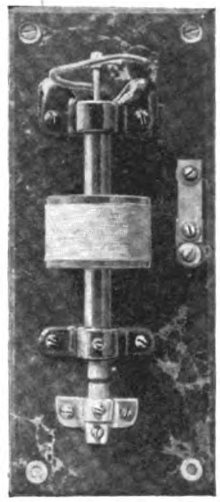

FIG. 3.

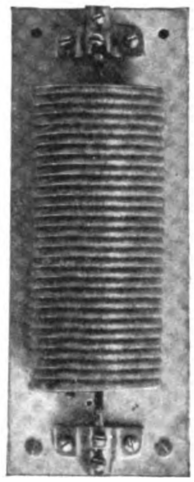

FIG. 4.

ECONOMIES IN COAL PRODUCTION.

The Jeffrey Manufacturing Company, of Columbus, O., have issued a catalogue of their mining machinery, with which is incorporated a paper by Mr. Cyrus Robinson, M. E., read before the joint meeting of the Western Pennsylvania Central Mining Institute and the Ohio Institute of Mining Engineers. The paper states that where a mine is free from gas and the roof ordinarily good, it does not require a very extended investigation to prove the advantage and economy of electricity over all other systems of power transmission for your coal mine. The following table, giving the cost of wire and pipe installed, based on the present market price of material and labor, shows very conclusively the superiority and economy of the electric system of transmission as compared with pneumatic:

Horse-power delivered.	Distance, in feet.	System of transmission.	Total loss in the line.	Cost of line installed.
100	5,000	Compressed Air.	10%	$2,350.00
100	5,000	Electric 250 Volts.	10%	837.50
100	5,000	Electric 550 Volts.	10%	280.00

Guided by the above figures the inclination would be to decide in favor of the electric 550 volt transmission, and if the vein of coal had an average thickness of not less than five feet, the decision would be correct.

MR. C. A. ECK, 116 Wooster street, has a very busy shop, turning out the many orders for his improved fan motors. Aside from these, Mr. Eck is also a manufacturer of larger dynamos and motors, all of which are his specialties.

SNOW STEAM PUMPING ENGINES.

A beautifully illustrated souvenir catalogue was issued by the Snow Steam Pump Works, of Buffalo, N. Y., on the occasion of the convention of the American Waterworks Association, in Indianapolis, Ind. The catalogue is not only an example of the highest art of the engraver, but contains a great deal of interesting and valuable information on the subject of pumping, from the primitive moss-covered bucket of our forefathers and the later town pump down to the largest triple expansion pumping engines which are now found doing service for municipal and other waterworks.

A number of the modern plants are illustrated, in which the Snow pumping engines are installed, among them being the plant at Fairhaven, Conn., in which the interior of the engine house is tastefully decorated with flowering plants, palms and tasteful rugs which leave the impression of a well-appointed drawing room rather than that of a pumping station. Several types of cross-compound horizontal pumping engines are shown, also the modern fire pump, compound duplex, low service pumps, double tandem compound pumping engines, sewage pumps and other special patterns too numerous to mention.

The interior of the Snow company's works at Buffalo is shown, in which the various parts of the pumping engines are under construction. The shop is equipped with traveling cranes and conveniently arranged machinery for manufacturing and handling the enormous castings which go to make up the large pumps for city service.

STOW FLEXIBLE SHAFTS.

The manifold uses to which flexible shafts may be applied are well illustrated in the catalogue of the Stow Manufacturing Company, just published. These shafts are of great importance as time and labor savers wherever, on account of the size, weight or position of the work, it is desirable to take the tool to the work instead of taking the work to the tool. Drilling, tapping, reaming, grinding and polishing are all accomplished by means of these shafts, which can be bent so as to bring the tools into almost any position relative to the work.

For drilling rails for bonding a combination flexible shaft and electric motor has been put on the market for the use of electric railway track builders and has met with excellent success. Another adaptation of this shaft is in the radial flexible bicycle drill, which is largely used, although it has been on the market only since the beginning of this season. Special tools of innumerable styles are also manufactured by this company for use in connection with these flexible shafts, and all machinery which it turns out is made on the interchangeable system.

THE SOUTHERN ELECTRICAL MANUFACTURING AND SUPPLY CO. ABSORBED BY THE GENERAL ELECTRIC CO.

The General Electric Company has purchased the stock of the Southern Electrical Manufacturing and Supply Company, of New Orleans, La., and has succeeded to the business thereof. The General Electric Company will increase the stock of the Southern company, and intend to extend the business.

A LARGE SHIPMENT OF WESTINGHOUSE APPARATUS.

ONE of the largest single shipments of electrical apparatus was shipped recently by the Westinghouse Electric and Manufacturing Company to Great Falls, Montana. The shipment filled eight freight cars and the freight on that cargo to its destination amounts to $8,000. The machinery will be used by the Boston and Montana Consolidated Copper and Silver Mining Company in the refining of copper and silver, and it is the largest machinery of its kind ever constructed for electrical refining purposes.

The Boston and Montana Company is one of the largest copper mining concerns in the Northwest. Until a few years ago

ELECTRIC TRAIN AT WESTINGHOUSE WORKS, BRINTON, PA.

the copper produced in that section was not refined, but the copper matte was sent east, and some of it to England, and then refined.

The Anaconda Mining Company purchased from the Westinghouse Company some time ago seven 360 horse-power generators, of an output of 3,600 amperes each at 75 volts. The machinery of the Boston Company will be driven by turbines from the waters of the Great Falls. The generators will be directly connected with the turbines. There are two of them, the largest ever made, each one of 1,100 horse-power, at an output of 4,500 amperes and 180 volts. These machines, as shown in the accompanying engraving, are shipped in four freight cars, while the others are filled with the detail apparatus, such as switchboard appliances, etc. The Westinghouse electric locomotive handled the train in the yards of the company, at Brinton, Pa.

SUSSMANN'S ELECTRIC MINERS' LAMP.

AN electric lamp has been recently introduced in England which has been tested with very satisfactory results by both mining and electrical engineers. The novelty of this apparatus lies entirely in the battery which feeds it, as the lamp itself is of the ordinary type. The battery plates are made by incorporating India-rubber and powdered pumice stone with the active material, by means of which additions the material is more firmly attached to the plate and at the same time greater porosity is obtained. In the second place, a solid electrolyte is used which is said to have considerably less internal resistance than others hitherto employed. This is made by adding finely powdered and dried cellulose to the sulphuric acid, the effect of the mixture being that the cellulose swells up and forms with the acid a stiff, thick paste. The battery as made measures over all 2¾ inches square by 8 inches high and weighs 3½ pounds. It will take a charge of about seven ampere-hours at six volts, making the energy of the charge 42 watt-hours. The average current during discharge is 0.53 ampere, and the variation in volts, toward the end of the discharge, is less than 5 per cent. The lamp can, therefore, be depended on to give an excellent and steady light for quite ten hours. It is being made by the Edison & Swan Company.

EDWARD P. SHARP.

Among the dealers in second-hand electrical supplies who have some real bargains at this time may be mentioned Mr. Edward P. Sharp, of Buffalo. His stock includes generators, motors, controllers, motor bearings, armatures, line material, etc. Everything is guaranteed to be in first-class condition and at prices to suit the closest buyer.

NEW YORK NOTES.

MESSRS. M'LEOD, WARD & CO., Thames and Greenwich streets, are meeting with a brisk demand for their Kinsman desk lights and portables. They also manufacture the well-known Ward spark arresters and safety insulators.

MESSRS. HUEBEL & MANGER, 286 Graham street, Brooklyn, N. Y., are running ten hours a day, with a force of about seventy men, turning out their many specialties, such as electric bells, push buttons and all kinds of household supplies. They report large orders, especially for their well-known skeleton bell, "Style F," and their iron box bells. Prospects look favorable for summer trade, their Mr. McChesney having recently returned from a very successful business trip.

THE old, well-known firm of Walsh's Sons & Co., Newark, N. J., are offering a promiscuous lot of dynamos, battery jars, lamps and other electrical goods both new and secondhand. This firm as dealers have exceptional facilities for handling and storing heavy electric machinery and supplies of all kinds, which puts them in a position to offer unusual bargains to the purchaser. Those interested would do well to follow up their advertisement from week to week in our "For Sale" columns.

THE HOGAN BOILER COMPANY are accumulating orders which will require a large addition to the company's manufacturing plant. Among them may be mentioned a second order for a 250 horse-power boiler for Mr. McDonald, the contractor for the Jerome Park reservoir, which came unsolicited and is to be credited to the merits of the boiler already installed. They have also received a second order from the Franklin Electric Illuminating Company, of Sea Cliff, L. I., and another of a 200 horse-power boiler for the National Starch Company, Glen Cove, L. I.

THE JOHN WENNSTROM COMPANY, 41st street, between 3d and 4th avenues, Brooklyn, N. Y., whose advertisement appears on another page, are the only large firm in this country making a specialty of manufacturing jewels for meters and all kinds of testing instruments. Their factory is running very busy also on diamond tools for all purposes and turning out shaving knives, recorders and reproducers for both the phonograph and graphophone. The factory is excellently equipped and arranged, and does great credit to Mr. John Wennstrom, the president of the company, who has been in the business for the past twenty years.

MR. CHAS. WACHTEL, proprietor of the Wachtel Electrical Manufacturing Company, has been in the electrical business for the past twenty-eight years. Since 1890 he has his factory located corner Hamilton street and New Jersey Railroad avenue, Newark, N. J., and reports a steadily growing business. Mr. Wachtel is the manufacturer of "The Leader" dynamo, which can be used for lighting or power purposes, also fans, fan motors and the "Wachtel" ceiling fan, which is highly recommended requiring, it is claimed, less power at very high speed than any other fan in the market. Mr. Wachtel is a manufacturer of other electrical specialties, and solicits repair work, winding armatures and furnishing parts for motors of all kinds, tools and dies for every purpose, etc., etc.

WESTERN NOTES.

THE BROWN HOISTING AND CONVEYING MACHINE COMPANY have just sold Messrs. E. D. Smith & Co., contractors, to be used on the work of extending the wheel pits of the Niagara Falls Power Company to accommodate seven more 5,000 horse-power turbines, two of their standard ten-ton locomotive cranes, fitted with extra large drums to take the great length of rope that will be required in hoisting out of the wheel pits.

THE WESTERN ELECTRIC COMPANY, Chicago, have removed their general offices from their old location on South Clinton street ,to the large new eight-story building which they recently erected on South Jefferson street, as an addition to their large factory, the location of the new building being also between West Jackson and Van Buren streets, but nearer the latter street. All the buildings are connected, and their factory is now one of the largest in the country.

THE CHICAGO BELTING COMPANY, Chicago, have recently completed the largest leather belt that has ever been made. It is 3 ply in thickness, 7 feet in width, 150 feet long, and weighs, 3,200 pounds. In its manufacture the selected portions of 450 oak-tanned hides picked from over 5,000 skins were used. There is not a stitch or rivet in the whole belt, glue being used exclusively as the adhesive substance. It has been purchased by the Louisiana Electric Light Company, New Orleans, La., where it will be attached to a 2,000 horse-power Atlas engine.

Department News Items will be found in advertising pages.

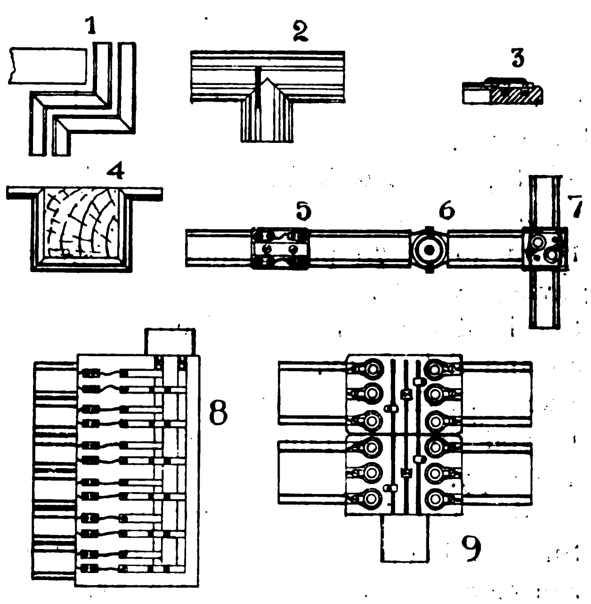
5725 Sheet 5.

WIRING IN MOLDING. B.

Accompanying engraving at 1 shows method of making an offset with molding around an obstruction; 2 shows method of taking branches from molding where cut-out is not required; 3 is cross-section of 2 showing how the wires of different polarity are crossed; 4 shows method of get-



ting around beams; 5 shows the method used in placing a main line cut-out; 6 a ceiling cut-out or rosette; 7 a branch block; at 8 is shown methods of bringing moldings to a panel-board, and at 9 is shown the method of assembling three-wire double branch cut-outs where moldings are used.

5762 Sheet 1.

TEST ON RAIL BONDING. B.

Characteristics per Mile, Double Track.

These estimates were made, not taking into account any earth leakage, the same as if the ground was frozen and giving relative electrical efficiency of some of the different methods of bonding.

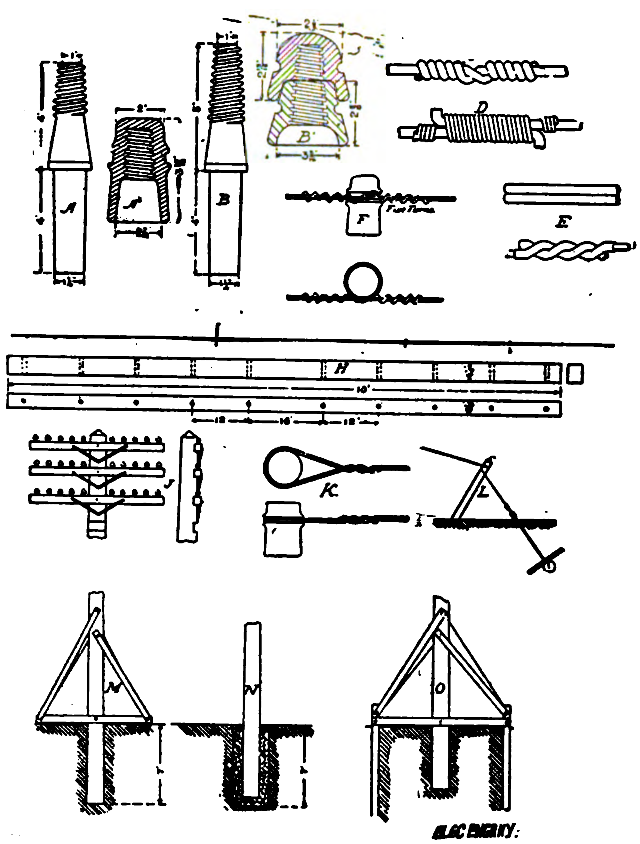
J. J. McTighe. Paper read before New York State Street Railway Association, September, 1893.

5751. Sheet 1.	TELEPHONE POLE LINE CONSTRUCTION.	B.



5751. Sheet 2.	TELEPHONE POLE LINE CONSTRUCTION.	B.

THE poles to be Michigan or Canadian cedar and of best quality live green cedar wood; butts cut squared at both ends, reasonably straight and well proportioned from butt to top and peeled, and knots trimmed close. The cross-arms to be well seasoned, straight grained Norway pine, thoroughly painted with brush and covered with two coats of Prince's metallic paint, consisting of seven pounds mixed with one gallon of pure linseed oil. All pins to be the best quality sound clear split locust, free from knots and sap-wood; standard pin to be 1¼ inches in diameter, as shown at A, No. 5751, Sheet 1. The transposition pin 1¼ inches in diameter, is shown at B; pins to be nailed to cross-arms with sixpenny galvanized iron wire nails driven straight from the middle of the side of the cross-arm as shown at H; pins to be spaced on the cross-arms, the two nearest the pole 16 inches apart and equidistant from the centre of pole; all others 12 inches apart. The standard cross country pole now consists of 35-foot pole having an ultimate capacity for four ten wire cross-arms. The gains for all cross-arms to be cut 4¼x½in. deep, before the pole is erected.

Line joints are made in galvanized wire; American Telegraph splice shown at C; D shows splice for copper wire; E shows the McIntire joint, which consists of two small copper tubes brazed together into which the ends of the wires are inserted, and the tubes twisted around each other; at F is shown top and side view of the proper manner of tying line wire to insulator, where copper wire is used.

LINE LOCATION:—Measure off and place stakes every 130 ft., locate poles as near stakes as possible; the heaviest poles should be placed on corners; the strongest and best looking poles distributed in thickly populated districts. A ⅝-inch hole should be bored through the centre of each gain at the time the cross-arm is placed in position. In a 30-foot pole line, on straight lines, the poles should be set in the ground 6 feet and on curves 6½ feet; the holes to be sufficiently large at the bottom to allow of using iron tampers all around the pole. On straight lines where poles

(*Continued on* 5751, *Sheet* 3.)

5751. Sheet 3.	TELEPHONE POLE LINE CONSTRUCTION.	B.

are equidistant, the cross-arms should be placed on alternate sides of the pole. At J, (5751, Sheet 1) is shown the method of roofing or champhering the top of the pole, which should be painted with same mixture as used for cross-arms; also method of bracing cross-arms with galvanized iron braces 1¼x28 in. long.

Clear glass insulator known as Standard pony insulator to be used and made as shown at A¹; transportation insulator also made as shown at B¹; at K is shown the method of dead ending and using ½ length of McIntire connector to secure end. At L is shown accepted method of anchoring the guy rod for a stub used for bracing of poles at curves and corners; M, N and O show methods of securing artificial foundations where ground is too soft to allow of proper tamping. To prevent line strains, poles are guyed by attaching guy wires near the bottom of the pole taking some of the strain to the top of the next pole. This parallel guying is sometimes carried back for three or four poles to distribute along the pole line a strain caused by a change of direction of the line.

Hard drawn copper line wire is now used for long distance telephone lines; the conductivity of copper is six times higher than iron; same line resistance will have ½ the weight with copper, and the speed of transmission is higher. The life of copper, especially near cities and on sea coast lines, is a great deal longer than galvanized iron.

The requirements of hard drawn copper wire for telephone work are as follows: For instance, take No. 8 B. W. G., diameter .1650 inches; maximum diameter allowed, .1660 inches, minimum diameter, .1640 inches; weight in lbs. per mile, 435.8; maximum weight, 441.1; minimum weight 430.5. A 200-lb. wire bar should draw a length of 2600 feet maximum; 1860 feet minimum; weight in lbs., maximum, 215; minimum, 153. Tensile strength 62,500 lbs. per sq. inch. Breaking weight required, maximum, 1335 lbs.; minimum, 1320 lbs. with elongation in 5 feet of 1 per cent. and to allow thirty twists in 6 inches without breaking. Conductivity required 97 per cent.; minimum to pass, 96 per cent.; pure copper taken at 100 per cent.

5714 Sheet 1.	CONDUCTIVITY OF ALLOYS.	B.

IN mixing two or more metals together, there has been found no definite law connecting the conductivity of the metals before mixing and the resultant alloy, but generally it has been found that the conductivity is below the mean of the metals entering into the mixture.

It will be seen by the tables given below, of the conductivity of alloys, that the combination of copper and zinc does not lead to as great a reduction in conductivity of the alloy as the combination of copper and tin. A column of figures is also given, with copper taken at twenty cents (20c.) per lb., and from this the value of the different compositions, as conductors, has been computed, when used for conductivity only. Of course, there are other considerations, such as cost of working and casting, which modify the price of the finished product, but it shows clearly that wherever copper can be substituted for composition, which is figured at a given current density, a large saving over the use of most any of the compositions can be effected. In table No. 3, the conductivities of some unusual alloys are given for comparison.

TABLE No. 1.

COPPER.	ZINC.	CONDUCTIVITY COMP'D WITH SILVER AS 100,0° C.	VALUE COMPARED WITH PURE COPPER AS CONDUCTOR @ 20c. PER LB.

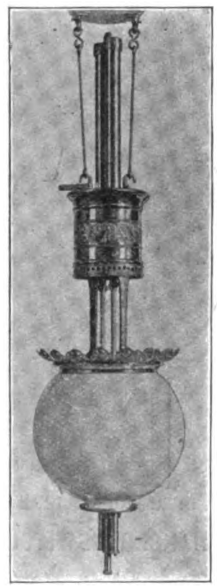
The Value ef Sterage Batteries in Central Station Practice

Has been demonstrated by

The Edison Electric Illuminating Co. of Boston. That Company installed its FIRST battery in March, 1894; it installed its SECOND battery in May, 1895, and it has just contracted for a THIRD battery.

THE ELECTRIC STORAGE BATTERY CO.
Philadelphia, Pa.

DOUBLE CARBON, Series ARC LAMPS



Ornamental Double Carbon Arc Lamp.

POINTS OF SUPERIORITY OVER SINGLE, LARGE CARBON ARC LAMPS.

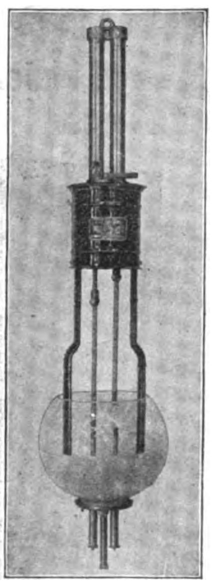
30 Per Cent. Economy in Operation.
No Energy Wasted in Heating Large Carbons.
Greater Volume of Light.
Most Rapidly Trimmed.
Lighter in Weight.

THOUSANDS OF OUR LAMPS BURNING IN ALL SORTS OF WEATHER FOR

FIFTEEN YEARS

ARE OPERATING AS SATISFACTORILY AS WHEN FIRST INSTALLED.

THIS IS NO NINETY DAY TEST.



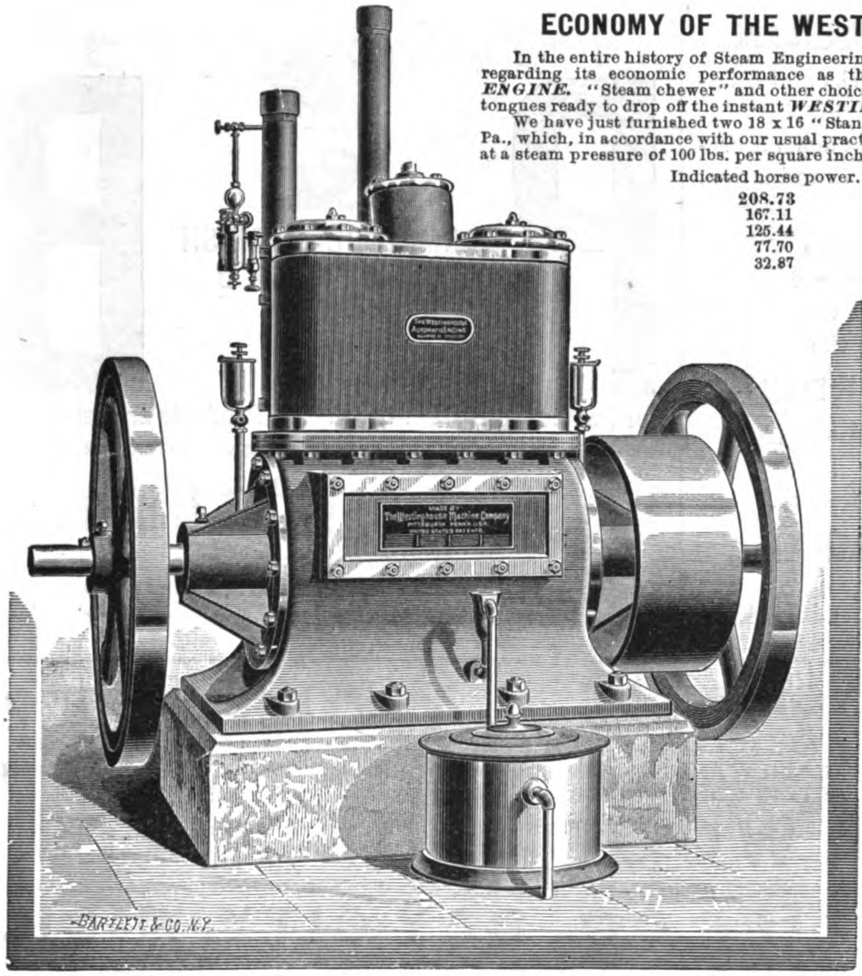
Plain Double Carbon Arc Lamp.

OUR DOUBLE CARBON ARC LAMPS

Start Promptly.
Feed Regularly.
Are Easily Adjusted.
Are Not Liable to Get Out of Order.
Burn Steadily.
Are Durable and Simple.
Operate at Low Cost.
Are Maintained at Slight Expense.

GENERAL ELECTRIC COMPANY,

SALES OFFICES IN ALL LARGE CITIES IN THE UNITED STATES. **SCHENECTADY, N. Y.** For Canada address Canadian Gen. Elec. Co. Toronto, Can.



ECONOMY OF THE WESTINGHOUSE "STANDARD" ENGINE.

In the entire history of Steam Engineering, probably no engine has been so industriously slandered regarding its economic performance as the *WESTINGHOUSE "STANDARD" AUTOMATIC ENGINE.* "Steam chewer" and other choice epithets, are always balanced on the tip of our competitors' tongues ready to drop off the instant *WESTINGHOUSE "STANDARD" ENGINE* is mentioned.

We have just furnished two 18 x 16 "Standard" engines to the Summit Branch R. R. Co., Wilkes-Barre, Pa., which, in accordance with our usual practice, were submitted to careful economy tests before shipment at a steam pressure of 100 lbs. per square inch, with the following results:

Indicated horse power.	Water per I. H. P. per hour.
208.73	26.68
167.11	28.05
125.44	28.24
77.70	31.40
32.87	40.50

There is no other single valve Automatic engine made which can duplicate the above results, and we believe it will bother the best four valve simple non-condensing engine to meet this performance over such a wide range of load.

We do not ask our customers to take the statement of any one in regard to the economy of our engines. Any purchaser may send his own expert and test his engine before it is shipped, and before he has incurred the expense of installation. No one else makes a similar offer. When we make a statement about the economy of our engines we mean it. That's the difference.

Send for little books on "Economy Guarantees" and "Testing."

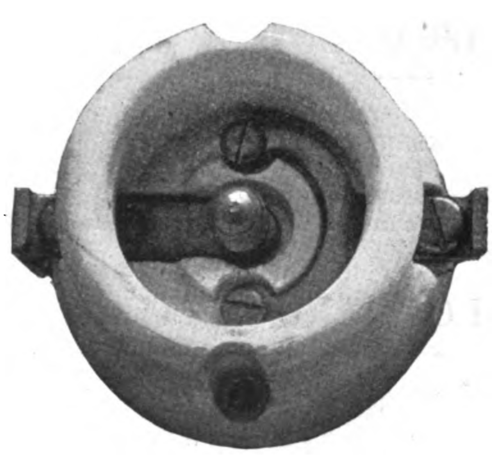
THE PERU PORCELAIN SOCKET AND PONY RECEPTACLE.

A new porcelain **Revolving Key Socket** for T.-H. System. Made for either cord or fixture attachments, and operated by a one-eighth revolution of corrugated centre for lighting or extinguishing. Newest, neatest and best on the market.

Peru Pony Wall Receptacle, made for T.-H. or Westinghouse systems, and with or without ring for supporting shade holder.

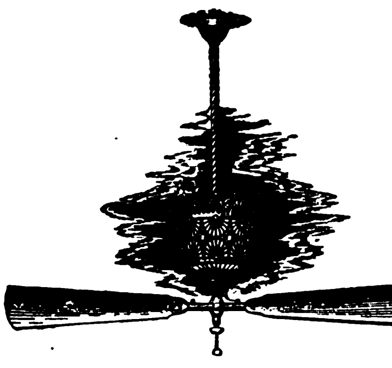
The quality, workmanship and simplicity for wiring of our goods cannot be beaten. Write for quotations.

Peru Electric Manufacturing Co.,
PERU, IND.



Ariel Alternating Current Fan Motor.

IS SHOWN IN THE ILLUSTRATION



IT IS Strong, Durable, Highly Efficient, Handsome, Noiseless. IT HAS no commutator; no winding on the armature; no chance to burn out; a blade shifter changing the angle of the blades without stopping. IT RUNS 125 revolutions per minute. THE MOTORS are of the well-known induction type. THE BEARINGS are self-oiling; the chambers once filled containing enough oil to last an entire season. MADE FOR alternating currents of 50 or 100 volts; 7,200, 14,000, to 16,000 alternations per minute. Write for Prices.

WESTERN ELECTRIC COMPANY,

TENDERS WANTED FOR TELEPHONE SERVICE

FOR THE CITIZENS OF TORONTO.

Sealed proposals will be received by mail, addressed to the Chairman of the Board of Control of the City of Toronto, up to the hour of 5 p. m., on the 15th day of July, 1896, for the privilege of constructing and maintaining a telephone services for the citizen of Toronto, for a term of five years or longer.

Parties tendering are required to supply their own specifications and plans. Further information may be obtained upon application to the undersigned.

For the information of tenderers, it may be necessary to state that the population of Toronto is 200,000.

R. J. FLEMING,
CHAIRMAN BOARD OF CONTROL.

CITY HALL, TORONTO.

The Electrical Exchange
1625 Monadnock, Chicago.

A RARE OPPORTUNITY FOR THE RIGHT MAN.

An important, responsible and rapidly growing electrical manufacturing company, situated in one of the Middle States, **wants immediately** an Electrical Engineer of ten or fifteen years' experience in designing electrical machinery. Must be capable of designing generators and motors of from 15 to 500 kilowatt capacity, both for alternating and direct currents, and must be a thoroughly competent up-to-date electrical engineer, and thoroughly conversant with all modern electrical engineering practice.

Address, G. B.,
Care The Electrical Engineer,
203 Broadway, New York.

WANTED.

A thoroughly competent and trustworthy Water Works or Gas Works Manager, or Electrical Engineer, with some capital, may learn of an excellent opportunity for securing control, on favorable terms, of the Water Works, Gas Works and Electric Light Works in a growing Southern city of about 7,000 inhabitants; County seat of one of the richest agricultural and stock raising counties in the blue grass section of the South. Highest references in regard to ability and integrity required. Address,

C. W. P.,
P. O. Box 708, New York.

WANTED.

An energetic business man to investigate a concern manufacturing electric motors and dynamos where money can be made, as the machines are the best, have been well introduced, a large number now in operation. They can be turned out as cheaply as any of the others, and all that is wanted is more capital and a good business man with it, who will take entire charge of the management of the concern, employ his own help without inteference, become a Director in the Company, and look after his own investment. Address

"S.,"
Care The Electrical Engineer,
203 Broadway, New York City.

FOR SALE.

One McIntosh & Seymour high grade, tandem compound, condensing engine; high pressure cylinder 13 inches, low 23 inches, stroke 17 inches, speed 210. This engine was used very little in electric station which was enlarged, and a much larger engine of same make substituted. It is in first-class condition, good as new, with heater. Address

The Lang & Goodhue Mfg. Co.,
Burlington, Vt.

FOR SALE

Entire Patent of Electric Clutch Controller, described in "Electrical Engineer" of March 25, '96. It is now in practical use and tested. Patent issued Nov. 26, 1895. A good chance for some clutch manufacturer.

J. E. STANNARD,
48 LEBANON ST., SPRINGFIELD, MASS.

WANTED.

Position as Superintendent of Construction with extensive electrical contracting firm. Wide experience in soliciting, estimating, designing and carrying out largest contracts for all classes of electrical work. Best of references.

Address, with terms,
G. H.,
Care The Electrical Engineer,
203 Broadway, New York.

FOR SALE.

At a bargain. Two 850-light dynamos, Edison patent, with Straight-Line engines to operate same. First-class condition. Will sell together or separately.

New York Electric Equipment Co.,
First Avenue and 33d Street, New York.

FOR SALE.

10 Type E series parallel controllers; 1 Edison 150-kilowatt 500-volt generator; 2 M. P. 75 500-volt generator; 10 G. E. 800-ring armatures; 50 sets S. R. G. motor bearings; 2,000 sheets mica strain insulators; 5 Edison No. 6 railway motors. This material, with the exception of the S. R. G. bearings and the strain insulators is all second-hand, but in first-class condition in every respect, and so guaranteed. Will be sold at very low prices. Edward P. Sharp,
44 Niagara St., Buffalo, N. Y.

WATER WHEELS

FOR HEADS OF 3 FEET TO 2,000 FEET.

Specially Designed and Adapted to

ELECTRIC POWER AND LIGHTING PLANTS.

Securing a **high guaranteed percentage** and **great steadiness** of motion, under variable loads. An **unequaled concentration** of power, and an **unprecedented high velocity.** Its **quickly operating balanced gates** affords **prompt** and **fine regulation** by governor. **Satisfaction guaranteed where others fail.** Write for Catalogue and state your wants.

JAMES LEFFEL & CO., Springfield, Ohio, U. S. A.

MISCELLANEOUS.

POCAHONTAS, VA.—The Southwest Virginia Improvement Company is putting in its machine shops an extensive electric power plant.

BALTIMORE, MD.—The subway commission has decided to accept the bid of the Standard Company to lay cables in sections 2 and 3 of the police and fire subway system, provided some minor changes can be made in the apparatus furnished without changing the specifications. The company's bid was $13,009.

ELECTRIC RAILWAYS.

BALTIMORE, MD.—The council on June 1 passed an ordinance authorizing the Falls Road Electric Railway Company to construct an electric line out the Falls Road, from Lafayette and Maryland avenues, to the city limits.

SPRINGFIELD, VT.—The town of Springfield has voted to bond itself for $30,000 toward building an electric road between that place and Charleston. The estimated cost of construction and equipment is $100,000.

FINANCIAL.

GREAT FALLS, MONT.—The stockholders of the Great Falls and Lewistown Telephone Company have declared a dividend of 16 per cent. on the capital stock.

PITTSBURG, PA.—The Westinghouse Electric and Manufacturing Company has declared a quarterly dividend of 1¾ per cent. upon the preferred stock, payable July 1. Transfer books close June 20 and reopen July 2.

BROOKLYN, N. Y.—The Edison Electric Illuminating Co., of Brooklyn, has declared a quarterly dividend of 1½ per cent., payable July 15. Books close June 30 and reopen July 16.

BALTIMORE, MD.—The first branch of council has passed the ordinance providing for the issuance of $1,000,000 bonds to construct a system of subways for electric wires.

BOSTON, MASS.—The American Bell Telephone Company has declared a quarterly dividend of $3, and an extra dividend of $1.50, payable July 15, to stock of record June 30. This makes extra dividends of $3 thus far for 1896, which is the same as last year, or at the rate of $15 per annum.

ELECTRIC LIGHT.

CANNON FALLS, MINN.—Cannon Falls will have an electric light plant. The village has granted a five years' franchise to D. and J. Valentine, who are now at work on the enterprise.

BLOOMSBURG, PA.—Bloomsburg has closed a five-year electric lighting contract for $80 a light. Pottsville pays $95 a light.

CATONSVILLE, MD.—The owners of the Catonsville Short-Line Railroad are considering a plan to operate electric trolley cars for carrying passengers and trains drawn by steam locomotives for hauling freight over the road. The line is owned by the Baltimore and Catonsville Construction Company and is operated by the Pennsylvania Railroad Company under a lease.

SCRANTON, PA.—The Citizens' Street Railway Company of Lackawanna County, capital $200,000, has been chartered to build a line through the principal streets of Scranton and Dumore, a distance of thirty miles. The directors are William L. Connellll, Plummer Page, Charles H. Schadt, Patrick J. Horan and Henry H. Archer, Scranton.

ALTERNATING CURRENT WIRING
AND DISTRIBUTION.

By WM. LEROY EMMET, Mem. A. I. E. E.

Cloth, 76 pages. Illustrated. Price, $1.00.

This is a most ***timely, useful*** and ***valuable book.*** It discusses the following important topics :—

Influences Affecting Alternating Distribution; Surface or skin effect; Counter E. M. F. of self induction; Explanation of harmonic variations; Energy and induction; Relation of current and E. M. F.; Electromotive forces; Diagrammatic representation of harmonic quantities; Nature of circuit of different classes; Other influences; Effect of transformers; Inductive resistance of lines; Relation of quantities; Practical determination by diagrams; Arithmetical determination; Step-up and step-down transformers; Determination for same; Interference of circuits; Multiphase systems; Three-phase systems and determinations; Two-phase systems; Alternate current wiring; Town lighting by alternating currents; Underground distribution, iron ducts, concentric cables, &c.; Low tension distribution; Effects of capacity; Graphic representation, &c.

The intelligent application of the principles contained in this pithy book will save the Electrical Engineer and Station Manager much time and money.

THE ELECTRICAL ENGINEER,

203 Broadway, New York City.

ELECTRIC LIGHTING PLANTS,
THEIR COST AND OPERATION.

By W. J. BUCKLEY.

CLOTH, 12mo, ILLUSTRATED, 275 PAGES. PRICE, $2.00.

This work is an invaluable compendium of data as to prices, costs, methods of operation, fuel, engines, oil, dynamos, pole lines, and a variety of other topics of first importance to the purchaser and user of electric lighting plants. While intended primarily for the buyer, it will be found extremely useful by the manager and electrical engineer.

Sent postage free to any address on receipt of price, by

THE ELECTRICAL ENGINEER, 203 Broadway, New York.

MISCELLANEOUS.

NEW YORK, N. Y.—The Acme Electric Lamp Company has been formed with $50,000 capital.

OLD TOWN, ME.—One of the electric launches, which have been purchased by the B. O. and O. Street Railway Company to be run on the Penobscot, has arrived. The launch is 35 feet long, 7 feet wide and has a capacity of 35 or 40 passengers. It is identical with those in use at the World's Fair, and was built at a cost of $2,700.

TELEPHONE.

PORTERVILLE, CAL.—The Mount Whitney Telephone and Power Company has ben formed to construct and operate a telephone line in Tulare County. Principal place of business, Porterville, Tulare County. Capital stock, $2,000, all of which has been subscribed. Directors, J. M. Gilstrap, Daunt; James Bursell, Globe; W. E. Sprott, A. M. Lumley, H. F. Brey, Porterville; Charles Rankin, Lindsay, and J. Sub. Johnson, Visalia.

MILWAUKEE, WIS.—Ripon Telephone Company; capital, $1,000; incorporators, M. S. Chittenden, L. E. Hall, G. F. Horner, H. P. Cody and Louis Pynch.

PARKER, S. D.—Articles of incorporation have been filed for the Houts Automatic Telephone Switch Company, of Parker, with a capital stock of $50,000; incorporators, W. A. Houts, F. E. Hayward, C. G. Pratt, B. W. Kumler, Vale P. Thielman

CENTREVILLE, WIS.—The extension portion of the Trempealeau telephone line, from Centerville to Arcadia, was sold by C. S. Utter to a syldicate of five citizens of Arcadia. The line was nearly completed when the sale ook place. The syndicate will build to Indèpendence, Whitehall, Blair, Waumandee, Montana and from Centerville to Bluff Siding, connecting with the Winona Telephone Company.

ROCHESTER, MINN.—Articles of incorporation of the Rochester Telephone Company have been filed with the secretary of state. The capital stock is placed at $20,000.

RENVILLE, MINN.—The Renville Consolidated Telephone Company has increased its capital stock to $10,000 and will at once erect a line from Renville to Olivia.

ORANGE, N. J.—The ordinance granting the New York and New Jersey Telephone Company permission to place its wires in underground conduits, has been passed.

NEW PORTLAND, ME.—The New Portland and Farmington Telephone Company has been organized at New Portland for the purpose of constructing and operating a telephone line from New Portland to Farmington, with $1,200 capital stock, of which $1,000 is paid in. The officers are: President, John Metcalf, of New Portland; treasurer, W. J. Trefethen, of New Portland.

YORKVILLE, S. C.—W. B. Moore has applied for a franchise for a telephone system.

See further, page xxiv.

ELECTRIC RAILWAYS.

NEW ORLEANS, LA.—An electric line, from the corner of Napoleon and St. Charles avenues to Metairie Cemetery, thence to the West End, is in contemplation by a number of prominent and wealthy citizens of New Orleans, who propose to give the uptown residents an electric route to the lake.

JACKSONVILLE, FLA.—The Panama Park Company has petitioned for leave to construct and operate an electric line.

ELGIN, ILL.—The electric road which is to connect Elgin and Aurora is expected to be finished as far as Geneva by June 20 and will be opened for business then. It is to be finished to Aurora this fall.

SKOWHEGAN, ME.—The railroad commissioners have made an official trip over the electric railway of the Somerset Traction Company, and have accepted the line as far as Madison Centre, a distance of five miles from Skowhegan. The balance of the road, from Madison Centre to Madison village, will be finished in a few weeks.

INDIANAPOLIS, IND.—The Citizens' Street Railroad Company, which now operates 100 miles of road, began an extension of its present line on May 25. The new line will run through Ninth street, Forest avenue, Twenty-second street, Greenwood avenue and Bellefontaine street.

MOUNDSVILLE, W. VA.—Work on the completion of the Moundsville, Benwood and Wheeling Railroad, from Moundsville to Benwood, a distance of thirteen miles, has been begun by Receiver Howard Hazlett, of Wheeling.

PITTSBURG, PA.—Construction work on the new Pittsburg and Mansfield Railway is to be commenced at once. During the past two years only enough work has been done to save the charter. The cost of the road is estimated at $1,000,000, a large part of which will be expended on the bridge and the tunnel. The work of changing the Fifth avenue road from cable to electric line began June 1. Nearly 1,000 cars, each equipped with 50 h.-p. motors, have been ordered. It is expected to complete the transformation before October 1.

See further, page xxvi.

ELECTRIC LIGHT.

NEWARK, N. J.—A verdict was rendered in the Circuit Court for $253.37 in favor of the plaintiff in the suit of the Newark Electric Light and Power Company against the Merchants' Express and Transportation Company.

PUEBLO, COLO.—THE Pueblo Electric Light and Power Company, capital $5,000, has been formed. H. Eugene Chubbuck, Irving Hall and Albert E. Pattison, incorporators.

PAWTUCKET, R. I.—The contract for putting an electric light plant at the No. 3 jumping station has been awarded to Duffy Brothers.

SILVER LAKE, N. J.—The contract for lighting the Silver Lake district with electric lights was awarded to the Kearney Electric Light Company.

AUGUSTA, ME.—The Kennebec Light and Heat Company are improving the facilities at their plant in Augusta by the introduction of a large turbine wheel.

ASBURY PARK, N. J.—The Atlantic Coast Electric Light Company has been incorporated by John E. Comins, Arlington, N. J.; Arthur D. Chandler, Orange, N. J.; John B. Summerfield, Brooklyn, N. Y. Capital stock, $50,000

NORTH ADAMS, MASS.—The North Adams Gas Company has made arrangements with the Fitchburg Railway to furnish the electric current to light the Hoosac tunnel. It will take a current of 1,100 volts, and to meet this extra demand the gas company will put in another boiler and substitute an engine of 400 horse-power for one of 350 horse-power. This will place the gas company in the position of having the largest electric plant west of the Connecticut River in Massachusetts.

MILWAUKEE, WIS.—The council committee on street lights decided to recommend the adoption of a resolution calling upon the city engineer to prepare estimates for a centrally located lighting plant.

Lafayette, Colo.—E. Cannon, who recently received a franchise to erect and operate an electric plant in Lafayette, has ordered his dynamos and other machines, and will commence the erection of his house at once.

BERKELEY, CAL.—The Berkeley Electric Lighting Company is about to erect a new $20,000 electric station on its property at the corner of Third street and Channing way, West Berkeley.

DECATUR, ILL.—Jefferson G. Millard and R. W. Hight have applied for a receiver for the Municipal Electric Company, alleging mismanagement and failure to make it yield best returns. The petitioners hold a mortgage on the plant, which is worth $75,000. Large improvements have recently been made.

MISCELLANEOUS.

PEORIA, ILL.—The Eagle Electric Works, Peoria, have been incorporated; capital stock, $5,000; incorporators, Frank Thone, Charles F. Nash, and Peter J. Bourscheldt.

KNOB RUN, O.—A complete electrical equipment is to be put in a large coal mine here.

PARKERSBURG, W. VA.—J. Blyth, a Pittsburg capitalist, has completed the purchase of 1,000 acres of valuable coal and timber land on the east side of the Elk River, about twenty miles above Charleston. The coal will be mined by machinery, using electricity as power.

NEW YORK, N. Y.—The X-Ray Manufacturing and Exhibition Co., of New York City, capital $10,000, has been incorporated. Directors, Cyrus O. Baker, of New York City; John A. Seely, Edward F. Peck, P. J. Bennett, of Brooklyn, and Fremont Wilson, of Yonkers.
